Mr. BARWELL was not sure that inert matter would not take on vital properties again, and thought that skin-grafting was an instance in point. In a recent case of a large burn, where the "grafts" did not take on the granulating surface, he had found that minute portions of the inner coat of the ox's aorta placed on the surface became converted into a distinct epidermis, others of them melting down into pus. He reminded Mr. Bryant that at the last meeting of the Society he had recorded twelve cases in which perfect occlusion had followed the use of the oxen ligature, and had been able to show the specimens from two of these cases; so that the flat ligature in no way resembled acupressure in its effects. The question as to the need for the division of the inner and middle coats was different now than when Dr. Jones wrote, for at that time ligatures were used which subsequently came away by ulcerating through the outer coats. Now, however, we have ligatures which can be left on the vessels, and which do close arteries permanently. It was essential that the animal ligature, whether tendon or not, should be used first, or should have been dried when fresh, for if putrefaction take place in it its characters are altered and its efficacy impaired.

Dr. B. O'CONNOR said that a short time ago he examined microscopically a mass of lymph lodged at the inner end of a drainage-tube, which had been removed by Mr. Lister. This lymph, which was not in contact with living tissue, contained distinctly small vascular branches. In reply to Mr. Page, he added that the drainage-tube had been *in situ* about four days.

Mr. DENT, in reply, said that the discussion showed that questions were still unsettled which had been thought to be determined by Dr. Jones. He mentioned that in one of Dr. Jones's experiments a septum was formed in the artery precisely like that lately described by Mr. Treves in a vessel tied by the carbolized catgut ligature. In the present case there was microscopical evidence that the inner coat had been ruptured, and that the artery was permanently occluded. In the subclavian artery, where only a tendon ligature was applied, the clots were not so large and well-formed as in the carotid, where two ligatures, one tendon and the other catgut, had been used. As to "organization," one of the specimens showed vascularizing lymph between the two occluded ends of the artery, at a distance from the tendon ligature; and he believed the view taken by Mr. Savory and Mr. Holmes was probably the true one. Mr. Stirling, who had brought these kangaroo tendon ligatures from Australia, had selected them because of the readiness with which they were prepared. Ligatures of whale tendon had also been suggested. Mr. Dent had used them as sutures, and found them too thin and too readily dissolved in the tissues. There was no reason why the same material should not be used as a round rather than a flat ligature; the great advantage claimed for it over catgut being the time it remains unabsorbed.

—

Treatment of Lupus by Scraping with Volkmann's Sharp Spoon.

The employment of Volkmann's sharp spoon for the treatment of lupus is likely to meet with more and more general acceptance. It presents several advantages over the older methods of dealing with these painful cases, which indeed are for the most part so unsatisfactory, that surgeons are often tempted to abstain altogether from interference of any kind. The principal merits claimed for this way of treating the disease are, in the first place, its extreme simplicity, and in the second, that it is possible to tell with great accuracy when the limits

f the affected parts have been reached. A tolerably sharp spoon should be used, vith a short strong handle, and the affected surface should be scraped until all he soft tissue has been completely removed. Nothing is more easy than to tell vhen healthy structures have been reached, by the sense of resistance they offer; nd, unless an unreasonable amount of force be employed, these cannot be ma-erially injured. If an extensive surface has to be scraped, an assistant is neces-ary, as considerable capillary hemorrhage frequently occurs.

The following method of procedure, according to Mr. RICKMAN J. GODLEE, *Med. Times and Gazette*, March 19, 1881) will be found effective in checking he bleeding. Several strips of lint having previously been prepared, the surgeon apidly scrapes a patch, not larger than can easily be controlled by a dossil of lint f a suitable size; this is firmly pressed upon the raw surface, and then another dealt with in the same way, and a second piece of lint is applied. The process then repeated until the whole of the affected part has been rendered raw. The ieces of lint are then, one after the other, removed, and if the bleeding has not ompletely stopped it will be found that a little iodoform powder dusted on the pot quickly arrests it in most cases; but if this should not be the case it is only ecessary to continue the pressure for a few minutes longer. A very comfortable nd satisfactory dressing for the after-treatment is an ointment formed of iodo-orm, eucalyptus oil, and vaseline, in the following proportions:—Iodoform, gr. x.; eucalyptus oil, ʒj.; vaseline, ʒj. This preparation, it may be mentioned, a very useful one in many forms of ulceration accompanied by a fetid discharge. is powerfully antiseptic, and at the same time extremely bland, so that it allows ealing to go on rapidly beneath it. The ointment may be spread conveniently n thin rag, which adapts itself readily to the inequalities of the face, or, if a larger pply be advisable, it may be put upon the surface of a piece of lint. In all the stances described by Mr. Godlee, the same method of treatment was pursued; sides presenting several features of some little interest, they serve to show how apidly severe cases of lupus may be, if not cured, at least very much relieved r a considerable length of time, and the disease held very much in check. ome of them also illustrate the fact that when the morbid condition appears to e quiescent, plastic operations may be undertaken without fear that the lupus lceration will affect the flaps or interfere with their union.

Midwifery and Gynæcology.

Myxoma Fibrosum and Cystic Disease of the Placenta.

Dr. C. BREUS contributes to the *Wiener Medizinische Wochenschrift*, an nteresting communication on the former of the above rare conditions. Myxo-matous growths are among the commonest of pathological changes which affect he chorion and placenta. They occur in three forms: the *myxoma papillare ultiplex*, which is the disease so long known under the name of the "hydatid nole;" another form, in which the morbid change is diffused in a flat, jelly-like ayer; and the form which he here more particularly describes—myxoma fibro-um. The name was given to the disease by Virchow. Dr. Breus has seen two ases; he has examined two other specimens put up by Rokitansky; and he efers also to cases described by Clarke, Hildebrandt, and Hodgen. From these ources he gives the following points as being what can be at present stated con-erning the disease. It forms tumours which may reach a considerable size—as ig as the fist—which are either single or few in number, surrounded by healthy

placental tissue, the boundary between the normal placental structure and the tumour being quite distinct. The tumours have often a kind of capsule of connective tissue, and are sometimes stalked, the pedicle consisting mainly of blood-vessels. The surface is uneven or ragged. On section, they have a fleshy, grayish-red appearance, and from their aspect have been repeatedly described as sarcoma. They are elastic in consistence. Microscopic examination shows them to consist of myxomatous tissue richly supplied with bloodvessels, and which is divided into small lobules by thick bands of connective tissue.

As to their causation nothing is known. Hildebrandt supposes them due to localized disturbances of the placental circulation. Dr. Breus is unable to accept this view, because he thinks that in an organ the circulatory system of which is so complex as that of the placenta, such disturbances must be very frequent, and the lesions so produced must be far commoner than is myxomatous change. These tumours do not exert any prejudicial influence on the course of labour, the most that can be said being that it is possible they may determine its premature commencement. They do not interfere with the life or development of the fœtus. During the detachment of the placenta they not unfrequently get separated from it, and so expelled separately. Should the placenta be adherent, the presence of such a tumour might surprise and puzzle the accoucheur who had to remove the placenta.

We may, in commenting upon this subject, call attention to the researches of FENOMENOW (*Archiv für Gynäkologie*) in the same field. He has minutely examined two placentæ, in which the most conspicuous morbid change was the presence of cysts. In one of them the whole fœtal surface was studded with cysts, in size from that of a hemp-seed to a hazel-nut, with bright, translucent contents. The cysts were about twenty in number, and were irregularly arranged. In the other case there was one pediculated cyst as big as a large orange, projecting from the fœtal surface; and beside this, that surface presented several solid nodules, some as big as a pigeon's egg. These nodules, examined microscopically, showed a structure like that in Dr. Breus's case—myxoma fibrosum. Before discussing the origin of the cysts in his two cases, Dr. Fenomenow gives some account of the literature of the subject. The kinds of placental cysts that have been described are—(1) gelatinous cysts, seated between the chorion and amnion, the credit of recognizing which is due to Millet; (2) perivascular cysts; (3) blood-cysts, springing from the placental sinuses, which have been described by Bustamonte; (4) cysts of the villi themselves, the results of degeneration; (5) hemorrhagic or apoplectic cysts—names given by Hegar and Mayer and by Hennig, respectively; (6) amnion-cysts, arising, according to Ahlfeld, from adhesions between the two layers of the amnion; and (7) colloid cysts described by Grazeansky. It is of course quite possible that some or all of these theories may be wrong; but the subject has been so little investigated, that whatever errors there may be in the observations, or the interpretations thereof, by the workers quoted, have not yet been corrected. Meantime, we must accept these statements as expressing all that we at present know, and as provisionally true. Dr. Fenomenow carefully considers the origin of the cysts in his own cases. In the first case he believes the cysts not to have been formed out of pre-existing cavities or canals, but to have originated in irritative processes in the tissue of the villi, leading to adhesion at places of the villi to one another, and the formation of closed cavities between them; then fluid had accumulated in these cavities, and distended them into conspicuous cysts. The cysts are therefore heterologous. As to the reason of the supposed irritative process, he can say nothing. The collection of fluid in the second case he attributes to mucous degeneration of the placental tissue, together with extravasation, the result of vascular degene-

ration. He can offer no suggestion as to the cause of this pathological process. We may add that lithographic plates illustrate Dr. Fenomenow's paper and increase its value.—*Med. Times and Gazette*, April 9, 1881.

Tupelo Tents for Dilating the Uterus.

A recent clinical lecture of Volkmann's collection, by Dr. LEOPOLD LANDAU (*Sammlung Klinischer Vorträge*, No. 187), is devoted to the consideration of the methods of dilating the cervix uteri. That which will be most novel to English readers is his strong recommendation of the tupelo tent. Sponge and laminaria tents are of course well known here; and of the later methods of rapid dilatation introduced by Fritsch and by Schroeder, Dr. Landau expresses disapproval. Tupelo tents are made from the root and stem of the *Nyssa aquatica*. Dr. Landau says that they expand more uniformly than laminaria tents, and that their co-efficient of expansion is somewhat greater than that of any other tent. In expanding they produce the same softening and infiltration of the uterine tissue as other tents. They are almost entirely free from any tendency to produce septic infection, and therefore antiseptic precautions need not be rigidly carried out when these tents are used. To effect dilatation, when one tent has been put in, it may be removed in three or four hours, when it will have expanded enough to allow a larger tent, or more than one, to be inserted. In this way the cavity of the uterus may be made accessible to the finger within twenty-four hours. Dr. Landau has used these tents in this manner for two years, and has never seen any disadvantageous result from their use.—*Med. Times and Gazette*, March 19, 1881.

Medical Jurisprudence and Toxicology.

On a Probable Cause of Lead Colic.

At a late meeting of the Royal Medical and Chirurgical Society (*Lancet*, March 12, 1881), Dr. C. HILTON FAGGE read a paper upon this subject. After referring to the fact that in certain observations on the nature of the lead line in the gums, published in the fifty-ninth volume of the Transactions, he had been anticipated by a French physician, M. Cras; the author remarked that both he and M. Cras had on theoretical grounds suggested that it was almost certain that sulphide of lead must be formed in the intestinal mucous membrane of persons exposed to the action of the metal, by the reaction of the sulphuretted hydrogen of the intestinal gases upon a soluble combination of lead circulating in the capillaries. The author had since had few opportunities of examining the bowel in patients who had had symptoms of lead-poisoning. In two instances the results were negative. In the other two instances a marked and extensive blackening of the interior of the bowel was observed. Dr. Stevenson was kind enough to make analysis of the discoloured contents of intestine, and to compare them with analysis of healthy pieces of intestine from the same patients, and he proved that there was an excess of lead in the blackened part, amounting in one case to as much as 320 times the quantity present in the non-coloured part.

Dr. DOUGLAS POWELL asked whether any microscopical examination of the intestine was made, as the precise seat of the deposition of lead might explain whether it occurred by direct action of the sulphuretted hydrogen on the lead in the bowels, or on the lead on the way to being eliminated by the large intestine after its absorption higher up. The treatment of lead colic by iodide of potas-

sium was generally followed up by purgatives, in the view that the lead is so eliminated.

Dr. R. THOMPSON said it was important to remember there were two ways in which the intestine might be blackened by lead. It may be that the metal is deposited in the mucous membrane from the blood, and converted into the sulphide by the intestinal gases, or that, like bismuth, it is acted upon by these gases before absorption. He had found in those who took bismuth that the mucous membrane of the large intestine was blackened by the sulphide of bismuth, which by means of chromic acid could be converted into the yellow chromate. He referred to Dr. de Mussy's observations on the Claremont cases treated by alkaline sulphide baths. The skin was blackened—a condition which Dr. Thompson had found in another case similarly treated to be due to the deposit of sulphide of copper, from the action of the solution in the metal of the bath.

Dr. POWELL added that Dr. Fagge's views as to the cause of the blue line on the gums were confirmed in a very marked case of lead paralysis without any such blue line being present. This absence of the blue line was associated in the case with a complete freedom from tartar on the teeth. It was well known also that no blue line appears on edentulous gums.

Dr. CAVAFY asked Dr. Fagge whether he regarded the deposition of the sulphide of lead in the intestine as the cause of lead colic, and, if so, did he think it acted on the nerves of the intestines. *Prima facie* there was no reason, if this were the case, why the deposition of the salt on the gum should not give rise to toothache.

Dr. A. W. BARCLAY pointed out that lead was undoubtedly absorbed into the blood, and its action was not merely local like that of bismuth. Was the lead only partially absorbed, or was it eliminated again into the alimentary canal, as Dr. Powell stated. The presence of the discoloration in the large intestine was due to the larger amount of sulphuretted hydrogen in that portion of the bowel. He presumed that lead colic had its seat in the small intestine, so that it could not be attributed to the existence of the deposit.

Dr. FAGGE, in reply, said that a microscopical examination was made in the first case, and showed the black granules to be deposited around the capillaries of the villi, just as on the gums. Dr. Thompson's remarks as to the discoloration of the intestine from bismuth were suggestive. Bismuth blackened the tongue, and Brinton suggested that it also produced a blue line on the gums, but this Dr. Fagge had not been able to confirm. The lead line was due to the deposition of the metal in the tissue of the gums, and its conversion into sulphide by the tartar. It was by following out the line of inquiry thus suggested that he had sought for discoloration of the intestinal mucous membrane, where a much greater amount of sulphuretted hydrogen would be in operation than in the gums. There was no reason to suppose that any large quantity of lead would escape absorption. He did not adduce the fact of deposition as explanatory of lead colic, which, however, had, he thought, its seat in the large intestine.

MEDICAL NEWS.

The Law of Copyright as Applied to Oral Lectures.

In the early days of the *Lancet* its enterprise among other forms took the shape of reporting the lectures of the eminent London teachers, whether they were willing or no, and in some cases even notwithstanding the express prohibition of some of them. Sir Astley Cooper even went so far as to lecture in the dark in the illusory expectation of thereby preventing reports being made. At last in 1824, having failed in every other way, Mr. Abernethy determined to invoke the aid of the law in the maintenance of his ownership of his lectures, and he sought to restrain by injunction the publication of his oral lectures delivered at St. Bartholomew's Hospital, on the ground of his absolute right of property in his lectures and his right to reap the pecuniary profits of his own ingenuity and labour. In granting the injunction the Lord Chancellor (Lord Eldon) expressed himself as "clearly of the opinion that when persons were admitted, as pupils or otherwise, to hear these lectures, although they were orally delivered, and although the parties might go to the extent, if they were able to do so, of putting down the whole by means of short-hand, yet they could only do that for the purposes of their own information, and could not publish for profit that which they had not obtained the right of selling." The *Lancet* immediately appealed, and announced that the contest had not been terminated and should not be until the highest tribunal in the country (the House of Lords) had decreed that the publication of these lectures was illegal.

In the next stage of legal proceedings it was stated to the Court of Chancery by the counsel for the *Lancet* that he was now given to understand that the motion for the dissolution of the injunction was not intended to be opposed and he therefore submitted that he was entitled to have the injunction dissolved, and it was so ordered. In commenting on this "triumph" by default, the *Lancet* says, "We do not claim the right of publishing the lectures of any individuals, except those who by an infamous by-law have procured for themselves a monopoly of lecturing to students in surgery,"—alluding to a law of the Court of Examiners, by which attendance upon lectures at certain hospitals (St. Bartholomew's among the number) was requisite to obtain a license to practise, and by which it was claimed Mr. Abernethy became a "public functionary for a public purpose."

Such is the history in brief of one of the most famous law suits in the

history of medical journalism, and as the injunction on the *Lancet* was finally dissolved by Mr. Abernethy's failure to continue the litigation, it is easy to understand how in recent times it has become a common belief among the ill-informed that the law upheld the *Lancet*, and that an author had no legal rights over his oral lectures which a journal was bound to respect; indeed, not long since one of our contemporaries gave editorial notice to very much this effect.

In this country the decisions of our courts have been in conformity with that of Lord Eldon in the *Lancet* case, and while a lecturer cannot lay claim to any vested right in the ideas he communicates, the law holds that the words and sentences in which they are clothed belong to him. Mr Justice McLean has decided that "lectures, oral or written, cannot be published without the consent of the author, though taken down when delivered; the person taking them down has a right to their use, but he may not print them," and that "any use of such lectures which should operate injuriously to the lecturer would be a fraud upon him for which the law would give him redress." And Mr. Justice Van Brunt has decided that "the delivery of a lecture to a public audience does not work a forfeiture of the common law right of property in a lecture."

Attention has been recently called to the law of copyright as applied to oral lectures by a suit which was brought by Messrs. G. P. Putnam's Sons, of New York, against Dr. Leo T. Meyer, to restrain him from selling his report of the anatomical lectures of Dr. Darling, they having published the lectures by arrangement with Dr. Darling. A few weeks ago Mr. Justice Van Voorst, of the New York Supreme Court, in granting the injunction, emphatically declared that the point "that lecturers may interdict the publication of their lectures has been distinctly decided."

So much for the law of the subject—of the morals it seems superfluous to speak—and it affords us no little satisfaction to say that the MEDICAL NEWS AND ABSTRACT has always acted in accordance with the only view which has over and again received judicial sanction, and that the clinical lectures which have appeared in our columns have always been authorized publications made by, or with the express permission of, their authors, and have been revised by them, and the right of ownership acknowledged by the tender of pecuniary compensation.

The decision in the case of Putnam *v.* Meyer will be gladly received by the many clinical lecturers in our hospitals and medical colleges, and will stimulate them to speedily put a stop to the unauthorized publications of their lectures which, owing to the frequent gross inaccuracies they contain, have proved as great a fraud upon the reader as they were upon the rights and reputation of the author.

American Medical Association.

The Thirty-second Annual Meeting of the Association was well attended, and the proceedings were harmonious. The President's address and the addresses of the chairmen of Sections were carefully prepared, were worthy of the occasion, and were well received. In the Sections the papers were meagre, notwithstanding the efforts of the chairmen to procure valuable contributions, and elicited no notable discussions. In the business sessions, interest centred around the amendment of the Code of Ethics, and the proposition to substitute a weekly medical journal for the annual volume of Transactions. Dr. Billings's substitute for the amendment to the Code was a happy conception, which to a large extent met the arguments of both sides, and at the same time filled the requirements of the case as fully as was probably practicable under any proposition. The action of the Association in relegating for further consideration the question of publishing a weekly journal was at least prudent. The publication of such a periodical involves a much larger annual outlay than it was apparent the Association had at its command, and therefore, with more wisdom than such large bodies usually display in business matters, it wisely deferred action until it had received more accurate information upon which to form a sound judgment than the committee had been able to lay before it. The selection of a President for the ensuing year was happy, and was a proper recognition of the value of Dr. Woodward's labours, as well as those of the Army Medical Staff, in behalf of medical science.

During the sessions of the Association the *Virginia Medical Monthly* issued a daily edition, giving a full and accurate report of the proceedings of the day before. To it we are indebted for aid in the preparation of our report of the proceedings of the Association.

To the local committee of arrangements much credit is due for the careful and painstaking way in which they successfully managed the details of the business and pleasure of the Association. The well-known reputation for hospitality which Richmond has always enjoyed was more than maintained, and this year's meeting will long be memorable to those who participated in it for the unbounded hospitality, both public and private, which was extended to the delegates by the physicians and citizens of Richmond.

—

Proceedings of the American Medical Association, Richmond, Va., May 3, 4, 5, *and* 6, 1881.—The American Medical Association convened in thirty-second annual session at Mozart Hall, in the city of Richmond, Va., on Tuesday, May 3d, at 11 A. M., John T. Hodgen, M.D., of St. Louis, President, in the chair. The session was opened with prayer by the Rt. Rev. Bishop Keane, and the Association was welcomed to Richmond by Dr. Frank Cunningham, of Richmond, Chairman of the Committee of Arrangements, and by the Hon. F. W. M. Holliday, Governor of Virginia. The President then delivered his Annual

Address, which was an earnest and able advocacy of conservative surgery, and was received by the Association with marked evidence of approval.

Section I. (*Practice of Medicine*, Dr. William Pepper, of Philadelphia, Chairman.) In a paper upon "Bloodletting as a Therapeutic Measure in Pneumonia," Dr. W. C. Wile, of Sandy Hook, Conn., advocated the free use of the lancet, in which he was supported by Drs. N. S Davis, of Chicago; Post, of New York; Quimby, of Jersey City; Whitney, of New York; and S. D. Gross, of Philadelphia. Drs. J. J. Lynch, of Baltimore; Whittaker, of Cincinnati; Octerlony, of Louisville; and Lester, of Detroit, took opposite ground.

Section II. (*Obstetrics and Diseases of Women*, Dr. James R. Chadwick, of Boston, Chairman.) Dr. Paul F. Mundé, of New York, made some "Practical Remarks on the Use of Pessaries," and the subject was discussed by Drs. Beverly Cole, of San Francisco; Albert H. Smith, of Philadelphia; H. P. C. Wilson, of Baltimore; Maughs, of St. Louis; and Quimby, of Jersey City. Dr. Wilson dwelt upon the importance of ascertaining whether the uterus can be lifted up before introducing any pessary, and expressed his disapproval of stem pessaries.

Section III. (*Surgery*, Dr. Hunter McGuire, of Richmond, Chairman.) Dr. J. H. Warren, of Boston, read a paper "On the Use of Various New Surgical Instruments;" and Dr. Wm. A. Byrd, of Quincy, Ill., reported "A Case of Ulceration and Perforation of the Appendix Vermiformis, with Remarks upon Abdominal Section in cases of Perforation of the Bowel," in which he advocated operative interference in inflammatory affections around the cæcum. Dr. J. E. Reeves, of Wheeling, presented from Dr. B. W. Allen, of Wheeling, a report of a case of nephritic calculus weighing 480 grains, which had caused a pyonephrosis with a large fluctuating tumour on the hypochondrium. By aspiration 18 pounds of sero-purulent fluid were evacuated, with temporary relief. The patient died, and on autopsy the left kidney was found to have been converted into a sac, 15 inches long, 12 inches wide, and 6 inches deep, containing ten pounds of purulent fluid, together with the above-mentioned calculus.

Section IV. (*State Medicine.*) In the absence of the chairman, Dr. J. S. Reeve, of Wisconsin, this section adjourned.

Section V. (*Ophthalmology, Otology, and Laryngology*, Dr. D. S. Reynolds, of Kentucky, Chairman.) Dr. G. T. Stevens, of Albany, described a "Registering Perimeter." Dr. W. C. Jarvis read a paper on "Nasal Catarrh, with Hypertrophy," and advised the removal of the hypertrophied tissue by the écraseur, and in the case of sessile growths with the aid of transfixion needles. Dr. J. J. Chisolm, of Baltimore, read a paper on the "Treatment of Conical Cornea," in which he advocated puncture of the cornea with a red-hot needle, as advised by some French surgeons.

Section VI. (*Diseases of Children*, Dr. A. Jacobi, of New York, Chairman.) "The Importance of Physical Measurements in Children" was the title of a paper by Dr. H. P. Bowditch, of Boston. He said that it seemed probable that the accurate determination of the normal rate of growth in children will not only throw light upon the nature of the diseases to which childhood is subject, but will also guide us in the application of therapeutic measures. Dr. Bowditch exhibited a chart representing the case of a child, between two and three years old, in which careful and systematic weekly weighing showed, first, the approach, by some weeks, of a chronic disturbance of nutrition, represented by enlarged cervical glands and clay-coloured stools; and, second, after recovery, the approach of an attack of measles, the "danger signal" of progressive loss of weight preceding the eruption by at least a week.

Dr. Lee, of Baltimore, remarked that he had paid especial attention to this subject, and had noticed that a female child could lose more in proportion to its

weight, without detriment to its health, than a male child of the same age. He also said that if the loss of weight preceding an eruptive disease was excessive, the case was so much more grave in its prognosis, and that this loss of weight preceded this eruption by from four to five days.

Dr. Busey, of Washington, read a paper on "The Relation of Meterological Conditions to the Diarrhœal Diseases of Children;" and Dr. James C. White, of Boston, forwarded a paper entitled "Some of the Causes of Infantile Eczema, and the Importance of Mechanical Restraint in its Treatment." He described the many and varied external influences which immediately affect the skin of the new-born, as being a common cause of eczema, and laid especial stress on the fact that heat was the more usual cause of the disease than cold. These external influences, however, furnish but a small proportion of all the cases of the disease which occur at this period of life, although by far the great part of those concerning the etiology of which we have any posititive knowledge. During the last twelve years he had treated at the Massachusetts General Hospital 5000 cases of eczema, of which 1770 occurred in children of ten years of age and under, and of which the largest proportion, viz., 569 cases, was in the first year of life. Eliminating the operation of the causes directly acting upon the skin from without, above mentioned, and a few other extraneous agencies, the parasitic chiefly, Dr. White did not hesitate to say that he knew nothing whatever of the causes of the disease in the remainder; also, that as far as his experience went, eczema affected all classes of society alike, occurred at all seasons of the year, came in children of all degrees of health, in the perfectly sound as frequently as in the feeble; that it had no necessary connection with any other disease of childhood; that it showed itself in an equal proportion in bottle babies and those reared at the breast, and was independent of diet; also, that if there were other assigned causes, he would here say that his observation gave him no justification for believing any of them.

After speaking of the extreme suffering which the little patients undergo, Dr. White said that the prime factor of the treatment was the prevention of scratching, and he advocated controlling the child's movements by a system of swathing in a pillow-case, by which the same chances of success in the therapeutics of infantile eczema is given, as exist in the adult. He said that when the strait-jacket treatment is carried out, the child soon becomes used to the confinement, and a wonderful improvement takes place in the disease.

Dr. L. Duncan Bulkley, of New York, believed that Dr. White had laid far too much stress upon local causes, and had ignored entirely the influence of internal, general, dietary, and hygienic causes. Internal treatment he believed to be to a certain degree absolutely necessary, and without it physical restraint would be comparatively ineffective. He advocated the internal use of small purgative doses of calomel every other day, and a mild alkali, as acetate of potassa in liquor ammoniæ acetatis, with a little nitre, and perhaps aconite. As regards mechanical restraint, if the itching is relieved, it is not required; and if it is not relieved, such confinement is torture beyond description. Diachylon ointment Dr. Bulkley believed to be very inefficient in arresting itching. Tar in some form was far more efficacious; indeed, he had little to desire in the way of an application to infantile eczema beyond the following ointment: ℞. Unguenti picis, ℥j; zinc oxid, ʒij; unguenti aquæ rosæ, ℥iij. Mix. This should be very carefully prepared and very thoroughly and abundantly applied. If it appears stimulating, less of the tar ointment may be used. He laid great stress upon employing the rose ointment and not simple cerate, or lard, or vaseline, or petroleum. The ointment should be made of a consistency to spread easily and yet not to all melt away after application.

Dr. Bulkley was very positive in the directions given in regard to the use of water to eczematous surfaces in children: they were only to be washed according to direction, and that very rarely, often only at intervals of several days; moreover, it was all important that the protective ointment should be replaced *immediately* after the surface is dried, and renewed sufficiently often to keep the parts completely protected, even twenty or more times the first day. On covered parts the ointment may be thickly spread on the woolly side of sheet lint and bound on. Among the hundreds of cases he had never covered the face with a mask, and had rarely been obliged to restrain the infant much after the first day or so. The only restraint he had ever practised, was putting on muslin mittens, tied around the waist, and then tapes from these passed behind the back or beneath one leg.

Dr. D. H. Goodwillie, of New York, read a paper on "Thumb-sucking."

Second Day. General meeting. The Committee on Nominations was announced, and the Association then proceeded to the consideration of the proposed Amendment to the Code of Ethics, Art. I., paragraph 1st, by adding "and hence it is considered derogatory to the interests of the public and honour of the profession, for any physician or teacher to aid in any way the medical teaching or graduation of persons knowing them to be supporters and intended practitioners of some irregular and exclusive system of medicine."

Dr. Marcy, of Massachusetts, moved to lay the amendment on the table. Lost. Dr. E. S. Dunster, of the University of Michigan, then addressed the Association in a speech carefully prepared, in opposition to the amendment. Dr. N. S. Davis, of Chicago, moved that the amendment be made the special order after the addresses on Thursday. Dr. Howard, of Maryland, moved as a substitute, that the matter be indefinitely postponed. The substitute was lost, and the motion of Dr. Davis adopted.

Dr. William Pepper, of Philadelphia, delivered the Address in Medicine which was devoted to the consideration of the great importance of local lesions, and especially catarrhal inflammation of mucous membranes, as forming the essential cause of many apparently obscure diseases, and also as adding greatly to the danger of many diseases which are now regarded as due exclusively to the presence of some specific poison in the blood.

Dr. James R. Chadwick, of Boston, delivered the Address on Obstetrics and Gynæcology, in which he directed attention to a statistical consideration of the literature of his specialty during the past five years.

Dr. John H. Packard, of Philadelphia, from the Committee on Journalizing Transactions, presented an elaborate and carefully prepared report upon the subject which closed with the proposal of the following resolution.

Resolved, That the President be authorized to appoint a committee of five to digest and report in detail as soon as practicable upon the time, place, and terms of the publication of such a journal, to elect an editor, fix his salary, and to arrange all other necessary details.

Dr. N. S. Davis, of Chicago, moved to strike out so much of the resolution as related to the election of an editor. Adopted.

Dr. Marcy, of Mass., moved that as many of the previous committee as were present at the meeting, be members of the new committee. Adopted.

Dr. Toner, of Washington, moved to add the Secretary and Treasurer to the Committee. Adopted.

Dr. Toner, of Washington, offered a resolution instructing the Secretary to publish with the forthcoming report of the Transactions of the Association an index of all the previous volumes. Adopted.

Dr. Toner presented the report of the Committee on Necrology.

Section I. (*Practice of Medicine.*) Dr. D. W. Prentiss, of Washington, presented a paper entitled "Is croupous pneumonia a zymotic disease?" and Dr. W. C. Dabney, of Charlottesville, Va., a paper on the "Nature and Treatment of Pneumonia." Dr. L. Duncan Bulkley, of New York, read an elaborate paper on "The Diet and Hygiene of Eczema."

Section II. (*Obstetrics and Diseases of Women.*) Dr. H. P. C. Wilson, of Baltimore, exhibited some instruments, which gave rise to a spirited discussion upon instrumental interference. He showed some dilators by the use of which he is enabled to dispense with the use of tents. Dr. Albert H. Smith, of Philadelphia, expressed a preference for the tents: he said, the instruments make small lesions about the cervical canal, hence the dangers of septicæmia in careless hands. The tents, he thinks, are safer, if not withdrawn before the end of forty-eight hours instead of twenty-four, as is usually done. The tents ought to be cylindrical (not conical), and should be rubbed over with moist soap and dipped in a solution of salicylic acid before being introduced.

Section III. (*Surgery and Anatomy.*) Dr. C. F. Stillman, of New York, described some "new mechanical appliances," and Dr. Alfred C. Post, of New York, read a paper on "Plastic Operations on the Face." Dr. D. H. Goodwillie, of New York, also read a paper on the "Treatment of Arthritis of the Temporo-maxillary Articulation," by means of an apparatus to relieve the joint of pressure on the inflamed articular surfaces. It is made as follows: an impression of the teeth of either jaw is taken and an interdental splint made, the posterior part of which is raised a little for the purpose of a fulcrum, on which the back tooth of the opposite jaw rests. Another impression is taken of the chin, and a rubber splint is made to fit it. A skull-cap is next made to fit the head closely, with elastic bands on each side passing down from it and fastened to the chin-splint. The interdental splint is placed in position in the mouth, and the back teeth of the jaw closed on the fulcrum of the interdental splint; then, when pressure is made on the chin by tightening the elastic bands connecting the skull-cap with the chin-splint, the joint is relieved from pressure. Dr. Goodwillie reported some successful cases thus treated.

Dr. B. A. Watson, of Jersey City, N. J., read an elaborate paper, the title of which was "An Experimental and Clinical Inquiry into the Etiology and Distinctive Peculiarities of Traumatic Fever."

Section IV. (*State Medicine.*) In the absence of the Chairman, Dr. J. S. Billings, U. S. A., was elected chairman *pro tem.*

Dr. J. L. Cabell, of the University of Virginia, read an interesting paper on "The National Board of Health and the International Sanitary Conference of 1881." He reported that there was good reason for hoping that an international agreement may be arrived at between the States most frequently threatened with epidemic invasions. And. aside from this, the degree of attention which as a result of the deliberations of the Conference has been given to the subject of maritime sanitary police, cannot be without fruit in securing greater cleanliness, better ventilation of ships sailing on the high seas; and in general, an improved sanitary condition of these important instruments of commerce, which become so often the carriers of the most deadly contagion, from the failure to use such precautions as sanitary science suggested, and as it is hoped will now be enforced among the maritime powers of the world.

Dr. C. F. Folsom, of Boston, read a paper on the "relation of the State to the insane." He argued in favor of the establishment of State Lunacy Boards. Among the points made were, first of all, that a lunacy board should embrace men with a thorough knowledge of insanity and its treatment. The chief duties of this board should be to secure proper care for the insane in private dwell-

ings, where they are very much liable to neglect. Secondly, they should examine the commitment papers, and otherwise looking into the cases, so as to be able to tell whether the lunatic should be retained for care or be discharged.

Section V. (*Ophthalmology, Otology, and Laryngology.*) Dr. Carl Seiler, of Philadelphia, read a paper upon "Syphilitic Laryngitis," and Dr. Chisolm one on a form of tinnitus induced by a rhythmical contraction of the tensor tympani muscle. Dr. Eugene Smith, of Detroit, presented a report of a successful operation for blepharoplasty, in which the graft was taken from the arm without any pedicle.

Section VI. (*Diseases of Children.*) Dr. R. J. Nunn, of Savannah, forwarded a paper on the "Treatment of Diphtheria." Dr. E. H. Bradford presented an article on "resection of the tarsus in severe congenital club-foot."

Third Day. General meeting. On motion of Dr. S. D. Gross, of Philadelphia, the By-laws were amended so as to establish an additional section to be known as the Section of Dentistry. A motion to suspend the rules so that the section might be organized immediately was objected to, and therefore could not be considered.

The President announced as the Committee on Journalizing the Transactions Drs. J. H. Packard, N. S. Davis, J. S. Billings, L. A. Sayre, and R. B. Cole, with the Treasurer and Secretary.

Dr. Hunter McGuire, of Richmond, delivered the address in surgery, and chose for his subject "operative interference in gunshot wounds of the peritoneum," which he advocated as exchanging an almost certain prospect of death for at least a good chance of recovery. He urged operative interference in gunshot penetrating wounds of the peritoneum with intestinal injury, in penetrating wounds of the peritoneum with any visceral lesion, and in similar cases without visceral injury. The wounds in the abdominal walls should be enlarged, or the linea alba opened freely enough to allow a thorough inspection of the injured parts. Hemorrhage should be arrested. If intestinal wounds exist, they should be closed with animal ligatures, trimming their edges first if they are lacerated and ragged. Blood and all other extraneous matter should be carefully removed, and then provision made for drainage. If the wound of entrance is dependent, drainage may be secured by keeping this open. If the wound is a perforating one, and the aperture of exit dependent, the patency of this should be maintained, and, if necessary, a drainage tube of glass or other material introduced. If there is no wound of exit, and the wound of entrance is not dependent, then a dependent counter-opening should be made and kept open with a drainage tube. If it is urged that the means suggested are desperate, it can be said in reply that the evil is desperate enough to justify the means.

In the absence of the address of the chairman of the Section on State Medicine, Dr. J. S. Billings, U. S. A., occupied the allotted time with some interesting remarks on some of the results of the tenth census as regards mortality statistics.

Dr. N. S. Davis, of Chicago, from the Committee on Clinical Observations and Records, presented an elaborate report in which the appointment of a standing committee was recommended. The report was accepted and the recommendation adopted.

The Committee on Nominations presented the following report: *For President*, Dr. J. J. Woodward, U. S. A. *For Vice-Presidents*, Dr. P. O. Hooper, Ark.; L. Conner, Mich.; Eugene Gressom, North Carolina; and Hunter McGuire, Virginia. *Secretary*, Dr. Wm. B. Atkinson, Penn. *Treasurer*, Dr. R. J. Dunglison, Penn. *Librarian*, Dr. Wm. Lee, Washington, D. C. *To fill vacancies in Judicial Council*, Drs. S. N. Benham, Penn.; J. M. Toner, Washington; D. A. Linthecum, Ark.; William Brodie, Mich.; H. D. Holton, Vermont; A. B. Sloan, Missouri; and R. B. Cole, Cal.

St. Paul, Minn., was selected as the place for the next meeting; and Dr. Stone was appointed chairman of the Local Committee of Arrangements.

Dr. Billings, U. S. A., moved the adoption of the report of the committee; and paid a high compliment to Dr. Woodward, the nominee for President, and thanked the committee, in behalf of the Medical Staff of the Army, for the high compliment paid it in the selection of one of its most honoured members for the highest position in the gift of the Association.

The report of the committee was unanimously adopted.

The next order of business was the further consideration of the amendment to the Code of Ethics. Dr. N. S. Davis, of Chicago, made an able and elaborate argument in reply to Dr. Dunster and in favour of the amendment, and Drs. Martin of Mass., and Dunster, of Mich., spoke against it. Dr. Marcy, of Mass., moved to lay the amendment on the table, defeated; and the further consideration of the amendment was postponed until Friday.

The next business was the consideration of the following amendment to By-laws, offered by Dr. J. M. Keller, of Arkansas:—

"In the election of officers and appointment of committees by this Association and its President, they shall be confined to members and delegates present at the meeting, except in the Committees of Arrangements, Climatology, and Credentials." The amendment was adopted.

Section I. (*Practice of Medicine*). Dr. Whittaker, of Cincinnati, read a paper on the "treatment of diphtheria," and advanced the view that diphtheria was first a local and afterwards a general disease, and that it is only when the epithelial barrier is broken down that the blood and the body become infected. He contended that, although he could not kill the germs of the disease in the throat, he could so condense its mucous membrane as to make it a dam to the influx of disease, and to this end he recommended the persulphate of iron in full strength, applied well up behind the velum palati.

Dr. I. E. Atkinson, of Baltimore, read an exceedingly valuable and interesting paper on the "production of albuminuria by use of iodide of potassium in syphilitic disease," and Dr. Henry A. Martin, of Boston, a paper on "variola vaccinæ and variola equinæ in Massachusetts."

Section II. (*Obstetrics and Diseases of Women.*) Dr. Jos. Tabor Johnson, of Washington, read a paper on the "diagnosis of pregnancy in early months," and Dr. Mundé, of New York, exhibited a curette for removal of adherent placenta after abortion.

Section III. (*Surgery.*) Dr. Charles A. Leale, of New York, presented a paper on "facial carbuncle, and its treatment," in which he recommended free incision and the thorough application of pure nitric acid.

Section IV. (*State Medicine.*) No meeting.

Section V. (*Ophthalmology, Otology, and Laryngology.*) The afternoon was occupied by a general discussion of the subject of astigmatism.

Section VI. (*Diseases of Children.*) Dr. Clarence J. Blake, of Boston, presented a paper on "middle ear disease in children in the course of the acute exanthemata." Dr. A. Jacobi, of New York, Chairman of the Section then delivered his address.

Fourth Day. General Meeting. The President announced the following as the "Committee on Clinical Observations and Records," Drs. N. S. Davis, of Chicago; J. M. Toner, of Washington; H. O. Marcy, of Boston; W. H. Geddings, of Aiken; and S. M. Bemiss, of New Orleans.

The Association resumed the consideration of the amendment to the Code of Ethics, and Dr. J. S. Billings, U. S. A., offered the follow ing substitute:—

"It is not in accord with the interest of the public or the honour of the profession that any physician or medical teacher should examine or sign diplomas or certificates of proficiency for, or otherwise be especially concerned with, the graduation of persons whom they have good reason to believe intend to support and practice any exclusive and irregular system of medicine." The previous question was moved, and the substitute was adopted.

The Committee on Nominations presented the following additional report:—

Section on Practice of Medicine—Chairman, Dr. J. A. Octerlony, Kentucky.

Section on Surgery and Anatomy—Chairman, Dr. J. C. Hughes, Iowa.

Section on Obstetrics—Chairman, Dr. H. O. Marcy, Massachusetts.

Section on Medical Jurisprudence and State Medicine—Chairman, A. L. Gihon, Washington, D. C.

Ophthalmology, Otology, and Laryngology—Chairman, Dr. D. B. St. John Roosa, New York.

Diseases of Children—Chairman, Dr. S. C. Busey, of Washington.

Dentistry—Chairman, Dr. D. H. Goodwillie, of New York.

On motion of Dr. Grissom, of N. C., a honorarium of $1000 was voted to the Permanent Secretary.

Dr. Goodwillie, of New York, offered an amendment to the Constitution, enabling permanent members to vote. Laid over for one year.

Dr. D. S. Reynolds delivered the address on Ophthalmology, etc.

The report of the Treasurer showed a balance of $2,208.40.

The report of the Committee on Publication was presented.

The Librarian reported that 273 titles had been added to the library during the year, and asked for an appropriation of $200 for current expenses, and that an appropriation of $50 be made in aid of the publication of the index medicus. Accepted, and appropriations passed.

The Convention unanimously adopted the following:—

Resolved, That the thanks of this Association are hereby tendered to the Committee of Arrangements of this Association for the faithful attention they have given to their duties and requirements; to the medical profession and citizens of Richmond for their hospitality and endeavours to make the time spent by us while here pleasant and agreeable; to Drs. McCaw and McGuire for the elegant special entertainment given by them at the Westmoreland Club; to Mr. McClure, Superintendent of the Telephone Company, for special facilities given the Committee of Arrangements and the Association; to Vice-President Parsons, of the Richmond and Allegheny Railroad, for his kind invitation for a free ride on his road to show us the interior of the State of Virginia; to Mr. Powell, manager of the Richmond Theatre; to the managers of the Mozart Association, and all others who have contributed to our pleasure and comfort; to the press, and especially their reporters, in giving such a full *résumé* of the proceedings in the daily papers; to the railroad companies generally who have so liberally reduced the rates of transportation for our benefit and any other modes of conveyance that have so contributed; to Mr. Valentine for his kind invitation to his studio.

Be it Especially Resolved, That our thanks are particularly due to the ladies of Richmond for attention and kind interest in making our sojourn so very pleasant and agreeable.

The Association then adjourned to meet at St. Paul on the first Tuesday in June, 1882.

The Association was entertained on Tuesday evening by Dr. and Mrs. McCaw and Dr. and Mrs. Hunter McGuire at a very handsome reception at the Westmoreland Club; on Wednesday evening by an operatic performance (The

Doctor of Alcantara), tendered by the physicians of Richmond; on Thursday evening by the citizens of Richmond at a promenade concert at the Richmond Theatre; and on Friday afternoon by an excursion along the valley of the James River, by the Richmond and Allegheny Railroad Company.

—

The American Surgical Association.—The American Surgical Association met at Richmond, May 5th, at the Hall of the House of Delegates. Dr. S. D. Gross, of Philadelphia, presiding, and J. R. Weist, of Indiana, acted as Secretary.

At the request of the President, Dr. Packard, of Philadelphia, read the proposed new Constitution and By-Laws. On motion of Dr. Davis, the Constitution and By-Laws, as read, were unanimously adopted Under this Constitution, surgeons known as "specialists" are allowed to become members of the Association. Under the old Constitution, that class of surgeons were excluded.

Drs. Marcy and Martin, of Boston, and Watson, of Jersey City, were recommended for membership.

Dr. Packard, the Treasurer, reported that he had received $925 from members, which, with the interest ($9.25), was deposited to the credit of the Association.

An amendment to the Constitution was adopted, to the effect that all nominations for membership shall lie over until the next regular session.

The Oriental Hotel, Coney Island, New York, was selected as the place for the next annual meeting. The 13th, 14th, and 15th of September was selected as the time.

The Association then adjourned until the above time and place.

The following is the list of officers of the society:—

Samuel D. Gross, M.D., President; Vice-Presidents, Drs. L. A. Dugas, James R. Wood; J. R. Weist, Recording Secretary; W. D. Briggs, Cor. Secretary; John H. Packard, Treasurer.

Council—Drs. Moses Gunn, John T. Hodgen, Hunter McGuire, J. C. Hutchison, Samuel D. Gross, J. R. Weist, and R. A. Kinloch.

—

American Medical College Association.—This body convened at Richmond on May 2, Dr. S. D. Gross, of Philadelphia, President, in the chair. Owing to the absence of a quorum, the Association adjourned from time to time until May 4, when a quorum was finally secured.

On motion of Dr. Bodine, of Louisville, the regular order of business was suspended to enter upon the election of officers. Dr. Gross stated that he would under no circumstances accept a re-election. The following officers were then elected:—

President, Professor J. M. Bodine, of the Medical Department of the University of Louisville, Ky.; Vice-President, Professor W. T. Briggs, of Nashville, Tenn.; Secretary and Treasurer, Professor Leartus Conner, of Detroit, Michigan.

Secretary Conner's report was then presented and received. It shows an increase of two in the active membership of the Association since the last annual meeting. From the reports of the several colleges made to the Secretary, it appears that these institutions had conformed more universally and completely with the requirements of the Association than heretofore, and that everything pertaining to their connection with the body was entirely satisfactory.

The report of the Committee on Medical Colleges showed that sixty-four catalogues of colleges had been examined, and that only sixteen of them had failed to come up to the Association's requirements in the matter of graduation. It

also appeared that twenty-two of the colleges had surpassed these requirements in one or more of the three following particulars: First, matriculation examinations; second, nine months' regular attendance; third, the three regular terms required.

After the transaction of some unimportant business, the Association adjourned until 5 P. M.

Upon the assembling of the Association at half-past five o'clock, it was found there was no quorum present. After waiting some time, and a quorum still being needed, the body adjourned, subject to the call of the President.

—

Health of New York.—The city's sanitary condition is far from satisfactory, and the mortality is constantly increasing. During the first four months of 1880 there were 9266 deaths. This year, during the same period, there were 12,420 deaths, and the number for the week ending May 14th was 822. Typhus fever still prevails, although not to so alarming an extent as during the first month of the endemic. This fact may be fairly attributed to the energetic and efficient measures for disinfection and isolation adopted by the health board. During the fourth week of the fever's prevalence, ending April 16, there were 68; in the fifth week, only 4; in the sixth week, 17; and in the seventh week (ending May 1st), 29 cases reported. On May 10th there were 63 cases of typhus, and 156 of variola, at the Riverside Hospital. The Shiloh lodging-house, in which the fever originated, will probably soon be vacated by order of the Health Department. The type of the fever is still mild.

Diphtheria has decreased slightly during April, but measles, scarlet fever, and smallpox have markedly increased, the number of cases of variola being double that for March, and four times that for February. Several cases of variola have been imported by European emigrant steamers, and some cases have been discovered in Brooklyn and Jersey City. There is no truth in the sensational report that several cases of Asiatic cholera had been observed in the city. Some apprehensions having been excited by the apparently impure condition of the Croton water, the Board of Health has promulgated a report to the effect that no injury can result from its use, as it contains no harmful ingredients. The supply of water is, however, inadequate to the increasing demand, caused by the advent of summer, which was announced by the occurrence, on May 10, 11, and 12, of about thirty cases of insolation, several of which were fatal. No progress whatever has been made by the Legislature with reference to the passage of a street-cleaning bill since the last issue of the MEDICAL NEWS AND ABSTRACT. Conference committees were appointed, by the Senate and the Assembly, for the purpose of framing a bill which would be acceptable to their respective houses; but, having failed to effect a compromise, were discharged. New conference committees will now be appointed. The grand jury has indicted the members of the police board for failure to properly clean the streets. The trial before the Mayor of these officials for the same offence has just been completed.

—

Bellevue Hospital.—Important improvements are about to be undertaken at Bellevue Hospital which will materially alter the appearance of its grounds. Mr. Marquand, a philanthropic capitalist, is about to present the hospital with a beautifully finished and appointed pavilion, in token of his appreciation of the care and attention bestowed upon his brother, who has been a recent inmate of the institution. The dimensions of the pavilion, which will be erected at the corner of Twenty-sixth Street and First Avenue, within the hospital inclosure, will be 120 by 130 feet, and the estimated expense of its construction about $20,000. It will be

hiefly devoted to the treatment of women and children, but four separate rooms ill be fitted up, in a remote portion of the building, for the exclusive use of ova-iotomy cases. The new building will consist of red brick and blue stone. The nterior, which will be planned in accordance with suggestions from some of the isiting physicians, will be finished in rosewood. The floors will consist of tiles. he bath-rooms and closets will be of the most approved pattern. The unsightly one wall, now inclosing the grounds upon the corner to be occupied by the new avilion, will be replaced by an iron railing.

The Commissioners of Charities and Correction are now having erected another ew pavilion, at the water's edge, for the treatment of erysipelas cases. Its imensions will be 90 by 36 feet, and its cost $6000. Its fire-proof walls and artitions will consist of two layers of corrugated sheet-iron, the interval between hich will be filled with plaster-of-Paris. This pavilion will accommodate enty-four patients. A median partition will separate it into male and female epartments, which will be thoroughly ventilated and provided with all modern nveniences. The new building will be ready for occupation on June 15th.

A small temporary reception hospital has been constructed at Bellevue Hos-ital for the detention and isolation of typhus fever cases, presenting themselves the examining office, until their removal to the typhus pavilions on Blackwell's land. It is built upon a scow which is anchored at a certain distance from ore. It is a one-storied building, and has separate apartments for males and males. Nurses, provided by the Board of Health, are in attendance, and the ospital steamer calls twice a day to remove patients to Blackwell's Island. The ospital is perfectly ventilated and provided with every convenience. The plan a floating hospital was adopted in order to prevent the communication of typhus ver to the inmates of Bellevue Hospital.

—

Prosecution of Unqualified Practitioners.—The Medical Society of the County New York has begun active legal proceedings against illegally registered and qualified medical practitioners by the arrest of two persons, who are accused practising medicine without physicians' licenses. The censors of the society ve ample evidence against a number of illegally registered practitioners, and opose to prosecute them as soon as the present cases shall have been disposed of.

—

The Street Cleaning Agitation in New York.—At the regular meeting of the edical Society of the County of New York, held on April 25, 1881, and at at of the Medico-Legal Society, on May 4, 1881, resolutions expressing the mpathy of the respective societies with the citizens' street cleaning bill were nanimously passed, and the presidents and secretaries of the societies were mpowered to endorse the resolutions, and to present them to the President of e Senate and the Speaker of the Assembly.

The Council of the New York Academy of Medicine adopted, on April 26, e following resolution: "*Resolved*, That the members of this Council, know-g the filthy streets to be an active cause of disease, and that those of the city New York are in a disgracefully dirty condition, respectfully urge upon the egislature of the State of New York, as an efficient means of relief, the pas-ge of the bill in reference to street cleaning known as the 'Citizens' Bill,' now efore the Conference Committees."

—

New York Stenches.—The Committee of the State Board of Health on the ench nuisances at Hunter's Point, Brooklyn, having reported that the com-laints in regard to the noisome odours were well founded, and having indicated

as the source of the offensive emanations the various factories mentioned in the April No. of THE MEDICAL NEWS AND ABSTRACT, the State Board forwarded an abstract of the report to Governor Cornell. A proclamation was immediately made by the Governor, directing the owners of all the factories designated as sources of offensive effluvia to take measures for the abatement or prevention of the latter before June 1, 1881. In the event of failure on the part of the factory proprietors to comply with this regulation, the district attorneys of Kings and Queens Counties will be directed by the Governor to bring action against the offenders. Authority for this action is furnished by a law passed in 1880 (8th sec. of the 322d chapter of Laws of 1880).

—

The Visiting Staff of Bellevue Hospital.—Dr. T. T. Sabine has resigned his position as visiting surgeon to Bellevue Hospital, and Dr. Chas. McBurney has been appointed his successor.

—

A Night Medical Service in Brooklyn.—Governor Cornell has signed the bill for the establishment of a night medical service in Brooklyn.

—

College of Physicians and Surgeons, New York.—At the annual commencement of the medical department of Columbia College, held on May 13, 120 graduates received their diplomas. A social meeting of the alumni of the college was held in the evening at Delmonico's.

—

Meetings of State Medical Societies:—

Connecticut State Medical Society meets at Hartford, June 22.

Massachusetts Medical Society meets at Boston, June 7.

Michigan State Medical Society meets at Bay City, June 8.

New Hampshire Medical Society meets at Concord, June 21.

Ohio State Medical Society meets at Columbus, June 14.

Wisconsin State Medical Society meets at Milwaukee, June 7.

On the 7th and 8th of June the Massachusetts Society will celebrate their Centennial Anniversary with proper honours, and addresses will be delivered by Drs. Samuel A. Green and J. Collins Warren, of Boston.

—

OBITUARY RECORD.—At Berlin, on the 21st of April, after a short illness, Dr. LUDWIG WALDENBURG, in the forty-third year of his age. Dr. Waldenburg was professor in the University of Berlin, physician to the Charité Hospital, and editor of the *Berliner Klinische Wochenschrift*. He devoted his attention chiefly to diseases of the respiratory organs, on which he has written a comprehensive treatise, and was the inventor of an apparatus for the inspiration of compressed air, which has been much used. Dr. Waldenburg exercised great influence throughout the medical profession in Germany in his position as the acknowledged editor of its most influential medical journal. The *Berliner Klinische Wochenschrift* was always well edited, contained valuable scientific matter, and had an useful influence on those social and political questions in which the medical profession is constantly called upon to pronounce an opinion, and to direct public opinion, and frequently to prepare the way for necessary legislation. His independent character and his discretion lent force to his advocacy, and gave great weight to his judgments.—*British Med. Journal*, April 23, 1881.

——— At New York, on April 30th, aged 58, SALVATORE CARO, M.D., a physician of recognized ability and very enviable reputation. Dr. Caro graduated at the University of Palermo, in 1848, and came to this country in 1852.

HENRY C. LEA'S SON & CO.'S

(LATE HENRY C. LEA)

CLASSIFIED CATALOGUE

OF

MEDICAL AND SURGICAL PUBLICATIONS.

n asking the attention of the profession to the works advertised in the following es, the publishers would state that no pains are spared to secure a continuance of confidence earned for the publications of the house by their careful selection and uracy and finish of execution.

The large number of inquiries received from the profession for a finer class of bind- than is usually placed on medical books has induced us to put certain of our dard publications in half Russia, and that the growing taste may be encouraged, prices have been fixed at so small an advance over the cost of sheep, as to place it in the means of all to possess a library that shall have attractions as well for the as for the mind of the reading practitioner.

he printed prices are those at which books can generally be supplied by book- rs throughout the United States, who can readily procure for their customers any ks not kept in stock. Where access to bookstores is not convenient, books will be by mail post-paid on receipt of the price, and as the limit of mailable weight has removed, no difficulty will be experienced in obtaining through the post-office work in this catalogue. No risks, however, are assumed either on the money or he books, and no publications but our own are supplied, so that gentlemen will in cases find it more convenient to deal with the nearest bookseller.

HENRY C. LEA'S SON & CO.

s. 706 and 708 SANSOM ST., PHILADELPHIA, April, 1881.

INCREASED INDUCEMENT FOR SUBSCRIBERS TO

E AMERICAN JOURNAL OF THE MEDICAL SCIENCES.

TWO MEDICAL JOURNALS, containing nearly 2000 LARGE PAGES,

Free of Postage, for FIVE DOLLARS Per Annum.

TERMS FOR 1881.

AMERICAN JOURNAL OF THE MEDICAL SCIENCES, published quarterly (1150 pages per annum), with MEDICAL NEWS AND ABSTRACT, monthly (768 pp. per annum), } Five Dollars per annum, in advance.

SEPARATE SUBSCRIPTIONS TO

IE AMERICAN JOURNAL OF THE MEDICAL SCIENCES, when not paid for in advance, Five Dollars.

IE MEDICAL NEWS AND ABSTRACT, free of postage, in advance, Two Dollars and a half.

* Advance paying subscribers can obtain at the close of the year cloth covers, ettered, for each volume of the Journal (two annually), and of the News and ract (one annually), free by mail, by remitting ten cents for each cover.

---

will thus be seen that for the moderate sum of FIVE DOLLARS in advance, the riber will receive, free of postage, the equivalent of four large octavo volumes, d with the choicest matter, original and selected, that can be furnished by the cal literature of both hemispheres. Thus taken together, the "JOURNAL" and 'NEWS AND ABSTRACT" combine the advantages of the elaborate preparation can be devoted to the Quarterly with the prompt conveyance of intelligence by Monthly; while, the whole being under a single editorial supervision, the sub- er is secured against the duplication of matter inevitable when periodicals from rent sources are taken together.

e periodicals thus offered at this unprecedented rate are universally known for

their high professional standing.

I.

THE AMERICAN JOURNAL OF THE MEDICAL SCIENCES,

EDITED BY I. MINIS HAYS, M.D.,

for more than half a century has maintained its position in the front rank of the medical literature of the world. Cordially supported by the profession of America, it circulates wherever the language is read, and is universally regarded as the national exponent of American medicine—a position to which it is entitled by the distinguished names from every section of the Union which are to be found among its collaborators.* It is issued quarterly, in January, April, July, and October, each number containing about three hundred octavo pages, appropriately illustrated wherever necessary. A large portion of this space is devoted to Original Communications, embracing papers from the most eminent members of the profession throughout the country.

Following this is the REVIEW DEPARTMENT, containing extended reviews by competent writers of prominent new works and topics of the day, together with numerous elaborate Analytical and Bibliographical Notices, giving a fairly complete survey of medical literature.

Then follows the QUARTERLY SUMMARY OF IMPROVEMENTS AND DISCOVERIES IN THE MEDICAL SCIENCES, classified and arranged under different heads, and furnishing a digest of medical progress, abroad and at home.

Thus during the year 1880 the "JOURNAL" contained 67 Original Communications, mostly elaborate in character, 170 Reviews and Bibliographical Notices, and 147 articles in the Quarterly Summaries, illustrated with 47 wood engravings.

That the efforts thus made to maintain the high reputation of the "JOURNAL" are successful, is shown by the position accorded to it in both America and Europe as the leading organ of medical progress:—

This is universally acknowledged as the leading American Journal, and has been conducted by Dr. Hays alone until 1869, when his son was associated with him. We quite agree with the critic, that this journal is second to none in the language, and cheerfully accord to it the first place, for nowhere shall we find more able and more impartial criticism, and nowhere such a repertory of able original articles. Indeed, now that the "British and Foreign Medico-Chirurgical Review" has terminated its career, the American Journal stands without a rival.—*London Med. Times and Gazette*, Nov. 24, 1877.

The best medical journal on the continent.—*Boston Med. and Surg. Journal*, April, 1879.

The present number of the American Journal is an exceedingly good one, and gives every promise of maintaining the well-earned reputation of the review. Our venerable contemporary has our best wishes, and we can only express the hope that it may continue its work with as much vigor and excellence for the next fifty years as it has exhibited in the past.—*London Lancet*, Nov. 24, 1877.

The Philadelphia Medical and Physical Journal issued its first number in 1820, and, after a brilliant career, was succeeded in 1827 by the American Journal of the Medical Sciences, a periodical of world-wide reputation; the ablest and one of the oldest periodicals in the world—a journal which has an unsullied record.—*Gross's History of American Med. Literature* 1876.

The best medical journal ever published in Europe or America.—*Va. Med. Monthly*, May, 1879.

It is universally acknowledged to be the leading American medical journal, and, in our opinion, is second to none in the language.—*Boston Med. and Surg. Journal*, Oct. 1877.

This is the medical journal of our country to which the American physician abroad will point with the greatest satisfaction, as reflecting the state of medical culture in his country. For a great many years it has been the medium through which our ablest writers have made known their discoveries and observations.—*Address of L. P. Yandell, M.D., before International Med. Congress*, Sept. 1876.

And that it was specifically included in the award of a medal of merit to the Publishers in the Vienna Exhibition in 1873.

The subscription price of the "AMERICAN JOURNAL OF THE MEDICAL SCIENCES" has never been raised during its long career. It is still FIVE DOLLARS per annum; and when paid for in advance, the subscriber receives in addition the "MEDICAL NEWS AND ABSTRACT," making in all nearly 2000 large octavo pages per annum, free of postage.

II.

THE MEDICAL NEWS AND ABSTRACT.

Thirty-eight years ago the "MEDICAL NEWS" was commenced as a monthly to convey to the subscribers of the "AMERICAN JOURNAL" the clinical instruction and

* Communications are invited from gentlemen in all parts of the country. Articles inserted by the Editor are liberally paid for by the publishers.

rrent information which could not be accommodated in the Quarterly. It consisted sixteen pages of such matter, together with sixteen more known as the Library epartment and devoted to the publishing of books. With the increased progress of ience, however, this was found insufficient, and some years since another periodical, own as the "MONTHLY ABSTRACT," was started, and was furnished at a moderate ice to subscribers to the "AMERICAN JOURNAL." These two monthlies have been nsolidated, under the title of "THE MEDICAL NEWS AND ABSTRACT," and are rnished *free of charge* in connection with the "AMERICAN JOURNAL."

The "NEWS AND ABSTRACT" consists of 64 pages monthly, in a neat cover. It ntains a CLINICAL DEPARTMENT in which will be continued the series of ORIGINAL MERICAN CLINICAL LECTURES, by gentlemen of the highest reputation through- the United States, together with a choice selection of foreign Lectures and spital Notes and Gleanings. Then follows the MONTHLY ABSTRACT, systemati- ly arranged and classified, and presenting five or six hundred articles yearly; and ch number concludes with an EDITORIAL and a NEWS DEPARTMENT, giving cur- t professional intelligence, domestic and foreign, the whole fully indexed at the close each volume, rendering it of permanent value for reference.

As stated above, the subscription price to the "NEWS AND ABSTRACT" is Two llars and a Half per annum, invariably in advance, at which rate it ranks as one the cheapest medical periodicals in the country. But it is also furnished, free of charge, in commutation with the "AMERICAN JOURNAL OF THE MEDICAL IENCES," to all who remit FIVE DOLLARS in advance, thus giving to the subscriber, that very moderate sum, a complete record of medical progress throughout the rld, in the compass of about two thousand large octavo pages.

n this effort to furnish so large an amount of practical information at a price so un- ecedentedly low, and thus place it within the reach of every member of the profes- , the publishers confidently anticipate the friendly aid of all who feel an interest in dissemination of sound medical literature. They trust, especially, that the sub- bers to the "AMERICAN MEDICAL JOURNAL," will call the attention of their uaintances to the advantages thus offered, and that they will be sustained in the eavor to permanently establish medical periodical literature on a footing of cheap- s never heretofore attempted.

REMIUM FOR OBTAINING NEW SUBSCRIBERS TO THE "JOURNAL."

ny gentleman who will remit the amount for two subscriptions for 1881, one of ch at least must be for a *new subscriber*, will receive as a PREMIUM, free by mail, py of any one of the following recent works:—

"SEILER ON THE THROAT" (see p. 19),
"BARNES'S MANUAL OF MIDWIFERY" (see p. 25),
"TILBURY FOX'S EPITOME OF DISEASES OF THE SKIN," new edition (see p. 18),
"HOLDEN'S LANDMARKS, MEDICAL AND SURGICAL" (see p. 6),
"BROWNE ON THE USE OF THE OPHTHALMOSCOPE" (see p. 29),
"FLINT'S ESSAYS ON CONSERVATIVE MEDICINE" (see p. 15),
"STURGES'S CLINICAL MEDICINE" (see p. 15),
"SWAYNE'S OBSTETRIC APHORISMS," new edition (see p. 21),
"TANNER'S CLINICAL MANUAL" (see p. 5),
"WEST ON NERVOUS DISORDERS OF CHILDREN" (see p. 20).

* Gentlemen desiring to avail themselves of the advantages thus offered will do to forward their subscriptions at an early day, in order to insure the receipt of plete sets for the year 1881.

☞ The safest mode of remittance is by bank check or postal money order, drawn he order of the undersigned. Where these are not accessible, remittances for the OURNAL" may be made at the risk of the publishers, by forwarding in REGISTERED ers. Address,

HENRY C. LEA'S SON & CO., Nos. 706 and 708 Sansom St., Phila., Pa.

DUNGLISON (*ROBLEY*), *M.D.*,

Late Professor of Institutes of Medicine in Jefferson Medical College, Philadelphia.

MEDICAL LEXICON; A DICTIONARY OF MEDICAL SCIENCE:

Containing a concise explanation of the various Subjects and Terms of Anatomy, Physiology, Pathology, Hygiene, Therapeutics, Pharmacology, Pharmacy, Surgery, Obstetrics, Medical Jurisprudence, and Dentistry. Notices of Climate and of Mineral Waters; Formulæ for Officinal, Empirical, and Dietetic Preparations; with the Accentuation and Etymology of the Terms, and the French and other Synonymes; so as to constitute a French as well as English Medical Lexicon. A New Edition. Thoroughly Revised, and very greatly Modified and Augmented. By RICHARD J. DUNGLISON, M.D. In one very large and handsome royal octavo volume of over 1100 pages. Cloth, $6 50; leather, raised bands, $7 50; half Russia, $8. (*Just Issued.*)

The object of the author from the outset has not been to make the work a mere lexicon or dictionary of terms, but to afford, under each, a condensed view of its various medical relations, and thus to render the work an epitome of the existing condition of medical science. Starting with this view, the immense demand which has existed for the work has enabled him, in repeated revisions, to augment its completeness and usefulness, until at length it has attained the position of a recognised and standard authority wherever the language is spoken.

Special pains have been taken in the preparation of the present edition to maintain this enviable reputation. During the ten years which have elapsed since the last revision, the additions to the nomenclature of the medical sciences have been greater than perhaps in any similar period of the past, and up to the time of his death the author labored assiduously to incorporate everything requiring the attention of the student or practitioner. Since then, the editor has been equally industrious, so that the additions to the vocabulary are more numerous than in any previous revision. Especial attention has been bestowed on the accentuation, which will be found marked on every word. The typographical arrangement has been much improved, rendering reference much more easy, and every care has been taken with the mechanical execution. The work has been printed on new type, small but exceedingly clear, with an enlarged page, so that the additions have been incorporated with an increase of but little over a hundred pages, and the volume now contains the matter of at least four ordinary octavos.

A book well known to our readers, and of which every American ought to be proud. When the learned author of the work passed away, probably all of us feared lest the book should not maintain its place in the advancing science whose terms it defines. Fortunately, Dr. Richard J. Dunglison, having assisted his father in the revision of several editions of the work, and having been, therefore, trained in the methods and imbued with the spirit of the book, has been able to edit it, not in the patchwork manner so dear to the heart of book editors, so repulsive to the taste of intelligent book readers, but to edit it as a work of the kind should be edited—to carry it on steadily, without jar or interruption, along the grooves of thought it has travelled during its lifetime. To show the magnitude of the task which Dr. Dunglison has assumed and carried through, it is only necessary to state that more than six thousand new subjects have been added in the present edition.—*Phila. Med. Times*, Jan. 3, 1874.

About the first book purchased by the medical student is the Medical Dictionary. The lexicon explanatory of technical terms is simply a *sine qua non*. In a science so extensive, and with such collaterals as medicine, it is as much a necessity also to the practising physician. To meet the wants of students and most physicians, the dictionary must be condensed while comprehensive, and practical while perspicacious. It was because Dunglison's met these indications that it became at once the dictionary of general use wherever medicine was studied in the English language. In no former revision have the alterations and additions been so great. More than six thousand new subjects and terms have been added. The chief terms have been set in black letter, while the derivatives follow in small caps; an arrangement which greatly facilitates reference. We may safely confirm the hope ventured by the editor "that the work, which possesses for him a filial as well as an individual interest, will be found worthy a continuance of the position so long accorded to it as a standard authority."—*Cincinnati Clinic*, Jan. 10, 1874.

It has the rare merit that it certainly has no rival in the English language for accuracy and extent of references.—*London Medical Gazette*.

As a standard work of reference, as one of the best, if not the very best, medical dictionary in the English language, Dunglison's work has been well known for about forty years, and needs no words of praise on our part to recommend it to the members of the medical, and, likewise, of the pharmaceutical profession. The latter especially are in need of such a work, which gives ready and reliable information on thousands of subjects and terms which they are liable to encounter in pursuing their daily avocations, but with which they cannot be expected to be familiar. The work before us fully supplies this want.—*Am. Journ. of Pharm.*, Feb. 1874.

A valuable dictionary of the terms employed in medicine and the allied sciences, and of the relations of the subjects treated under each head. It reflects great credit on its able American author, and well deserves the authority and popularity it has obtained.—*British Med. Journ.*, Oct. 31, 1874.

Few works of this class exhibit a grander monument of patient research and of scientific lore. The extent of the sale of this lexicon is sufficient to testify to its usefulness, and to the great service conferred by Dr. Robley Dunglison on the profession, and indeed on others, by its issue.—*London Lancet*, May 13, 1875.

HOBLYN (*RICHARD D.*), *M.D*

A DICTIONARY OF THE TERMS USED IN MEDICINE AND THE COLLATERAL SCIENCES.

Revised, with numerous additions, by ISAAC HAYS, M. D., Editor of the "American Journal of the Medical Sciences." In one large royal 12mo. volume of over 500 double-columned pages; cloth, $1 50; leather, $2 00

It is the best book of definitions we have, and ought always to be upon the student's table.—*Southern Med. and Surg Journal.*

RODWELL (*G. F.*), *F.R.A.S.*, *&c.*

A DICTIONARY OF SCIENCE: Comprising Astronomy, Chemistry, Dynamics, Electricity, Heat, Hydrodynamics, Hydrostatics, Light, Magnetism, Mechanics, Meteorology, Pneumatics, Sound, and Statics, Preceded by an Essay on the History of the Physical Sciences. In one handsome octavo volume of 694 pages. with many illustrations: cloth, $5.

A *CENTURY OF AMERICAN MEDICINE*, 1776–1876. By Doctors E. H. Clarke, H. J. Bigelow, S. D. Gross, T. G. Thomas, and J. S. Billings. In one very handsome 12mo. volume of about 350 pages: cloth, $2 25. (*Lately Issued.*)

This work appeared in the pages of the American Journal of the Medical Sciences during the ear 1876. As a detailed account of the development of medical science in America, by gentlemen of the highest authority in their respective departments, the profession will no doubt welome it in a form adapted for preservation and reference.

NEILL (*JOHN*), *M.D.*, *and* *SMITH* (*FRANCIS G.*), *M.D.*,
Prof. of the Institutes of Medicine in the Univ. of Penna.

AN ANALYTICAL COMPENDIUM OF THE VARIOUS BRANCHES OF MEDICAL SCIENCE; for the Use and Examination of Students. A new edition, revised and improved. In one very large and handsomely printed royal 12mo. volume, of about one thousand pages, with 374 wood-cuts, cloth, $4; strongly bound in leather, with raised bands, $4 75.

HARTSHORNE (*HENRY*), *M.D.*,
Professor of Hygiene in the University of Pennsylvania.

A CONSPECTUS OF THE MEDICAL SCIENCES; containing Handbooks on Anatomy, Physiology, Chemistry, Materia Medica, Practical Medicine, Surgery, and Obstetrics. Second Edition, thoroughly revised and improved. In one large royal 12mo. volume of more than 1000 closely printed pages, with 477 illustrations on wood. Cloth, $4 25; leather, $5 00. (*Lately Issued.*)

We can say with the strictest truth that it is the st work of the kind with which we are acquainted. mbodies in a condensed form all recent contribuns to practical medicine, and is therefore useful every busy practitioner throughout our country, vides admirably adapted to the use of stuts of medicine. The book is faithfully and ably cuted.—*Charleston Med. Journ.*, April, 1875

The work is intended as an aid to the medical dent, and as such appears to admirably fulfil its ject by its excellent arrangement, the full compidon of facts, the perspicuity and terseness of lanage, and the clear and instructive illustrations some parts of the work.—*American Journ. of rmacy*, Philadelphia, July, 1874.

The volume will be found useful, not only to stuts, but to many others who may desire to refresh ir memories with the smallest possible expenditre of time.—*N. Y. Med. Journal*, Sept. 1874.

The student will find this the most convenient and eful book of the kind on which he can lay his nd.—*Pacific Med. and Surg. Journ.*, Aug. 1874.

This is the best book of its kind that we have ever amined. It is an honest, accurate, and concise mpend of medical sciences, as fairly as possible resenting their present condition. The changes d the additions have been so judicious and thogh as to render it, so far as it goes, entirely trustworthy. If students must have a conspectus, they will be wise to procure that of Dr. Hartshorne.—*Detroit Rev. of Med. and Pharm.*, Aug. 1874.

The work before us has many redeeming features not possessed by others, and is the best we have seen. Dr. Hartshorne exhibits much skill in condensation. It is well adapted to the physician in active practice, who can give but limited time to the familiarizing of himself with the important changes which have been made since he attended lectures. The manual of physiology has also been improved and gives the most comprehensive view of the latest advances in the science possible in the space devoted to the subject. The mechanical execution of the book leaves nothing to be wished for.—*Peninsular Journal of Medicine*, Sept. 1874.

After carefully looking through this conspectus, we are constrained to say that it is the most complete work, especially in its illustrations, of its kind that we have seen.—*Cincinnati Lancet*, Sept. 1874.

The favor with which the first edition of this Compendium was received, was an evidence of its various excellences. The present edition bears evidence of a careful and thorough revision. Dr. Hartshorne possesses a happy faculty of seizing upon the salient points of each subject, and of presenting them in a concise and yet perspicuous manner.—*Leavenworth Med. Herald*, Oct. 1874

LUDLOW (*J. L.*), *M.D.*

A MANUAL OF EXAMINATIONS upon Anatomy, Physiology, Surgery, Practice of Medicine, Obstetrics, Materia Medica, Chemistry, Pharmacy, and Therapeutics. To which is added a Medical Formulary. Third edition, thoroughly revised and greatly extended and enlarged. With 370 illustrations. In one handsome royal 12mo. volume of 816 large pages. Cloth, $3 25; leather, $3 75.

The arrangement of this volume in the form of question and answer renders it especially suitle for the office examination of students, and for those preparing for graduation.

TANNER (*THOMAS HAWKES*), *M.D.*, *&c.*

A MANUAL OF CLINICAL MEDICINE AND PHYSICAL DIAGNOSIS. Third American from the Second London Edition. Revised and Enlarged by TILBURY FOX, M. D., Physician to the Skin Department in University College Hospital, London, &c. In one neat volume small 12mo., of about 375 pages, cloth, $1 50.

*** On page 3, it will be seen that this work is offered as a premium for procuring new bscribers to the "AMERICAN JOURNAL OF THE MEDICAL SCIENCES."

GRAY (HENRY), F.R.S.,

Lecturer on Anatomy at St. George's Hospital, London.

ANATOMY, DESCRIPTIVE AND SURGICAL. The Drawings by H. V. CARTER, M.D., and Dr. WESTMACOTT. The Dissections jointly by the AUTHOR and Dr. CARTER. With an Introduction on General Anatomy and Development by T. HOLMES, M.A., Surgeon to St. George's Hospital. A new American, from the Eighth enlarged and improved London edition. To which is added "LANDMARKS, MEDICAL AND SURGICAL," by LUTHER HOLDEN, F.R.C.S., author of "Human Osteology," "A Manual of Dissections," etc. In one magnificent imperial octavo volume of 983 pages, with 522 large and elaborate engravings on wood. Cloth, $6; leather, raised bands, $7; half Russia, $7 50. (*Now Ready.*)

The author has endeavored in this work to cover a more extended range of subjects than is customary in the ordinary text-books, by giving not only the details necessary for the student, but also the application of those details in the practice of medicine and surgery, thus rendering it both a guide for the learner, and an admirable work of reference for the active practitioner. The engravings form a special feature in the work, many of them being the size of nature, nearly all original, and having the names of the various parts printed on the body of the cut, in place of figures of reference, with descriptions at the foot. They thus form a complete and splendid series, which will greatly assist the student in obtaining a clear idea of Anatomy, and will also serve to refresh the memory of those who may find in the exigencies of practice the necessity of recalling the details of the dissecting room; while combining, as it does, a complete Atlas of Anatomy, with a thorough treatise on systematic, descriptive, and applied Anatomy, the work will be found of essential use to all physicians who receive students in their offices, relieving both preceptor and pupil of much labor in laying the groundwork of a thorough medical education.

Since the appearance of the last American Edition, the work has received three revisions at the hands of its accomplished editor, Mr. Holmes, who has sedulously introduced whatever has seemed requisite to maintain its reputation as a complete and authoritative standard text-book and work of reference. Still further to increase its usefulness, there has been appended to it the recent work by the distinguished anatomist, Mr. Luther Holden—"Landmarks, Medical and Surgical"—which gives in a clear, condensed and systematic way, all the information by which the practitioner can determine from the external surface of the body the position of internal parts. Thus complete, the work, it is believed, will furnish all the assistance that can be rendered by type and illustration in anatomical study. No pains have been spared in the typographical execution of the volume, which will be found in all respects superior to former issues. Notwithstanding the increase of size, amounting to over 100 pages and 57 illustrations, it will be kept, as heretofore, at a price rendering it one of the cheapest works ever offered to the American profession.

The recent work of Mr. Holden, which was noticed by us on p. 53 of this volume, has been added as an appendix, so that, altogether, this is the most practical and complete anatomical treatise available to American students and physicians. The former finds in it the necessary guide in making dissections; a very comprehensive chapter on minute anatomy; and about all that can be taught him on general and special anatomy; while the latter, in its treatment of each region from a surgical point of view, and in the valuable addition of Mr. Holden, will find all that will be essential to him in his practice.—*New Remedies*, Aug. 1878.

This work is as near perfection as one could possibly or reasonably expect any book intended as a text-book or a general reference book on anatomy to be. The American publisher deserves the thanks of the profession for appending the recent work of Mr. Holden, "*Landmarks, Medical and Surgical*," which has already been commended as a separate book. The latter work—treating of topographical anatomy—has become an essential to the library of every intelligent practitioner. We know of no book that can take its place, written as it is by a most distinguished anatomist. It would be simply a waste of words to say anything further in praise of Gray's Anatomy, the text-book in almost every medical college in this country, and the daily reference book of every practitioner who has occasion to consult his books on anatomy. The work is simply indispensable, especially this present American edition.—*Va. Med. Monthly*, Sept. 1878.

The addition of the recent work of Mr. Holden, as an appendix, renders this the most practical and complete treatise available to American students, who find in it a comprehensive chapter on minute anatomy, about all that can be taught on general and special anatomy, while its treatment of each region, from a surgical point of view, in the valuable section by Mr Holden, is all that will be essential to them in practice.—*Ohio Medical Recorder*, Aug 1878.

It is difficult to speak in moderate terms of this new edition of "Gray." It seems to be as nearly perfect as it is possible to make a book devoted to any branch of medical science. The labors of the eminent men who have successively revised the eight editions through which it has passed, would seem to leave nothing for future editors to do. The addition of Holden's "Landmarks" will make it an indispensable to the practitioner of medicine and surgery as it has been heretofore to the student. As regards completeness, ease of reference, utility, beauty, and cheapness, it has no rival. No student should enter a medical school without it; no physician can afford to have it absent from his library.—*St. Louis Clin. Record*, Sept. 1878.

ALSO FOR SALE SEPARATE—

HOLDEN (LUTHER), F.R.C.S.,

Surgeon to St. Bartholomew's and the Foundling Hospitals.

LANDMARKS, MEDICAL AND SURGICAL. From the 2d London Ed. In one handsome volume, royal 12mo., of 128 pages. Cloth, 88 cents. (*Now Ready.*)

HEATH (CHRISTOPHER), F.R.C.S.,

Teacher of Operative Surgery in University College, London.

PRACTICAL ANATOMY: A Manual of Dissections. From the Second revised and improved London edition. Edited, with additions, by W. W. KEEN, M. D., Lecturer on Pathological Anatomy in the Jefferson Medical College, Philadelphia. In one handsome royal 12mo. volume of 578 pages, with 247 illustrations. Cloth, $3 50; leather, $4 00.

ALLEN (HARRISON), M.D.
Professor of Physiology in the Univ. of Pa.

A SYSTEM OF HUMAN ANATOMY: INCLUDING ITS MEDICAL and Surgical Relations. For the Use of Practitioners and Students of Medicine. With an Introductory Chapter on Histology. By E. O. SHAKESPEARE, M.D., Ophthalmologist to the Phila. Hosp. In one large and handsome quarto volume, with several hundred original illustrations on lithographic plates, and numerous wood-cuts in the text. (*Shortly.*)

In this elaborate work, which has been in active preparation for several years, the author has sought to give, not only the details of descriptive anatomy in a clear and condensed form, but also the practical applications of the science to medicine and surgery. The work thus has claims upon the attention of the general practitioner, as well as of the student, enabling him not only to refresh his recollections of the dissecting room, but also to recognize the significance of all variations from normal conditions. The marked utility of the object thus sought by the author is self-evident, and his long experience and assiduous devotion to its thorough development are a sufficient guarantee of the manner in which his aims have been carried out. No pains have been spared with the illustrations. Those of normal anatomy are from original dissections, drawn on stone by Mr. Hermann Faber, with the name of every part clearly engraved upon the figure, after the manner of "Holden" and "Gray," and in every typographical detail it will be the effort of the publishers to render the volume worthy of the very distinguished position which is anticipated for it.

ELLIS (GEORGE VINER).
Emeritus Professor of Anatomy in University College, London.

DEMONSTRATIONS OF ANATOMY; Being a Guide to the Knowledge of the Human Body by Dissection. By GEORGE VINER ELLIS, Emeritus Professor of Anatomy in University College, London. From the Eighth and Revised London Edition. In one very handsome octavo volume of over 700 pages, with 256 illustrations. Cloth, $4.25; leather, $5.25. (*Now Ready.*)

This work has long been known in England as the leading authority on practical anatomy, and the favorite guide in the dissecting-room, as is attested by the numerous editions through which it has passed. In the last revision, which has just appeared in London, the accomplished author has sought to bring it on a level with the most recent advances of science by making the necessary changes in his account of the microscopic structure of the different organs, as developed by the latest researches in textural anatomy.

Ellis's Demonstrations is the favorite text-book of the English student of anatomy. In passing through eight editions it has been so revised and adapted to the needs of the student that it would seem that it had almost reached perfection in this special line. The descriptions are clear, and the methods of pursuing anatomical investigations are given with such detail that the book is honestly entitled to its name.—*St. Louis Clinical Record*, June, 1879.

The success of this old manual seems to be as well deserved in the present as in the past volumes. The book seems destined to maintain yet for years its leadership over the English manuals upon dissecting.—*Phila. Med. Times*, May 24, 1879.

As a dissector, or a work to have in hand and studied while one is engaged in dissecting, we regard it as the very best work extant, which is certainly saying a very great deal. As a text-book to be studied in the dissecting-room, it is superior to any of the works upon anatomy.—*Cincinnati Med. News*, May 24, 1879.

We most unreservedly recommend it to every practitioner of medicine who can possibly get it.—*Va. Med. Monthly*, June, 1879.

WILSON (ERASMUS), F.R.S.

A SYSTEM OF HUMAN ANATOMY, General and Special. Edited by W. H. GOBRECHT, M.D., Professor of General and Surgical Anatomy in the Medical College of Ohio. Illustrated with three hundred and ninety-seven engravings on wood. In one large and handsome octavo volume, of over 600 pages; cloth, $4; leather, $5.

SMITH (HENRY H.), M.D., and HORNER (WILLIAM E.), M.D.,
Prof. of Surgery in the Univ. of Penna., &c. *Late Prof. of Anatomy in the Univ. of Penna.*

AN ANATOMICAL ATLAS; Illustrative of the Structure of the Human Body. In one volume, large imperial octavo, cloth, with about six hundred and fifty beautiful figures. $4 50.

SCHÄFER (EDWARD ALBERT), M.D.,
Assistant Professor of Physiology in University College, London.

A COURSE OF PRACTICAL HISTOLOGY: Being an Introduction to the Use of the Microscope. In one handsome royal 12mo. volume of 304 pages, with numerous illustrations: cloth, $2 00. (*Just Issued.*)

HORNER'S SPECIAL ANATOMY AND HISTOLOGY. Eighth edition, extensively revised and modified. In 2 vols. 8vo., of over 1000 pages, with 320 wood-cuts: cloth, $6 00.

HARPEY AND QUAIN'S HUMAN ANATOMY. Revised, by JOSEPH LEIDY, M.D., Prof of Anat. in Univ. of Penn. In two octavo vols. of about 1300 pages, with 511 illustrations Cloth, $6 00.

BELLAMY'S STUDENT'S GUIDE TO SURGICAL ANATOMY: A Text-book for Students prepa ing for their Pass Examination. With engravings on wood In one handsome royal 12mo. volume. Cloth, $2 25.

CLELAND'S DIRECTORY FOR THE DISSECTION OF THE HUMAN BODY. In one small volume, royal 12mo. of 182 pages: cloth $1 25.

HARTSHORNE'S HANDBOOK OF ANATOMY AND PHYSIOLOGY. Second edition, revised. In one royal 12mo. vol., with 220 wood cuts; cloth, $1 75.

DALTON (J. C.), M.D.,

Professor of Physiology in the College of Physicians and Surgeons, New York, &c.

A TREATISE ON HUMAN PHYSIOLOGY. Designed for the use of Students and Practitioners of Medicine. Sixth edition, thoroughly revised and enlarged, with three hundred and sixteen illustrations on wood. In one very beautiful octavo volume, of over 800 pages. Cloth, $5 50; leather, $6 50; half Russia, $7. (*Lately Issued.*)

During the past few years several new works on physiology, and new editions of old works, have appeared, competing for the favor of the medical student, but none will rival this new edition of Dalton. As now enlarged, it will be found also to be, in general, a satisfactory work of reference for the practitioner.—*Chicago Med. Journ. and Examiner*, Jan. 1876.

Prof. Dalton has discussed conflicting theories and conclusions regarding physiological questions with a fairness, a fulness, and a conciseness which lend freshness and vigor to the entire book. But his discussions have been so guarded by a refusal of admission to those speculative and theoretical explanations, which at best exist in the minds of observers themselves as only probabilities, that none of his readers need be led into grave errors while making them a study.—*The Medical Record*, Feb. 19, 1876.

The revision of this great work has brought it forward with the physiological advances of the day, and renders it, as it has ever been, the finest work for students extant.—*Nashville Journ. of Med. and Surg.*, Jan. 1876.

For clearness and perspicuity, Dalton's Physiology commended itself to the student years ago, and was a pleasant relief from the verbose productions which it supplanted. Physiology has, however, made many advances since then—and while the style has been preserved intact, the work in the present edition has been brought up fully abreast of the times. The new chemical notation and nomenclature have also been introduced into the present edition. Notwithstanding the multiplicity of text-books on physiology, this will lose none of its old time popularity. The mechanical execution of the work is all that could be desired.—*Peninsular Journal of Medicine*, Dec. 1875.

This popular text-book on physiology comes to us in its sixth edition with the addition of about fifty per cent. of new matter, chiefly in the departments of pathological chemistry and the nervous system, where the principal advances have been realized. With so thorough revision and additions, that keep the work well up to the times, its continued popularity may be confidently predicted, notwithstanding the competition it may encounter. The publisher's work is admirably done.—*St. Louis Med. and Surg. Journ.*, Dec. 1875.

We heartily welcome this, the sixth edition of this admirable text-book, than which there are none of equal brevity more valuable. It is cordially recommended by the Professor of Physiology in the University of Louisiana, as by all competent teachers in the United States, and wherever the English language is read, this book has been appreciated. The present edition, with its 316 admirably executed illustrations, has been carefully revised and very much enlarged, although its bulk does not seem perceptibly increased.—*New Orleans Medical and Surgical Journal*, March, 1876.

CARPENTER (WILLIAM B.), M. D., F. R. S., F.G.S., F.L.S.,

Registrar to University of London, &c.

PRINCIPLES OF HUMAN PHYSIOLOGY; Edited by HENRY POWER, M.B. Lond., F.R.C.S., Examiner in Natural Sciences, University of Oxford. A new American from the Eighth Revised and Enlarged English Edition, with Notes and Additions, by FRANCIS G. SMITH, M.D., Professor of the Institutes of Medicine in the University of Pennsylvania, etc. In one very large and handsome octavo volume, of 1083 pages, with two plates and 373 engravings on wood. Cloth, $5 50; leather, $6 50; half Russia, $7. (*Just Issued.*)

We have been agreeably surprised to find the volume so complete in regard to the structure and functions of the nervous system in all its relations, a subject that, in many respects, is one of the most difficult of all, in the whole range of physiology, upon which to produce a full and satisfactory treatise of the class to which the one before us belongs. The additions by the American editor give to the work as it is a considerable value beyond that of the last English edition. In conclusion, we can give our cordial recommendation to the work as it now appears. The editors have, with their additions to the only work on physiology in our language that, in the fullest sense of the word, is the production of a philosopher as well as a physiologist, brought it up as fully as could be expected, if not desired, to the standard of our knowledge of its subject at the present day. It will deservedly maintain the place it has always had in the favor of the medical profession.—*Journ. of Nervous and Mental Disease*, April, 1877.

Such enormous advances have recently been made in our physiological knowledge, that what was perfectly new a year or two ago, looks now as if it had been a received and established fact for years. In this encyclopædic way it is unrivalled. Here, as it seems to us, is the great value of the book: one is safe in sending a student to it for information on almost any given subject, perfectly certain of the fulness of information it will convey, and well satisfied of the accuracy with which it will there be found stated.—*London Med. Times and Gazette*, Feb. 17, 1877.

The merits of "Carpenter's Physiology" are so widely known and appreciated that we need only allude briefly to the fact that in the latest edition will be found a comprehensive embodiment of the results of recent physiological investigation. Care has been taken to preserve the practical character of the original work. In fact the entire work has been brought up to date, and bears evidence of the amount of labor that has been bestowed upon it by its distinguished editor, Mr. Henry Power. The American editor has made the latest additions, in order fully to cover the time that has elapsed since the last English edition.—*N. Y. Med. Journal*, Jan. 1877.

FOSTER (MICHAEL), M.D., F.R.S.,

Prof. of Physiology in Cambridge Univ., England.

TEXT-BOOK OF PHYSIOLOGY. Latest edition. In one handsome 12mo. vol. of over 800 pages, with 72 illustrations. Cloth, $3 00. (*Just Ready.*)

Dr. Foster has combined in this work the conflicting desiderata in all text-books—comprehensiveness, brevity, and clearness. After a careful perusal of the whole work we can confidently recommend it, both to the student and the practitioner, as being one of the best text-books on physiology extant.—*The London Lancet.*

LEHMANN'S MANUAL OF CHEMICAL PHYSIOLOGY. Translated from the German, with Notes and Additions, by J. CHESTON MORRIS, M.D. With illustrations on wood. In one octavo volume of 336 pages. Cloth, $2 25.

LEHMANN'S PHYSIOLOGICAL CHEMISTRY. Complete in two large octavo volumes of 1200 pages, with 200 illustrations; cloth, $6.

ATTFIELD (*JOHN*), *Ph.D.*,

Professor of Practical Chemistry to the Pharmaceutical Society of Great Britain, &c.

CHEMISTRY, GENERAL, MEDICAL, AND PHARMACEUTICAL;

Including the Chemistry of the U. S. Pharmacopœia. A Manual of the General Principles of the Science, and their Application to Medicine and Pharmacy. Eighth edition, revised by the author. In one handsome royal 12mo. volume of 700 pages, with illustrations. Cloth, $2 50; leather, $3 00. (*Now Ready.*)

We have repeatedly expressed our favorable ion of this work, and on the appearance of a edition of it, little remains for us to say, ex- that we expect this eighth edition to be as ispensable to us as the seventh and previous ions have been. While the general plan and angement have been adhered to, new matter been added covering the observations made e the former edition The present differs from preceding one chiefly in these alterations and bout ten pages of useful tables added in the endix.—*Am. Jour. of Pharmacy*, May, 1879.

standard work like Attfield's Chemistry need be mentioned by its name, without further ments. The present edition contains such al- tions and additions as seemed necessary for demonstration of the latest developments of mical principles, and the latest applications of mistry to pharmacy. The author has bestowed ous labor on the revision, and the extent of information thus introduced may be estimated the fact that the index contains three hun- new references relating to additional mater- —*Druggists' Circular and Chemical Gazette*. y, 1879.

his very popular and meritorious work has reached its eighth edition, which fact speaks he highest terms in commendation of its excel- e. It has now become the principal text-book of chemistry in all the medical colleges in the United States. The present edition contains such alterations and additions as seemed necessary for the demonstration of the latest developments of chemical principles, and the latest applications of chemistry to pharmacy. It is scarcely necessary for us to say that it exhibits chemistry in its present advanced state.—*Cincinnati Medical News*, April, 1879.

The popularity which this work has enjoyed is owing to the original and clear disposition of the facts of the science, the accuracy of the details, and the omission of much which freights many treatises heavily without bringing corresponding instruction to the reader. Dr. Attfield writes for students, and primarily for medical students; he always has an eye to the pharmacopœia and its official preparations; and he is continually putting the matter in the text so that it responds to the questions with which each section is provided. Thus the student learns easily, and can always refresh and test his knowledge.—*Med and Surg. Reporter*, April 19, '79.

We noticed only about two years and a half ago the publication of the preceding edition, and remarked upon the exceptionally valuable character of the work. The work now includes the whole of the chemistry of the pharmacopœia of the United States, Great Britain, and India.—*New Remedies*, May, 1879.

REENE (*WILLIAM H.*), *M.D.*,

Demonstrator of Chemistry in Med. Dept., Univ. of Penna.

A MANUAL OF MEDICAL CHEMISTRY. For the Use of Students.

Based upon Bowman's Medical Chemistry. In one royal 12mo. volume of 312 pages. With illustrations. Cloth, $1 75. (*Now Ready.*)

is well written, and gives the latest views on l chemistry, a subject with which most physi- s are not sufficiently familiar. To those who wish to improve their knowledge in that direc , we can heartily recommend this work as being thy of a careful perusal.—*Phila. Med. and Surg. orter*, April 24, 1880.

The little work before us is one which we think will be studied with pleasure and profit. The descriptions, though brief, are clear, and in most cases sufficient for the purpose This book will, in nearly all cases, meet general approval.—*Am. Journ. of Pharmacy*, April, 1880.

LASSEN (*ALEXANDER*),

Professor in the Royal Polytechnic School, Aix-la-Chapelle.

ELEMENTARY QUANTITATIVE ANALYSIS. Translated with

notes and additions by EDGAR F. SMITH, Ph.D., Assistant Prof. of Chemistry in the Towne Scientific School, Univ. of Penna. In one handsome royal 12mo. volume, of 324 pages, with illustrations; cloth, $2 00. (*Just Ready.*)

is probably the best manual of an elementary are extant, inasmuch as its methods are the best. eaches by examples, commencing with single rminations, followed by separations, and then advancing to the analysis of minerals and such products as are met with in applied chemistry. It is an indispensable book for students in chemistry.—*Boston Journ. of Chemistry*, Oct. 1878.

ALLOWAY (*ROBERT*), *F.C.S.*,

Prof of Applied Chemistry in the Royal College of Science for Ireland, etc.

A MANUAL OF QUALITATIVE ANALYSIS. From the Fifth Lon-

don Edition. In one neat royal 12mo. volume, with illustrations; cloth, $2 75. (*Lately Issued.*)

EMSEN (*IRA*), *M.D., Ph.D.*,

Professor of Chemistry in the Johns Hopkins University, Baltimore.

PRINCIPLES OF THEORETICAL CHEMISTRY, with special reference

to the Constitution of Chemical Compounds. In one handsome royal 12mo. vol. of over 232 pages: cloth, $1 50. (*Just Issued.*)

WMAN'S INTRODUCTION TO PRACTICAL CHEMISTRY, INCLUDING ANALYSIS. Sixth American, from the sixth and revised London edition. With numerous illustrations. In one neat vol., royal 12mo., cloth, $2 25.

WÖHLER AND FITTIG'S OUTLINES OF ORGANIC CHEMISTRY. Translated with additions from the Eighth German Edition. By IRA REMSEN, M.D., Ph.D., Prof. of Chemistry and Physics in Williams College, Mass. In one volume, royal 12mo. of 550 pp., cloth, $3.

FOWNES (GEORGE), Ph.D.

A MANUAL OF ELEMENTARY CHEMISTRY; Theoretical and Practical.

Revised and corrected by HENRY WATTS, B.A., F.R.S., author of "A Dictionary of Chemistry," etc. With a colored plate, and one hundred and seventy-seven illustrations. A new American, from the twelfth and enlarged London edition. Edited by ROBERT BRIDGES, M.D. In one large royal 12mo. volume, of over 1000 pages; cloth, $2 75; leather, $3 25. (*Just Issued.*)

This work, inorganic and organic, is complete in one convenient volume. In its earliest editions it was fully up to the latest advancements and theories of that time. In its present form, it presents, in a remarkably convenient and satisfactory manner, the principles and leading facts of the chemistry of *to-day*. Concerning the manner in which the various subjects are treated, much deserves to be said, and mostly, too, in praise of the book. A review of such a work as *Fownes's Chemistry* within the limits of a book-notice for a medical weekly is simply out of the question.—*Cincinnati Lancet and Clinic*, Dec. 14, 1878.

When we state that, in our opinion, the present edition sustains in every respect the high reputation which its predecessors have acquired and enjoyed, we express therewith our full belief in its intrinsic value as a text-book and work of reference.—*Am. Journ. of Pharm.*, Aug. 1878.

The conscientious care which has been bestowed upon it by the American and English editors renders it still, perhaps, the best book for the student and the practitioner who would keep alive the acquisitions of his student days. It has, indeed, reached a somewhat formidable magnitude with its more than a thousand pages, but with less than this no fair representation of chemistry as it now is can be given. The type is small but very clear, and the sections are very lucidly arranged to facilitate study and reference.—*Med. and Surg. Reporter*, Aug 3, 1878.

The work is too well known to American students to need any extended notice; suffice it to say that the revision by the English editor has been faithfully done, and that Professor Bridges has added some fresh and valuable matter, especially in the inorganic chemistry. The book has always been a favorite in this country, and in its new shape bids fair to retain all its former *prestige*.—*Boston Jour. of Chemistry*, Aug. 1878.

It will be entirely unnecessary for us to make any remarks relating to the general character of Fownes' Manual For over twenty years it has held *the* foremost place as a text-book, and the elaborate and thorough revisions which have been made from time to time leave little chance for any wide-awake rival to step before it.—*Canadian Pharm. Jour.*, Aug. 1878.

As a manual of chemistry it is without a superior in the language.—*Md. Med. Jour.*, Aug. 1878.

BLOXAM (C. L.),

Professor of Chemistry in King's College, London.

CHEMISTRY, INORGANIC AND ORGANIC. From the Second London Edition.

In one very handsome octavo volume, of 700 pages, with about 300 illustrations. Cloth, $4 00; leather, $5 00. (*Lately Issued.*)

We have in this work a complete and most excellent text-book for the use of schools, and can heartily recommend it as such.—*Boston Med. and Surg. Journ.*, May 28, 1874.

The above is the title of a work which we can most conscientiously recommend to students of chemistry. It is as easy as a work on chemistry could be made, at the same time that it presents a full account of that science as it now stands. We have spoken of the work as admirably adapted to the wants of students; it is quite as well suited to the requirements of practitioners who wish to review their chemistry, or have occasion to refresh their memories on any point relating to it. In a word, it is a book to be read by all who wish to know what is the chemistry of the present day.—*American Practitioner*, Nov. 1873.

It would be difficult for a practical chemist and teacher to find any material fault with this most admirable treatise. The author has given us almost a cyclopædia within the limits of a convenient volume, and has done so without penning the *useless* paragraphs too commonly making up a great part of the bulk of many cumbrous works. The progressive scientist is not disappointed when he looks for the record of new and valuable processes and discoveries, while the cautious conservative does not find its pages monopolized by uncertain theories and speculations. A peculiar point of excellence is the crystallized form of expression in which great truths are expressed in very short paragraphs. One is surprised at the brief space allotted to an important topic, and yet, after reading it, he feels that little, if any more should have been said. Altogether, it is seldom you see a text-book so nearly faultless.—*Cincinnati Lancet*, Nov. 1873.

CLOWES (FRANK), D.Sc., London.

Senior Science-Master at the High School, Newcastle-under-Lyme, etc.

AN ELEMENTARY TREATISE ON PRACTICAL CHEMISTRY AND QUALITATIVE INORGANIC ANALYSIS.

Specially adapted for Use in the Laboratories of Schools and Colleges and by Beginners. Second American from the Third and Revised English Edition. In one very handsome royal 12mo. volume of 372 pages, with 47 illustrations. Cloth, $2 50. (*Just Ready.*)

A few notices of the previous edition are appended.

It is short, concise, and eminently practical. We therefore heartily commend it to students, and especially to those who are obliged to dispense with a master. Of course, a teacher is in every way desirable, but a good degree of technical skill and practical knowledge can be attained with no other instructor than the very valuable handbook now under consideration.—*St. Louis Clin. Record*, Oct. 1877.

The work is so written and arranged that it can be comprehended by the student without a teacher, and the descriptions and directions for the various work are so simple, and yet concise, as to be interesting and intelligible. The work is unincumbered with theoretical deductions, dealing wholly with the practical matter, which it is the aim of this comprehensive text-book to impart. The accuracy of the analytical methods are vouched for from the fact that they have all been worked through by the author and the members of his class, from the printed text. We can heartily recommend the work to the student of chemistry as being a reliable and comprehensive one.—*Druggists' Advertiser*, Oct. 15, 1877.

KNAPP'S TECHNOLOGY; or Chemistry Applied to the Arts and to Manufactures. With American additions by Prof. WALTER R. JOHNSON. In two very handsome octavo volumes, with 500 wood engravings, cloth, $6 00.

PARRISH (EDWARD),

Late Professor of Materia Medica in the Philadelphia College of Pharmacy.

A TREATISE ON PHARMACY. Designed as a Text-Book for the Student, and as a Guide for the Physician and Pharmaceutist. With many Formulæ and Prescriptions. Fourth Edition, thoroughly revised, by THOMAS S. WIEGAND. In one handsome octavo volume of 977 pages, with 280 illustrations; cloth, $5 50; leather, $6 50; half Russia, $7. (*Lately Issued.*)

Of Dr. Parrish's great work on pharmacy it only remains to be said that the editor has accomplished his work so well as to maintain, in this fourth edition, the high standard of excellence which it had attained in previous editions, under the editorship of its accomplished author. This has not been accomplished without much labor, and many additions and improvements, involving changes in the arrangement of the several parts of the work, and the addition of much new matter. With the modifications thus effected it constitutes, as now presented, a compendium of the science and art indispensable to the pharmacist, and of the utmost value to every practitioner of medicine desirous of familiarizing himself with the pharmaceutical preparation of the articles which he prescribes for his patients.—*Chicago Med. Journ.*, July, 1874.

The work is eminently practical, and has the rare merit of being readable and interesting, while it preserves a strictly scientific character. The whole work reflects the greatest credit on author, editor and publisher. It will convey some idea of the liberality which has been bestowed upon its production when we mention that there are no less than 280 carefully executed illustrations. In conclusion, we heartily recommend the work, not only to pharmacists, but also to the multitude of medical practitioners who are obliged to compound their own medicines. It will ever hold an honored place on our own book-shelves.—*Dublin Med. Press and Circular*, Aug. 12, 1874.

We expressed our opinion of a former edition in terms of unqualified praise, and we are in no mood to detract from that opinion in reference to the present edition, the preparation of which has fallen into competent hands. It is a book with which no pharmacist can dispense, and from which no physician can fail to derive much information of value to him in practice.—*Pacific Med. and Surg. Journ.*, June, '74.

Perhaps one, if not the most important book upon pharmacy which has appeared in the English language has emanated from the transatlantic press. "Parrish's Pharmacy" is a well-known work on this side of the water, and the fact shows us that a really useful work never becomes merely local in its fame. Thanks to the judicious editing of Mr. Wiegand, the posthumous edition of "Parrish" has been saved to the public with all the mature experience of its author, and perhaps none the worse for a dash of new blood.—*Lond. Pharm. Journal*, Oct. 17, 1874.

GRIFFITH (ROBERT E.), M.D.

A UNIVERSAL FORMULARY, Containing the Methods of Preparing and Administering Officinal and other Medicines. The whole adapted to Physicians and Pharmaceutists. Third edition, thoroughly revised, with numerous additions, by JOHN M. MAISCH, Professor of Materia Medica in the Philadelphia College of Pharmacy. In one large and handsome octavo volume of about 800 pp., cl., $4 50; leather, $5 50. (*Lately Issued.*)

To the druggist a good formulary is simply indispensable, and perhaps no formulary has been more extensively used than the well-known work before us. Many physicians have to officiate, also, as druggists. This is true especially of the country physician, and a work which shall teach him the means by which to administer or combine his remedies in the most efficacious and pleasant manner, will always hold its place upon his shelf. A formulary of this kind is of benefit also to the city physician in largest practice.—*Cincinnati Clinic*, Feb. 21, 1874.

A more complete formulary than it is in its present form the pharmacist or physician could hardly desire. To the first some such work is indispensable, and it is hardly less essential to the practitioner who compounds his own medicines. Much of what is contained in the introduction ought to be committed to memory by every student of medicine. As a help to physicians it will be found invaluable, and doubtless will make its way into libraries not already supplied with a standard work of the kind.—*The American Practitioner*, Louisville, July, '74.

FARQUHARSON (ROBERT), M.D.,

Lecturer on Materia Medica at St. Mary's Hospital, Medical School.

A GUIDE TO THERAPEUTICS AND MATERIA MEDICA. Second American edition, revised by the Author. Enlarged and adapted to the U. S. Pharmacopœia. By FRANK WOODBURY, M.D. In one neat royal 12mo. volume of 498 pages: cloth, $2.25. (*Just Ready.*)

The appearance of a new edition of this convenient and handy book in less than two years may certainly be taken as an indication of its usefulness. Its convenient arrangement, and its terseness, and, at the same time, completeness of the information given, make it a handy book of reference.—*Am. Journ of Pharmacy*, June, 1879.

This work contains in moderate compass such well-digested facts concerning the physiological and therapeutical action of remedies as are reasonably established up to the present time. By a convenient arrangement the corresponding effects of each article in health and disease are presented in parallel columns, not only rendering reference easier, but also impressing the facts more strongly upon the mind of the reader. The book has been adapted to the wants of the American student, and copious notes have been introduced, embodying the latest revision of the Pharmacopœia, together with the antidotes to the more prominent poisons, and such of the newer remedial agents as seemed necessary to the completeness of the work. Tables of weights and measures, and a good alphabetical index end the volume.—*Druggists' Circular and Chemical Gazette*, June, 1879.

It is a pleasure to think that the rapidity with which a second edition is demanded may be taken as an indication that the sense of appreciation of the value of reliable information regarding the use of remedies is not entirely overwhelmed in the cultivation of pathological studies, characteristic of the present day. This work certainly merits the success it has so quickly achieved.—*New Remedies*, July, '79.

CHRISTISON'S DISPENSATORY. With copious additions, and 213 large wood engravings. By R. EGLESFIELD GRIFFITH, M.D. One vol. 8vo., pp. 1000, cloth, $4 00.

CARPENTER'S PRIZE ESSAY ON THE USE OF ALCOHOLIC LIQUORS IN HEALTH AND DISEASE. New edition, with a Preface by D. F. CONDIE, M.D., and explanations of scientific words. In one neat 12mo. volume, pp. 178, cloth, 60 cents.

STILLE (*ALFRED*), *M. D., LL.D., and MAISCH* (*JOHN M.*), *Ph.D.*,
Prof. of Theory and Practice of Medicine and of Clinical Med. in Univ. of Pa.
Prof. of Mat. Med. and Bot. in Phila. Coll. Pharmacy, Secy. to the American Pharmaceutical Association.

THE NATIONAL DISPENSATORY: Containing the Natural History, Chemistry, Pharmacy, Actions and Uses of Medicines, including those recognized in the Pharmacopœias of the United States, Great Britain, and Germany, with numerous references to the French Codex. Second edition, thoroughly revised, with numerous additions. In one very handsome octavo volume of 1692 pages, with 239 illustrations. Extra cloth, $6 75; leather, raised bands, $7 50; half Russia, raised bands and open back, $8 25. (*Now Ready.*)

PREFACE TO THE SECOND EDITION.

The demand which has exhausted in a few months an unusually large edition of the National Dispensatory is doubly gratifying to the authors, as showing that they were correct in thinking that the want of such a work was felt by the medical and pharmaceutical professions, and that their efforts to supply that want have been acceptable. This appreciation of their labors has stimulated them in the revision to render the volume more worthy of the very marked favor with which it has been received. The first edition of a work of such magnitude must necessarily be more or less imperfect; and though but little that is new and important has been brought to light in the short interval since its publication, yet the length of time during which it was passing through the press rendered the earlier portions more in arrears than the later. The opportunity for a revision has enabled the authors to scrutinize the work as a whole, and to introduce alterations and additions wherever there has seemed to be occasion for improvement or greater completeness. The principal changes to be noted are the introduction of several drugs under separate headings, and of a large number of drugs, chemicals, and pharmaceutical preparations classified as allied drugs and preparations under the heading of more important or better known articles: these additions comprise in part nearly the entire German Pharmacopœia and numerous articles from the French Codex. All new investigations which came to the authors' notice up to the time of publication have received due consideration.

The series of illustrations has undergone a corresponding thorough revision. A number have been added, and still more have been substituted for such as were deemed less satisfactory.

The new matter embraced in the text is equal to nearly one hundred pages of the first edition. Considerable as are these changes as a whole, they have been accommodated by an enlargement of the page without increasing unduly the size of the volume.

While numerous additions have been made to the sections which relate to the physiological action of medicines and their use in the treatment of disease, great care has been taken to make them as concise as was possible without rendering them incomplete or obscure. The doses have been expressed in the terms both of troy weight and of the metrical system, for the purpose of making those who employ the Dispensatory familiar with the latter, and paving the way for its introduction into general use.

The Therapeutical Index has been extended by about 2250 new references, making the total number in the present edition about 6000.

The articles there enumerated as remedies for particular diseases are not only those which, in the authors' opinion, are curative, or even beneficial, but those also which have at any time been employed on the ground of popular belief or professional authority. It is often of as much consequence to be acquainted with the worthlessness of certain medicines or with the narrow limits of their power, as to know the well attested virtues of others and the conditions under which they are displayed. An additional value possessed by such an Index is, that it contains the elements of a natural classification of medicines, founded upon an analysis of the results of experience, which is the only safe guide in the treatment of disease.

This evidence of success, seldom paralleled, shows clearly how well the authors have met the existing needs of the pharmaceutical and medical professions. Gratifying as it must be to them, they have embraced the opportunity offered for a thorough revision of the whole work, striving to embrace within it all that might have been omitted in the former edition, and all that has newly appeared of sufficient importance during the time of its collaboration, and the short interval elapsed since the previous publication. After having gone carefully through the volume we must admit that the authors have labored faithfully, and with success, in maintaining the high character of their work as a compendium meeting the requirements of the day, to which one can safely turn in quest of the latest information concerning everything worthy of notice in connection with Pharmacy, Materia Medica, and Therapeutics.—*Am. Jour. of Pharmacy*, Nov. 1879.

It is with great pleasure that we announce to our readers the appearance of a *second* edition of the National Dispensatory. The total exhaustion of the first edition in the short space of six months, is a sufficient testimony to the value placed upon the work by the profession. It appears that the rapid sale of the first edition must have induced both the editors and the publisher to make preparations for a new edition immediately after the first had been issued, for we find a large amount of new matter added and a good deal of the previous text altered and improved, which proves that the authors do not intend to let the grass grow under their feet, but to keep the work up to the time.—*New Remedies*, Nov. 1879.

This is a great work by two of the ablest writers on materia medica in America. The authors have produced a work which, for accuracy and comprehensiveness, is unsurpassed by any work on the subject. There is no book in the English language which contains so much valuable information on the various articles of the materia medica. The work has cost the authors years of laborious study, but they have succeeded in producing a dispensatory which is not only national, but will be a lasting memorial of the learning and ability of the authors who produced it.—*Edinburgh Medical Journal*, Nov. 1879.

It is by far more international or universal than any other book of the kind in our language, and more comprehensive in every sense.—*Pacific Med. and Surg. Journ.*, Oct. 1879.

The National Dispensatory is beyond dispute the very best authority. It is throughout complete in all the necessary details, clear and lucid in its explanations, and replete with references to the most recent writings, where further particulars can be obtained, if desired. Its value is greatly enhanced by the extensive indices—a general index of materia medica, etc., and also an index of therapeutics. It would be a work of supererogation to say more about this well-known work. No practising physician can afford to be without the National Dispensatory.—*Canada Med. and Surg. Journ.*, Feb. 1880.

STILLÉ (ALFRED), M. D.,

Professor of Theory and Practice of Medicine in the University of Penna.

THERAPEUTICS AND MATERIA MEDICA; a Systematic Treatise

on the Action and Uses of Medicinal Agents, including their Description and History. Fourth edition, revised and enlarged. In two large and handsome 8vo. vols. of about 2000 pages. Cloth, $10; leather, $12; half Russia, $13. (*Lately Issued.*)

It is unnecessary to do much more than to announce the appearance of the fourth edition of this well known and excellent work.—*Brit. and For. Med.-Chir. Review*, Oct 1875.

For all who desire a complete work on therapeutics and materia medica for reference, in cases involving medico-legal questions, as well as for information concerning remedial agents, Dr. Stillé's is "*par excellence*" the work. Being out of print, by the exhaustion of former editions, the author has laid the profession under renewed obligations, by the careful revision, important additions, and timely reissuing a work not exactly supplemented by any other in the English language, if in any language. The mechanical execution handsomely sustains the well-known skill and good taste of the publisher.—*St. Louis Med. and Surg. Journal*, Dec. 1874.

From the publication of the first edition "Stillé's Therapeutics" has been one of the classics; its absence from our libraries would create a vacuum which could be filled by no other work in the language, and its presence supplies, in the two volumes of the present edition, a whole cyclopædia of therapeutics.—*Chicago Medical Journal*, Feb. 1875.

The rapid exhaustion of three editions and the universal favor with which the work has been received by the medical profession, are sufficient proof of its excellence as a repertory of practical and useful information for the physician. The edition before us fully sustains this verdict, as the work has been carefully revised and in some portions rewritten, bringing it up to the present time by the admission of chloral and croton-chloral, nitrite of amyl, bichloride of methylene, methylic ether, lithium compounds, gelseminum, and other remedies.—*Am. Journ. of Pharmacy*, Feb. 1875.

We can hardly admit that it has a rival in the multitude of its citations and the fulness of its research into clinical histories, and we must assign it a place in the physician's library; not, indeed, as fully representing the present state of knowledge in pharmacodynamics, but as by far the most complete treatise upon the clinical and practical side of the question.—*Boston Med. and Surg. Journal*, Nov. 5, 1874.

CORNIL (V.), AND RANVIER (L.),

Prof. in the Faculty of Med., Paris. *Prof. in the College of France.*

MANUAL OF PATHOLOGICAL HISTOLOGY. Translated, with

Notes and Additions, by E. O. SHAKESPEARE, M.D., Pathologist and Ophthalmic Surgeon to Philada. Hospital, Lecturer on Refraction and Operative Ophthalmic Surgery in Univ. of Penna., and by HENRY C. SIMES, M D., Demonstrator of Pathological Histology in the Univ. of Pa. In one very handsome octavo volume of over 700 pages, with over 350 illustrations. Cloth, $5 50; leather, $6 50; half Russia, $7. (*Just Ready.*)

The work of Cornil and Ranvier is so well known as a lucid and accurate text-book on its important subject, that no apology is needed in presenting a translation of it to the American profession. It is only necessary to say that the labors of Drs. Shakespeare and Simes have been by no means confined to the task of rendering the work into English. As it appeared in France, in successive portions, between 1868 and 1876, a part of it, at least, was somewhat in arrears of the present state of science, while the diffuseness of other portions rendered condensation desirable. The translators have, therefore, sought to bring the work up to the day, and, at the same time, to reduce it in size, as far as practicable, without impairing its completeness These changes will be found throughout the volume, the most extensive being in the sections devoted to Sarcoma, Carcinoma, Tuberculosis, the Bloodvessels, the Mammæ, and the classification of tumors. Corresponding modifications have been made in the very extensive and beautiful series of illustrations, and every care has been taken in the typographical execution to render it one of the most attractive volumes which have issued from the American press.

We have no hesitation in cordially recommending the English translation of Cornil & Ranvier's "Pathological Histology" as the best work of the kind in any language, and as giving to its readers a trustworthy guide in obtaining a broad and solid basis for the appreciation of the practical bearings of pathological anatomy.—*Am. Journ. of Med. Sciences*, April, 1880.

This important work, in its American dress, is a welcome offering to all students of the subjects which it treats. The great mass of material is arranged naturally and comprehensively. The classification of tumors is clear and full, so far as the subject admits of definition, and this one chapter is worth the price of the book. The illustrations are copious and well chosen. Without the slightest hesitation, the translators deserve honest thanks for placing this indispensable work in the hands of American students.—*Phila. Med. Times*, April 24, 1880

This volume we cordially commend to the profession. It will prove a valuable, almost necessary, addition to the libraries of students who are to be physicians, and to the libraries of students who are physicians.—*American Practitioner*, June, 1880.

Their book is not a collection of the work of others, but has been written in the laboratory beside the microscope. It bears the marks of personal knowledge and investigation upon every page, controlled by and controlling the work of others. . . . In short, its translation has made it the best work in pathology attainable in our language, one that every student certainly ought to have.—*Archives of Medicine*, April, 1880.

This work, in the original, has for years past occupied a prominent place in the library of French pathologists, as we should naturally be led to believe from the reputation of the distinguished authors Now that it has been presented to the English student for the first time, it will be perused with unusual interest. The illustrations are by no means the least valuable part of the work. Indispensable as they are to any work of this nature, in the work before us the artist has succeeded in producing cuts which will prove unusually valuable to the reader. The translation is well done, and gives evidence throughout the volume that it was made by a person thoroughly conversant with the subject.—*N. Y. Med. Gazette*, Feb. 28, 1880.

GLUGE'S ATLAS OF PATHOLOGICAL HISTOLOGY. Translated, with Notes and Additions, by JOSEPH LEIDY, M. D. In one volume, very large imperial quarto, with 320 copper-plate figures, plain and colored, cloth. $4 00.

PAVY'S TREATISE ON THE FUNCTION OF DIGESTION: its Disorders and their Treatment. From the second London edition. In one handsome volume, small octavo, cloth, $2 00.

FENWICK (SAMUEL), M.D.,

Assistant Physician to the London Hospital.

THE STUDENT'S GUIDE TO MEDICAL DIAGNOSIS.

From the Third Revised and Enlarged English Edition. With eighty-four illustrations on wood. In one very handsome volume, royal 12mo., cloth, $2 25. (*Just Issued.*)

GREEN (T. HENRY), M.D.,

Lecturer on Pathology and Morbid Anatomy at Charing-Cross Hospital Medical School, &c.

PATHOLOGY AND MORBID ANATOMY.

Fourth American, from the Fifth Enlarged and Revised English Edition. In one very handsome octavo volume of over 400 pages, with 139 illustrations; cloth, $2 25. (*Just Ready.*)

A few notices of the previous edition are appended.

This is unquestionably one of the best manuals on the subject of pathology and morbid anatomy that can be placed in the student's hands, and we are glad to see it kept up to the times by new editions. Each edition is carefully revised by the author, with the view of making it include the most recent advances in pathology, and of omitting whatever may have become obsolete.—*N. Y. Med. Jour.*, Feb. 1879.

The treatise of Dr. Green is compact, clearly expressed, up to the times, and popular as a text-book, both in England and America. The cuts are sufficiently numerous, and usually well made. In the present edition, such new matter has been added as was necessary to embrace the later results in pathological research. No doubt it will continue to enjoy the favor it has received at the hands of the profession.—*Med. and Surg. Reporter*, Feb. 1, 1879.

For practical, ordinary daily use, this is undoubtedly the best treatise that is offered to students of pathology and morbid anatomy.—*Cincinnati Lancet and Clinic*, Feb. 8, 1879.

BRISTOWE (JOHN SYER), M.D., F.R.C.P.,

Physician and Joint Lecturer on Medicine, St. Thomas's Hospital.

A TREATISE ON THE PRACTICE OF MEDICINE.

Second American edition, revised by the Author. Edited, with Additions, by JAMES H. HUTCHINSON, M.D., Physician to the Penna. Hospital. In one handsome octavo volume of nearly 1200 pages. With illustrations. Cloth, $5 00; leather, $6 00; half Russia, $6 50. (*Now Ready.*)

The second edition of this excellent work, like the first, has received the benefit of Dr. Hutchinson's annotations, by which the phases of disease which are peculiar to this country are indicated, and thus a treatise which was intended for British practitioners and students is made more practically useful on this side of the water. We see no reason to modify the high opinion previously expressed with regard to Dr. Bristowe's work, except by adding our appreciation of the careful labors of the author in following the lateral growth of medical science. The chapter on diseases of the skin and of the nervous system, with a new one on insanity compiled from the best sources outside of the author's own long experience, and the valuable portion relating to general pathology, aid greatly in completing an exceptionally good book for purposes of reference and instruction.—*Boston Medical and Surgical Journal*, February, 1880.

What we said of the first edition, we can, with increased emphasis, repeat concerning this: "Every page is characterised by the utterances of a thoughtful man. What has been said, has been well said, and the book is a fair reflex of all that is *certainly known* on the subjects considered."—*Ohio Med. Recorder*, Jan. 7, 1880.

The views of the author are expressed with precision and sufficient promptness to impress the student with the weight of his authority; and should the medical professor differ on any subject from his doctrine, he will need to find strong arguments to carry his class to the opposite conclusion.—*N. O. Med. and Surg. Journ.*, Feb. 1880.

The reader will find every conceivable subject connected with the practice of medicine ably presented, in a style at once clear, interesting, and concise. The additions made by Dr. Hutchinson are appropriate and practical, and greatly add to its usefulness to American readers.—*Buffalo Med. and Surg. Journ.*, March, 1880.

We regard it as an excellent work for students and for practitioners. It is clearly written, the author's style is attractive, and it is especially to be commended for its excellent exposition of the pathology and clinical phenomena of disease.—*St. Louis Cin. Record*, Feb. 1880.

HABERSHON (S. O.) M.D.

Senior Physician to and late Lecturer on the Principles and Practice of Medicine at Guy's Hospital, etc.

ON THE DISEASES OF THE ABDOMEN, COMPRISING THOSE

of the Stomach, and other parts of the Alimentary Canal, Œsophagus, Cæcum, Intestines, and Peritoneum. Second American, from the third enlarged and revised English edition. With illustrations. In one handsome octavo volume of over 500 pages. Cloth, $3 50. (*Now Ready.*)

This valuable treatise on diseases of the stomach and abdomen has been out of print for several years, and is therefore not so well known to the profession as it deserves to be. It will be found a cyclopædia of information, systematically arranged, on all diseases of the alimentary tract, from the mouth to the rectum. A fair proportion of each chapter is devoted to symptoms, pathology, and therapeutics. The present edition is fuller than former ones in many particulars, and has been thoroughly revised and amended by the author. Several new chapters have been added, bringing the work fully up to the times, and making it a volume of interest to the practitioner in every field of medicine and surgery. Perverted nutrition is in some form associated with all diseases we have to combat, and we need all the light that can be obtained on a subject so broad and general. Dr. Habershon's work is one that every practitioner should read and study for himself.—*N. Y. Med. Journ*, April, 1879.

LA ROCHE ON YELLOW FEVER, considered in its Historical, Pathological, Etiological, and Therapeutical Relations. In two large and handsome octavo volumes of nearly 1500 pp., cloth. $7 00.

STOKES' LECTURES ON FEVER. Edited by JOHN WILLIAM MOORE, M.D., Assistant Physician to the Cork Street Fever Hospital. In one neat 8vo volume, cloth, $2 00.

HOLLAND'S MEDICAL NOTES AND REFLECTIONS. 1 vol 8vo., pp. 500, cloth. $3 50.

BARLOW'S MANUAL OF THE PRACTICE OF MEDICINE. With Additions by D. F. CONDIE, M D. 1 vol. 8vo., pp. 600, cloth. $2 50.

TODD'S CLINICAL LECTURES ON CERTAIN ACUTE DISEASES. In one neat octavo volume, of 320 pp. cloth. $2 50.

FLINT (AUSTIN), M.D.,

Professor of the Principles and Practice of Medicine in Bellevue Med. College, N. Y.

A TREATISE ON THE PRINCIPLES AND PRACTICE OF MEDICINE; designed for the use of Students and Practitioners of Medicine. Fifth edition, entirely rewritten and much improved. In one large and closely printed octavo volume of 1153 pp. Cloth, $5 50; leather, $6 50; very handsome half Russia, raised bands, $7. (*Just Ready.*)

EXTRACT FROM THE AUTHOR'S PREFACE.

In preparing the fifth edition of this treatise, the author has been thoroughly mindful of the progress of medicine since the publication of the fourth edition in 1873. Time and labor have not been spared in the endeavor to bring the work in all respects up to the present state of medical knowledge.

Dr. William H. Welch, Lecturer on Pathological Histology in the Bellevue Hospital Medical College, has contributed in Part I. the first seven chapters, embracing the general pathology of the solid tissues and of the blood. He has also revised, and in great part rewritten, the descriptions of the anatomical characters of the diseases considered in the rest of the volume. It is believed that these portions of the work will serve as a digest of the essential facts pertaining to general and special pathological anatomy, as far as this important branch of study bears upon practical medicine.

In the other portions of the treatise many changes will be found, which have somewhat enlarged the size of the volume, in spite of the omission of a considerable amount of matter, and the rewriting of many portions with a special view to condensation. Among these changes may be mentioned numerous improvements in the arrangement, including the classification of the diseases of the nervous system on an anatomical in place of a symptomatic basis, and the consideration of various diseases not embraced in previous editions. In short, the eliminations, substitutions, and additions render the present edition virtually a new work.

In making changes, the author has not been influenced by any sense of obligation to maintain consistency of views with the previous editions of this treatise, or with other works which he has written. If statements be found to vary from those made at a prior date, the simple explanation is that the latter, in the light of more recent reflection and enlarged knowledge, seem to him no longer tenable. He has endeavored to regard his own past writings, in this point of view, divested of the partiality of authorship, and to subject them to as critical an examination as if they were the writings of another.

BY THE SAME AUTHOR.

CLINICAL MEDICINE; a Systematic Treatise on the Diagnosis and Treatment of Diseases. Designed for Students and Practitioners of Medicine. In one large and handsome octavo volume of 795 pages; cloth, $4 50; leather, $5 50; half Russia, $6. (*Now Ready.*)

The eminent teacher who has written the volume under consideration has recognized the needs of the American profession, and the result is all that we could wish. The style in which it is written is peculiarly the author's; it is clear and forcible, and marked by those characteristics which have rendered him one of the best writers and teachers this country has ever produced. We have not space for so full a consideration of this remarkable work as we would desire.—*St. Louis Clin. Record*, Oct. 1879.

It is here that the skill and learning of the great clinician are displayed. He has given us a storehouse of medical knowledge, excellent for the student, convenient for the practitioner, the result of a long life of the most faithful clinical work, collected by an energy as vigilant and systematic as untiring, and weighed by a judgment no less clear than his observation is close.—*Archives of Medicine*, Dec. 1879.

To give an adequate and useful conspectus of the extensive field of modern clinical medicine is a task of no ordinary difficulty; but to accomplish this consistently, with brevity and clearness, the different subjects and their several parts receiving the attention which, relatively to their importance, medical opinion claims for them, is still more difficult. This task we feel bound to say has been executed with more than partial success by Dr Flint, whose name is already familiar to students of advanced medicine in this country as that of the author of two works of great merit on special subjects, and of numerous papers, exhibiting much originality and extensive research.—*The Dublin Journal*, Dec. 1879.

There is every reason to believe that this book will be well received. The active practitioner is frequently in need of some work that will enable him to obtain information in the diagnosis and treatment of cases with comparatively little labor. Dr. Flint has the faculty of expressing himself clearly, and at the same time so concisely as to enable the searcher to traverse the entire ground of his search, and at the same time obtain all that is essential, without plodding through an interminable space.—*N. Y. Med. Jour.*, Nov. 1879.

The great object is to place before the reader the latest observations and experience in diagnosis and treatment. Such a work is especially valuable to students. It is complete in its special design, and yet so condensed, that he can by its aid, keep up with the lectures on practice without neglecting other branches. It will not escape the notice of the practitioner that such a work is most valuable in culling points in diagnosis and treatment in the intervals between the daily rounds of visits, since he can in a few minutes refresh his memory, or learn the latest advance in the treatment of diseases which demand his instant attention.—*Cincinnati Lancet and Clinic*, Oct. 25, 1879.

BY THE SAME AUTHOR.

ESSAYS ON CONSERVATIVE MEDICINE AND KINDRED TOPICS. In one very handsome royal 12mo. volume. Cloth, $1 38. (*Just Issued.*)

DAVIS'S CLINICAL LECTURES ON VARIOUS IMPORTANT DISEASES; being a collection of the Clinical Lectures delivered in the Medical Wards of Mercy Hospital, Chicago. Edited by FRANK H DAVIS, M.D. Second edition, enlarged. In one handsome royal 12mo. volume. Cloth, $1 75.

THE CYCLOPÆDIA OF PRACTICAL MEDICINE: comprising Treatises on the Nature and Treatment of Diseases, Materia Medica and Therapeutics, Diseases of Women and Children, Medical Jurisprudence, etc. etc. By DUNGLISON, FORBES, TWEEDIE, and CONOLLY. In four large super-royal octavo volumes, of 3254 double-columned pages, strongly and handsomely bound in leather, $15; cloth, $11

STURGES'S INTRODUCTION TO THE STUDY OF CLINICAL MEDICINE. Being a Guide to the Investigation of Disease. In one handsome 12mo volume, cloth, $1 25. (*Lately Issued.*)

RICHARDSON (*BENJ. W.*), *M.D., F.R.S., M.A., LL.D., F.S.A.*,
Fellow of the Royal College of Physicians, London.

PREVENTIVE MEDICINE. In one octavo volume of about 500 pages. (*In Press.*)

The immense strides taken by medical science during the last quarter of a century have had no more conspicuous field of progress than the causation of disease. Not only has this led to marked advance in therapeutics, but it has given rise to a virtually new department of medicine—the prevention of disease—more important, perhaps, in its ultimate results than even the investigation of curative processes. Yet thus far there has been no attempt to gather into a systematic and intelligible shape the accumulation of knowledge thus far acquired on this most interesting subject. Fortunately, the task has been at last undertaken by a writer who of all others is, perhaps, best qualified for its performance, and the result of his labors can hardly fail to mark an epoch in the history of medical science. The plan adopted for the execution of this novel design can best be explained in his own words:—

"With the object here expressed I write this volume. I have nothing to say in it that has any relation to the cure of disease, but I base it nevertheless on the curative side of medical learning. In other words, I trace the diseases from their actual representation as they exist before us, in their natural progress after their birth, as far as I am able, back to their origins, and try to seek the conditions out of which they spring. Thereupon I endeavor further to analyze those conditions, to see how far they are removable and how far they are avoidable."

WOODBURY (*FRANK*). *M.D.*,
Physician to the German Hospital, Philadelphia, late Chief Assist. to Med. Clinic, Jeff. College Hospital, etc.

A HANDBOOK OF THE PRINCIPLES AND PRACTICE OF Medicine; for the use of Students and Practitioners. Based upon Husband's Handbook of Practice. In one neat volume, royal 12mo. (*Preparing.*)

FOTHERGILL (*J. MILNER*), *M.D. Edin., M.R.C.P. Lond.*,
Asst. Phys. to the West Lond. Hosp.; Asst. Phys. to the City of Lond. Hosp., etc.

THE PRACTITIONER'S HANDBOOK OF TREATMENT; Or, the Principles of Therapeutics. Second edition, revised and enlarged. In one very neat octavo volume of about 650 pages. Cloth, $4 00; very handsome half Russia, $5 50. (*Just Ready.*)

The junior members of the profession will find in it a work that should not only be read, but carefully studied. It will assist them in the proper selection and combination of therapeutical agents best adapted to each case and condition, and enable them to prescribe intelligently and successfully. To do full justice to a work of this scope and character will be impossible in a review of this kind. The book itself must be read to be fully appreciated —*St. Louis Courier of Medicine*, Nov. 1880.

The author merits the thanks of every well-educated physician for his efforts toward rationalizing the treatment of diseases upon the scientific basis of physiology. Every chapter, every line, has the impress of a master hand, and while the work is thoroughly scientific in every particular, it presents to the thoughtful reader all the charms and beauties of a well-written novel. No physician can well afford to be without this valuable work, for its originality makes it fill a niche in medical literature hitherto vacant.—*Nashville Journ. of Med. and Surg.*, Oct. 1880.

Throughout the work, while room is left for difference of opinion in matters of detail, the main courses of treatment are so carefully founded on well-established principles, that no essential difference is felt to be possible. The closing chapter contains much concentrated worldly wisdom; and, if carefully read, digested, and assimilated, will in many an emergency, stand the young medical man in good stead.—*Lond. Med. Record*, Oct. 12, 1880.

FINLAYSON (*JAMES*), *M.D.*,
Physician and Lecturer on Clinical Medicine in the Glasgow Western Infirmary, etc.

CLINICAL DIAGNOSIS; A Handbook for Students and Practitioners of Medicine. In one handsome 12mo. volume, of 546 pages, with 85 illustrations. Cloth, $2 63. (*Just Issued.*)

The book is an excellent one, clear, concise, convenient, practical. It is replete with the very knowledge the student needs when he quits the lecture-room and the laboratory for the ward and sick-room, and does not lack in information that will meet the wants of experienced and older men.—*Phila. Med. Times*, Jan. 4, 1879.

This is one of the really useful books. It is attractive from preface to the final page, and ought to be given a place on every office table, because it contains in a condensed form all that is valuable in semeiology and diagnostics to be found in bulkier volumes, and because in its arrangement and complete index, it is unusually convenient for quick reference in any emergency that may come upon the busy practitioner. —*N. O. Med. Journ.*, Jan. 1879.

WATSON (*THOMAS*), *M.D., &c.*

LECTURES ON THE PRINCIPLES AND PRACTICE OF PHYSIC. Delivered at King's College, London. A new American, from the Fifth revised and enlarged English edition. Edited, with additions, and several hundred illustrations, by HENRY HARTSHORNE, M.D., Professor of Hygiene in the University of Pennsylvania. In two large and handsome 8vo. vols. Cloth, $9 00; leather, $11 00. (*Lately Published.*)

HARTSHORNE (*HENRY*), *M.D.*,
Professor of Hygiene in the University of Pennsylvania

ESSENTIALS OF THE PRINCIPLES AND PRACTICE OF MEDICINE. A handy-book for Students and Practitioners. Fourth edition, revised and improved. With about one hundred illustrations. In one handsome royal 12mo volume, of about 550 pages, cloth, $2 63; half bound, $2 88. (*Lately Issued.*)

REYNOLDS (J. RUSSELL). M.D.,

Prof. of the Principles and Practice of Medicine in Univ. College, London.

A SYSTEM OF MEDICINE WITH NOTES AND ADDITIONS BY HENRY HARTSHORNE, M.D., late Professor of Hygiene in the University of Penna. In three large and handsome octavo volumes, containing 3052 closely printed double-columned pages, with numerous illustrations. *Sold only by subscription.* Price per vol., in cloth, $5.00; in sheep, $6.00: half Russia, raised bands, $6.50. Per set in cloth, $15; sheep, $18; half Russia, $19.50

VOLUME I. (*just ready*) contains GENERAL DISEASES and DISEASES OF THE NERVOUS SYSTEM.
VOLUME II. (*just ready*) contains DISEASES OF RESPIRATORY and CIRCULATORY SYSTEMS.
VOLUME III. (*just ready*) contains DISEASES OF THE DIGESTIVE and BLOOD GLANDULAR SYSTEMS, OF THE URINARY ORGANS, OF THE FEMALE REPRODUCTIVE SYSTEM, and OF THE CUTANEOUS SYSTEM.

Reynolds's SYSTEM OF MEDICINE, recently completed, has acquired, since the first appearance of the first volume, the well-deserved reputation of being the work in which modern British medicine is presented in its fullest and most practical form. This could scarce be otherwise in view of the fact that it is the result of the collaboration of the leading minds of the profession, each subject being treated by some gentleman who is regarded as its highest authority—as for instance, Diseases of the Bladder by Sir HENRY THOMPSON, Malpositions of the Uterus by GRAILY HEWITT, Insanity by HENRY MAUDSLEY, Consumption by J. HUGHES BENNET, Diseases of the Spine by CHARLES BLAND RADCLIFFE, Pericarditis by FRANCIS SIBSON, Alcoholism by FRANCIS E. ANSTIE, Renal Affections by WILLIAM ROBERTS, Asthma by HYDE SALTER, Cerebral Affections by H. CHARLTON BASTIAN, Gout and Rheumatism by ALFRED BARING GARROD, Constitutional Syphilis by JONATHAN HUTCHINSON, Diseases of the Stomach by WILSON FOX, Diseases of the Skin by BALMANNO SQUIRE, Affections of the Larynx by MORELL MACKENZIE, Diseases of the Rectum by BLIZARD CURLING, Diabetes by LAUDER BRUNTON, Intestinal Diseases by JOHN SYER BRISTOWE, Catalepsy and Somnambulism by THOMAS KING CHAMBERS, Apoplexy by J. HUGHLINGS JACKSON, Angina Pectoris by Professor GAIRDNER, Emphysema of the Lungs by Sir WILLIAM JENNER, etc etc. All the leading schools in Great Britain have contributed their best men in generous rivalry, to build up this monument of medical science. St. Bartholomew's, Guy's, St Thomas's, University College, St Mary's in London, while the Edinburgh, Glasgow, and Manchester schools are equally well represented, the Army Medical School at Netley, the military and naval services, and the public health boards. That a work conceived in such a spirit, and carried out under such auspices should prove an indispensable treasury of facts and experience, suited to the daily wants of the practitioner, was inevitable, and the success which it has enjoyed in England, and the reputation which it has acquired on this side of the Atlantic, have sealed it with the approbation of the two pre-eminently practical nations.

Its large size and high price having kept it beyond the reach of many practitioners in this country who desire to possess it, a demand has arisen for an edition at a price which shall render it accessible to all. To meet this demand the present edition has been undertaken. The five volumes and five thousand pages of the original have, by the use of a smaller type and double columns, been compressed into three volumes of over three thousand pages, clearly and handsomely printed, and offered at a price which renders it one of the cheapest works ever presented to the American profession.

But not only is the American edition more convenient and lower priced than the English; it is also better and more complete. Some years having elapsed since the appearance of a portion of the work, additions are required to bring up the subjects to the existing condition of science. Some diseases, also, which are comparatively unimportant in England, require more elaborate treatment to adapt the articles devoted to them to the wants of the American physician; and there are points on which the received practice in this country differs from that adopted abroad. The supplying of these deficiencies has been undertaken by HENRY HARTSHORNE, M.D., late Professor of Hygiene in the University of Pennsylvania, who has endeavored to render the work fully up to the day, and as useful to the American physician as it has proved to be to his English brethren. The number of illustrations has also been largely increased, and no effort spared to render the typographical execution unexceptionable in every respect.

Really too much praise can scarcely be given to this noble book. It is a cyclopædia of medicine written by some of the best men of Europe. It is full of useful information such as one finds frequent need of in one's daily work. As a book of reference it is invaluable. It is up with the times. It is clear and concentrated in style, and its form is worthy of its famous publisher.—*Louisville Med. News*, Jan. 31, 1880.

"Reynolds' System of Medicine" is justly considered the most popular work on the principles and practice of medicine in the English language. The contributors to this work are gentlemen of well-known reputation on both sides of the Atlantic. Each gentleman has striven to make his part of the work as practical as possible, and the information contained is such as is needed by the busy practitioner.—*St. Louis Med. and Surg. Journ.*, Jan. '80.

Dr. Hartshorne has made ample additions and revisions, all of which give increased value to the volume, and render it more useful to the American practitioner. There is no volume in English medical literature more valuable, and every purchaser will, on becoming familiar with it, congratulate himself on the possession of this vast storehouse of information, in regard to so many of the subjects with which he should be familiar.—*Gaillard's Med. Journ.*, Feb. 1880.

There is no medical work which we have in times past more frequently and fully consulted when perplexed by doubts as to treatment, or by having unusual or apparently inexplicable symptoms presented to us than "Reynolds' System of Medicine." Among its contributors are gentlemen who are as well known by reputation upon this side of the Atlantic as in Great Britain, and whose right to speak with authority upon the subjects about which they have written, is recognized the world over. They have evidently striven to make their essays as practical as possible, and while these are sufficiently full to entitle them to the name of monographs, they are not loaded down with such an amount of detail as to render them wearisome to the general reader. In a word, they contain just that kind of information which the busy practitioner frequently finds himself in need of. In order that any deficiencies may be supplied, the publishers have committed the preparation of the book for the press to Dr. Henry Hartshorne, whose judicious notes distributed throughout the volume afford abundant evidence of the thoroughness of the revision to which he has subjected it.—*Am. Jour. Med. Sciences*, Jan. 1880.

BARTHOLOW (ROBERTS), A.M., M.D., LL.D.

Prof. of Materia Medica and General Therapeutics in the Jeff. Med. Coll. of Phila., &c.

A PRACTICAL TREATISE ON ELECTRICITY IN ITS APPLICATION TO MEDICINE.

In one very handsome 8vo. volume of about 300 pages, with numerous illustrations. (*Very shortly.*)

The constantly increasing therapeutic use of electricity, and the absence of a concise guide suited to the wants of the general practitioner, have induced the author to prepare the present volume. His object has been to present the most advanced state of existing knowledge in a form divested of unnecessary technicalities, keeping constantly in view the practical needs of the student and physician.

As the volume is founded upon a course of lectures delivered in the Jefferson Medical College during 1880, its adaptation to its purpose is insured. Dr. Bartholow's power of lucid exposition is well known, and is particularly desirable in a subject such as this, treated from the standpoint of the general practitioner and not of the specialist.

MITCHELL (S. WEIR), M.D.,

Phys. to Orthopædic Hospital and the Infirmary for Dis. of the Nervous System, Philn., &c. &c.

LECTURES ON DISEASES OF THE NERVOUS SYSTEM, ESPECIALLY IN WOMEN.

In one very handsome 12mo. volume of about 250 pages, with five lithographic plates. Cloth, $1 75 (*Just Ready*)

The life-long devotion of the author to the subjects discussed in this volume has rendered it eminently desirable that the results of his labors should be embodied for the benefit of those who may experience the difficulties connected with the treatment of this class of disease. Many of these lectures are fresh studies of hysterical affections; others treat of the modifications his views have undergone in regard to certain forms of treatment, while, throughout the whole work he has been careful to keep in view the practical lessons of his cases. The scope of the volume may be gathered from the following

CONDENSED SUMMARY OF CONTENTS.

LECTURE I.—The Paralyses of Hysteria. II. Hysterical Motor Ataxia.—Hysterical Paresis. III. Mimicry of Disease. IV. Mimicry of Disease. V. Unusual Forms of Spasmodic Affections in Women. VI. Tremor—Chronic Spasms. VII. Chorea of Childhood. VIII. Habit Chorea. IX. Disorders of Sleep in Nervous or Hysterical Persons. X. Vaso Motor and Respiratory Disorders in the Nervous or Hysterical. XI. Hysterical Aphonia. XII. Gastro Intestinal Disorders of Hysteria XIII. The Treatment of Nervous Exhaustion and Hysteria by Seclusion, Rest, Massage, Electricity, and Full Feeding.

HAMILTON (ALLAN McLANE), M.D.,

Attending Physician at the Hospital for Epileptics and Paralytics, Blackwell's Island, N.Y., and at the Out-Patients' Department of the New York Hospital.

NERVOUS DISEASES; THEIR DESCRIPTION AND TREATMENT.

In one handsome octavo volume of 512 pages, with 53 illus.; cloth, $3 50. (*Lately Issued.*)

CLINICAL OBSERVATIONS ON FUNCTIONAL NERVOUS DISORDERS. By C. HANDFIELD JONES, M.D., Physician to St. Mary's Hospital, &c. Second and American Edition. In one handsome octavo volume of 348 pages, cloth, $3 25.

MORRIS (MALCOLM), M.D.,

Joint Lecturer on Dermatology, St. Mary's Hospital Med. School.

SKIN DISEASES, Including their Definitions, Symptoms, Diagnosis, Prognosis, Morbid Anatomy, and Treatment. A Manual for Students and Practitioners.

In one 12mo. volume of over 300 pages. With illustrations. Cloth, $1 75. (*Now Ready.*)

To physicians who would like to know something about skin diseases, so that when a patient presents himself for relief they can make a correct diagnosis and prescribe a rational treatment, we unhesitatingly recommend this little book of Dr. Morris. The affections of the skin are described in a terse, lucid manner, and their several characteristics so plainly set forth that diagnosis will be easy. The treatment in each case is such as the experience of the most eminent dermatologists advise.—*Cincinnati Medical News*, April, 1880.

This is emphatically a learner's book; for we can safely say, so far as our judgment goes, that in the whole range of medical literature of a like scope, there is no book which for clearness of expression and methodical arrangement is better adapted to promote a rational conception of dermatology, a branch confessedly difficult and perplexing to the beginner.—*St. Louis Courier of Medicine*, April, 1880.

The author of this manual has evidently a full and intimate acquaintance with the literature of dermatology, and with the most recent developments and appliances of cutaneous medicine. He has produced a plain, practical book, by aid of which, who so chooses may train his eye to the recognition of light but significant differences. The descriptions are neither too vague nor over-refined; the directions for treatment are clear and succinct.—*London Brain*, April, 1880

The author's task has been well done and has produced one of the best recent works upon the difficult subject of which it treats; there is no work published which gives a better view of the elementary facts and principles of dermatology.—*New Orleans Medical and Surgical Journal*, April, 1880.

FOX (TILBURY), M.D., F.R.C.P., and T. C. FOX, B.A., M.R.C.S.,

Physician to the Department for Skin Diseases, University College Hospital.

EPITOME OF SKIN DISEASES. WITH FORMULÆ.

FOR STUDENTS AND PRACTITIONERS. Second edition, thoroughly revised and greatly enlarged. In one very handsome 12mo. volume of 210 pages. Cloth, $1 38. (*Just Issued.*)

FLINT (AUSTIN), M.D.,

Professor of the Principles and Practice of Medicine in Bellevue Hospital Med. College, N. Y.

A MANUAL OF PERCUSSION AND AUSCULTATION; of the Physical Diagnosis of Diseases of the Lungs and Heart, and of Thoracic Aneurism. Second edition. In one handsome royal 12mo. volume: cloth, $1 63. (*Just Ready.*)

Prof. Flint is so well known as a medical teacher and writer that it seems superfluous to state that the subject has been treated in a thorough and systematic manner. In revising it for a second edition the author has confined himself to such additions as seem likely to render it more useful, not only to students engaged in the practical study of the subject, but also to practitioners as a handbook for ready reference, and we do not hesitate in saying that it would prove a valuable addition to every physician's library.—*Med. and Surg. Reporter*, March 13 1880.

The little work before us has already become a standard one, and has become extensively adopted as a text-book. There is certainly none better. It contains the substance of the lessons which the author has for many years given, in connection with practical instruction in auscultation and percussion, to private classes, composed of medical students and practitioners.—*Cincinnati Med. News*, Feb. 1880.

BY THE SAME AUTHOR.

PHTHISIS: ITS MORBID ANATOMY, ETIOLOGY, SYMPTOMATIC EVENTS AND COMPLICATIONS, FATALITY AND PROGNOSIS, TREATMENT AND PHYSICAL DIAGNOSIS; in a series of Clinical Studies. By AUSTIN FLINT, M D., Prof. of the Principles and Practice of Medicine in Bellevue Hospital Med. College, New York. In one handsome octavo volume: $3 50. (*Lately Issued.*)

BY THE SAME AUTHOR.

A PRACTICAL TREATISE ON THE DIAGNOSIS, PATHOLOGY, AND TREATMENT OF DISEASES OF THE HEART. Second revised and enlarged edition. In one octavo volume of 550 pages, with a plate, cloth, $4.

Dr. Flint chose a difficul subject for his researches, and has shown remarkable powers of observation and reflection, as well as great industry, in his treatment of it. His book must be considered the fullest and clearest practical treatise on those subjects and should be in the hands of all practitioners and students. It is a credit to American medical literature. —*Amer. Journ. of the Med. Sciences*, July, 1860.

BY THE SAME AUTHOR.

A PRACTICAL TREATISE ON THE PHYSICAL EXPLORATION OF THE CHEST AND THE DIAGNOSIS OF DISEASES AFFECTING THE RESPIRATORY ORGANS. Second and revised edition. In one handsome octavo volume of 595 pages, cloth, $4 50.

BROWN (LENNOX), F.R.C.S. Ed.,

Senior Surgeon to the Central London Throat and Ear Hospital, etc.

THE THROAT AND ITS DISEASES. With one hundred Typical Illustrations in colors and fifty wood engravings, designed and executed by the author. In one very handsome imperial octavo volume of 351 pages; cloth, $5 00. (*Just Ready.*)

SEILER (CARL), M.D.,

Lecturer on Laryngoscopy at the Univ of Penna., Chief of the Throat Dispensary at the Univ. Hospital, Phila., etc.

HANDBOOK OF DIAGNOSIS AND TREATMENT OF DISEASES OF THE THROAT AND NASAL CAVITIES. In one handsome royal 12mo. volume, of 156 pages, with 35 illustrations; cloth, $1. (*Just Ready.*)

We most heartily commend this book as showing sound judgment in practice, and perfect familiarity with the literature of the specialty it so ably epitomizes.— *Philada. Med. Times*, July 5, 1879.

A convenient little handbook, clear, concise, and accurate in its method, and admirably fulfilling its purpose of bringing the subject of which it treats within the comprehension of the general practitioner.—*N. C. Med. Jour.*, June, 1879.

WILLIAMS'S PULMONARY CONSUMPTION; its Nature, Varieties, and Treatment. With an Analysis of One Thousand Cases to exemplify its duration. In one neat octavo volume of about 350 pages; cloth, $2 50.

BLADE ON DIPHTHERIA; its Nature and Treatment, with an account of the History of its Prevalence in various Countries. Second and revised edition. In one neat royal 12mo. volume, cloth, $1 25.

WALSHE ON THE DISEASES OF THE HEART AND GREAT VESSELS. Third American Edition. In 1 vol. 8vo., 420 pp., cloth, $3 00.

CHAMBERS'S MANUAL OF DIET AND REGIMEN IN HEALTH AND SICKNESS. In one handsome octavo volume. Cloth, $2 75.

LA ROCHE ON PNEUMONIA. 1 vol. 8vo., cloth, of 500 pages. Price, $3 00.

WILSON'S STUDENT'S BOOK OF CUTANEOUS MEDICINE and DISEASES OF THE SKIN. In one very handsome royal 12mo. volume. $3 50.

FULLER ON DISEASES OF THE LUNGS AND AIR-PASSAGES. Their Pathology, Physical Diagnosis, Symptoms, and Treatment. From the second and revised English edition. In one handsome octavo volume of about 500 pages: cloth, $3 50.

SMITH ON CONSUMPTION; ITS EARLY AND REMEDIABLE STAGES. 1 vol. 8vo., pp. 264 $2 25.

BASHAM ON RENAL DISEASES: a Clinical Guide to their Diagnosis and Treatment. With illustrations In one 12mo. vol. of 304 pages, cloth, $2 00.

LECTURES ON THE STUDY OF FEVER. By A. HUDSON, M.D., M.R.I.A., Physician to the Meath Hospital. In one vol. 8vo., cloth, $2 50.

A TREATISE ON FEVER. By ROBERT D. LYONS, K.C.C. In one octavo volume of 362 pages, cloth $2 25.

HILLIER'S HANDBOOK OF SKIN DISEASES, for Students and Practitioners. Second Am Ed. In one royal 12mo. vol. of 338 pp. With illustrations. Cloth, $2 25.

BUMSTEAD (FREEMAN J.), M.D., LL.D.,

Professor of Venereal Diseases at the Col. of Phys. and Surg., New York, &c.

THE PATHOLOGY AND TREATMENT OF VENEREAL DISEASES.

Including the results of recent investigations upon the subject. Fourth edition, revised and largely rewritten with the co-operation of R. W. Taylor, M.D., of New York, Prof. of Dermatology in the Univ. of Vt. In one large and handsome octave volume of 835 pages, with 138 illustrations. Cloth, $4 75; leather, $5 75; half Russia, $6 25. (*Now Ready.*)

This work, on its first appearance, immediately took the position of a standard authority on its subject wherever the language is spoken, and the success of an Italian translation shows that it is regarded with equal favor on the Continent of Europe. In repeated editions the author labored sedulously to render it more worthy of its reputation, and in the present revision no pains have been spared to perfect it as far as possible. Several years having elapsed since the publication of the third edition, much material has been accumulated during the interval by the industry of syphilologists, and new views have been enunciated. All this so far as confirmed by observation and experience, has been incorporated; many portions of the volume been rewritten, the series of illustrations has been enlarged and improved, and the whole may be regarded rather as a new work than as a new edition. It is confidently presented as fully on a level with the most advanced condition of syphilology, and as a work to which the practitioner may refer with the certainty of finding clearly and succinctly set forth whatever falls within the scope of such a treatise.

We have to congratulate our countrymen upon the truly valuable addition which they have made to American literature. The careful estimate of the value of the volume, which we have made, justifies us in declaring that this is the best treatise on venereal diseases in the English language, and, we might add, if there is a better in any other tongue we cannot name it; there are certainly no books in which the student or the general practitioner can find such an excellent *résumé* of the literature of any topic, and such practical suggestions regarding the treatment of the various complications of every venereal disease. We take pleasure in repeating that we believe this to be the best treatise on venereal disease in the English language, and we congratulate the authors upon their brilliant addition to American medical literature.—*Chicago Med. Journal and Examiner*, February, 1880.

It is, without exception, the most valuable single work on all branches of the subject of which it treats in any language. The pathology is sound, the work is, at the same time, in the highest degree practical, and the hints that he will get from it for the management of any one case, at all obscure or obstinate, will more than repay him for the outlay.—*Archives of Medicine*, April, 1880.

This now classical work on venereal disease comes to us in its fourth edition rewritten, enlarged, and materially improved in every way. Dr. Taylor, as we had every reason to expect, has performed this part of his work with unusual excellence. We feel that what has been written has done but scanty justice to the merits of this truly great treatise.—*St. Louis Courier of Medicine*, Feb. 1880

We find that we have here practically a new book—that the statement of the title page, as to the fact that it has been largely rewritten, is a sufficiently modest announcement for the important changes in the text. After a thorough examination of the present edition, we can assert confidently that the enormous labor we have described has been here most faithfully and conscientiously performed.—*Amer. Journ. Med. Sci.*, Jan. 1880.

It is one of the best general treatises on venereal diseases with which we are acquainted, and is especially to be recommended as a guide to the treatment of syphilis.—*London Practitioner*, March, 1880.

CULLERIER (A.), Surgeon to the Hôpital du Midi. and *BUMSTEAD (FREEMAN J.), Professor of Venereal Diseases in the College of Physicians and Surgeons, N. Y.*

AN ATLAS OF VENEREAL DISEASES. Translated and Edited by

FREEMAN J. BUMSTEAD. In one large imperial 4to. volume of 328 pages, double-columns, with 26 plates, containing about 150 figures, beautifully colored, many of them the size of life; strongly bound in cloth, $17 00; also, in five parts, stout wrappers, at $3 per part.

Anticipating a very large sale for this work, it is offered at the very low price of THREE DOLLARS a Part, thus placing it within the reach of all who are interested in this department of practice. Gentlemen desiring early impressions of the plates would do well to order it without delay. A specimen of the plates and text sent free by mail, on receipt of 25 cents.

LEE'S LECTURES ON SYPHILIS AND SOME FORMS OF LOCAL DISEASE AFFECTING PRINCIPALLY THE ORGANS OF GENERATION. In one handsome octavo volume; cloth, $2 25.

HILL ON SYPHILIS AND LOCAL CONTAGIOUS DISORDERS. In one handsome octavo volume; cloth $3 25.

WEST (CHARLES), M.D.,

Physician to the Hospital for Sick Children, London, &c.

LECTURES ON THE DISEASES OF INFANCY AND CHILDHOOD.

Fifth American from the sixth revised and enlarged English edition. In one large and handsome octavo volume of 678 pages. Cloth, $4 50; leather, $5 50. (*Lately Issued.*)

BY THE SAME AUTHOR. (*Lately Issued.*)

ON SOME DISORDERS OF THE NERVOUS SYSTEM IN CHILDHOOD;

being the Lumleian Lectures delivered at the Royal College of Physicians of London, in March, 1871. In one volume small 12mo., cloth, $1 00.

BY THE SAME AUTHOR.

LECTURES ON THE DISEASES OF WOMEN.

Third American, from the Third London edition. In one neat octavo volume of about 550 pages, cloth, $3 75; leather, $4 75.

SMITH (*J. LEWIS*), *M.D.*,

Clinical Professor of Diseases of Children in the Bellevue Hospital Med. College, N. Y.

A COMPLETE PRACTICAL TREATISE ON THE DISEASES OF CHILDREN.

Fourth Edition, revised and enlarged. In one handsome octavo volume of about 750 pages, with illustrations. Cloth, $4 50; leather, $5 50; half Russia, $6. (*Now Ready.*)

The very marked favor with which this work has been received wherever the English language is spoken, has stimulated the author, in the preparation of the Fourth Edition, to spare no pains in the endeavor to render it worthy in every respect of a continuance of professional confidence. Many portions of the volume have been rewritten, and much new matter introduced, but by an earnest effort at condensation, the size of the work has not been materially increased.

In the period which has elapsed since the third edition of the work, so extensive have been the advances that whole chapters required to be rewritten, and hardly a page could pass without some material correction or addition. This labor has occupied the writer closely, and he has performed it conscientiously, so that the book may be considered a faithful portraiture of an exceptionally wide clinical experience in infantile diseases, corrected by a careful study of the recent literature of the subject.—*Med. and Surg. Reporter*, April 5, 1879.

It is scarcely necessary for us to say the work before us is a standard work upon diseases of children, and that no work has a higher standing than it upon these affections. In consequence of its thorough revision, the work has been made of more value than ever, and may be regarded as fully abreast of the times. We cordially commend it to students and physicians. There is no better work in the language on diseases of children.—*Cincinnati Med. News*, March, 1879.

The author has evidently determined that it shall not lose ground in the esteem of the profession for want of the latest knowledge on that important department of medicine. He has accordingly incorporated in the present edition the useful and practical results of the latest study and experience, both American and foreign, especially those bearing on therapeutics. Altogether the book has been greatly improved, while it has not been greatly increased in size.—*New York Medical Journal*, June, 1879.

This excellent work is so well known that an extended notice at this time would be superfluous. The author has taken advantage of the demand for another new edition to revise in a most careful manner the entire book; and the numerous corrections and additions evince a determination on his part to keep fully abreast with the rapid progress that is being made in the knowledge and treatment of children's diseases. By the adoption of a somewhat closer type, an increase in size of only thirty pages has been necessitated by the new subject matter introduced.—*Boston Med. and Surg. Jour.*, May 29, 1879.

Probably no other work ever published in this country upon a medical subject has reached such a height of popularity as has this well-known treatise. As a text and reference-book it is pre-eminently the authority upon diseases of children. It stands deservedly higher in the estimation of the profession than any other work upon the same subject.—*Nashville Journ. of Med. and Surg.*, May, 1879.

SWAYNE (*JOSEPH GRIFFITHS*), *M.D.*,

Physician-Accoucheur to the British General Hospital, &c.

OBSTETRIC APHORISMS FOR THE USE OF STUDENTS COMMENCING MIDWIFERY PRACTICE.

Second American, from the Fifth and Revised London Edition, with Additions by E. R. HUTCHINS, M.D. With Illustrations. In one neat 12mo. volume. Cloth, $1 25. (*Lately Issued.*)

*** See p. 3 of this Catalogue for the terms on which this work is offered as a premium to subscribers to the AMERICAN JOURNAL OF THE MEDICAL SCIENCES.

CHURCHILL ON THE PUERPERAL FEVER AND OTHER DISEASES PECULIAR TO WOMEN. 1 vol. 8vo., pp. 450, cloth. $2 50.

DEWEES'S TREATISE ON THE DISEASES OF FEMALES. With Illustrations. Eleventh Edition with the Author's last improvements and corrections. In one octavo volume of 536 pages, with plates, cloth. $3 00.

MEIGS ON THE NATURE, SIGNS, AND TREATMENT OF CHILDBED FEVER. 1 vol. 8vo., pp. 365, cloth. $2 00.

ASHWELL'S PRACTICAL TREATISE ON THE DISEASES PECULIAR TO WOMEN. Third American, from the Third and revised London edition. 1 vol. 8vo., pp. 528, cloth. $3 50.

HODGE (*HUGH L.*), *M.D.*,

Emeritus Professor of Obstetrics, &c., in the University of Pennsylvania.

ON DISEASES PECULIAR TO WOMEN; including Displacements of the Uterus.

With original illustrations. Second edition, revised and enlarged. In one beautifully printed octavo volume of 531 pages, cloth, $4 50.

CHURCHILL (*FLEETWOOD*), *M.D., M.R.I.A.*

ON THE THEORY AND PRACTICE OF MIDWIFERY.

A new American from the fourth revised and enlarged London edition. With notes and additions by D. FRANCIS CONDIE, M.D., author of a Practical Treatise on the Diseases of Children, &c. With one hundred and ninety-four illustrations. In one very handsome octavo volume of nearly 700 large pages. Cloth, $4 00; leather, $5 00.

MONTGOMERY'S EXPOSITION OF THE SIGNS AND SYMPTOMS OF PREGNANCY. With two exquisite colored plates, and numerous wood-cuts In 1 vol. 8vo., of nearly 600 pp., cloth, $3 75.

CONDIE'S PRACTICAL TREATISE ON THE DISEASES OF CHILDREN. Sixth edition, revised and augmented. In one large octavo volume of nearly 800 closely-printed pages, cloth, $5 25; leather, $6 25.

RIGBY'S SYSTEM OF MIDWIFERY. With notes and Additional Illustrations. Second American edition. One volume octavo, cloth, 422 pages, $2 50.

SMITH'S PRACTICAL TREATISE ON THE WASTING DISEASES OF INFANCY AND CHILDHOOD. Second American, from the second revised and enlarged English edition. In one handsome octavo volume, cloth, $2 50.

THOMAS (*T. GAILLARD*), *M.D.*,

Professor of Obstetrics, &c., in the College of Physicians and Surgeons, N. Y., &c.

A PRACTICAL TREATISE ON THE DISEASES OF WOMEN.

Fifth edition, thoroughly revised and rewritten. In one large and handsome octavo volume of over 800 pages, with 266 illustrations. Cloth, $5; leather, $6; very handsome half Russia, raised bands, $6 50. (*Just Ready.*)

The author has taken advantage of the opportunity afforded by the call for a new edition of this work to render it worthy a continuance of the very remarkable favor with which it has been received. Every portion of the work has been carefully revised, very much of it has been rewritten, and additions and alterations introduced wherever the advance of science and the increased experience of the author have shown them desirable. At the same time special care has been exercised to avoid undue increase in the size of the volume. To accommodate the numerous additions a more condensed but very clear letter has been used, notwithstanding which, the number of pages has been increased by more than fifty. The series of illustrations has been extensively changed; many which seemed to be superfluous have been omitted, and a large number of new and superior drawings have been inserted. In its improved form, therefore, it is hoped that the volume will maintain the character it has acquired of a standard authority on every detail of its important subject.

An examination of the work will satisfy that it is one of great merit. It is not a mere compilation from other works, but is the fruit of the ripe thought, sound judgment, and critical observations of a learned, scientific man. It is a treasury of knowledge of the department of medicine to which it is devoted. In its present revised state it certainly holds a foremost position as a gynæcological work, and will continue to be regarded as a standard authority.—*Cincinnati Med. News*, Dec. 1880.

This work needs no introduction to any of the civilized nations of the world. The edition before us adds to the strength of former volumes. With the wisdom of a master teacher he here gives the results that, in his judgment, are most trustworthy at the present time. In its own place it has no rival, because the author is the best teacher on this subject to the masses of the profession. As hitherto this work will be the text-book on diseases of women. We only wish that in other branches of medicine as capable teachers could be found to write our text-books.—*Detroit Lancet*, Jan 1881.

Since its first appearance, twelve years ago, until the present day, it has held a position of high regard, and is generally conceded to be one of the most practical and trustworthy volumes yet presented to the physician and student in the department of gynæcology. The work embodies not only its author's large experience, but reflects his careful study among other authorities in this branch, both at home and abroad. Dr. Thomas is an able and conscientious teacher. His writings convey his meaning in the same practical and instructive manner. The last edition of this work is fresh from his pen, with decided changes and improvements over former editions. His book presents generally accepted facts, and as a guide to the student is more useful and reliable than any work in the language on diseases of women. This last edition will add new laurels to those already won.—*Md. Med. Journ.*, Nov. 15, 1880.

It has been enlarged and carefully revised. The author has brought it fully abreast with the times, and as the wave of gynæcological progression has been widespread and rapid during the twelve years that have elapsed since the issue of the first edition, one can conceive of the great improvement this edition must be upon the earlier. It is a condensed encyclopædia of gynæcological medicine. The style of arrangement, the masterly manner in which each subject is treated, and the honest convictions derived from probably the largest clinical experience in that specialty of any in this country, all serve to commend it in the highest terms to the practitioner.—*Nashville Journ. of Med. and Surg.*, Jan. 1881.

BARNES (*ROBERT*), *M.D., F.R.C.P.*,

Obstetric Physician to St. Thomas's Hospital, &c.

A CLINICAL EXPOSITION OF THE MEDICAL AND SURGICAL DISEASES OF WOMEN.

Second American, from the Second Enlarged and Revised English Edition. In one handsome octavo volume, of 784 pages, with 181 illustrations. Cloth, $4 50; leather, $5 50; half Russia, $6. (*Just Issued.*)

Dr Barnes stands at the head of his profession in the old country, and it requires but scant scrutiny of his book to show that it has been sketched by a master. It is plain, practical common sense; shows very deep research without being pedantic; is eminently calculated to inspire enthusiasm without inculcating rashness; points out the dangers to be avoided as well as the success to be achieved in the various operations connected with this branch of medicine; and will do much to smooth the rugged path of the young gynæcologist and relieve the perplexity of the man of mature years.—*Canadian Journ. of Med. Science*, Nov. 1878.

We pity the doctor who, having any considerable practice in diseases of women, has no copy of "Barnes" for daily consultation and instruction. It is at once a book of great learning, research, and individual experience, and at the same time eminently practical. That it has been appreciated by the profession, both in Great Britain and in this country, is shown by the second edition following so soon upon the first.—*Am. Practitioner*, Nov. 1878.

Dr. Barnes's work is one of a practical character, largely illustrated from cases in his own experience, but by no means confined to such, as will be learned from the fact that he quotes from no less than 628 medical authors in numerous countries. Coming from such an author, it is not necessary to say that the work is a valuable one, and should be largely consulted by the profession.—*Am. Supp. Obstetrical Journ. Gt. Britain and Ireland*, Oct. 1878.

No other gynæcological work holds a higher position, having become an authority everywhere in diseases of women. The work has been brought fully abreast of present knowledge. Every practitioner of medicine should have it upon the shelves of his library, and the student will find it a superior text-book.—*Cincinnati Med. News*, Oct. 1878.

This second revised edition, of course, deserves all the commendation given to its predecessor, with the additional one that it appears to include all or nearly all the additions to our knowledge of its subject that have been made since the appearance of the first edition. The American references are, for an English work, especially full and appreciative, and we can cordially recommend the volume to American readers.—*Journ. of Nervous and Mental Disease*, Oct. 1878.

This second edition of Dr. Barnes's great work comes to us containing many additions and improvements which bring it up to date in every feature. The excellences of the work are too well known to require enumeration, and we hazard the prophecy that they will for many years maintain its high position as a standard text-book and guide-book for students and practitioners.—*N. C. Med. Journ.*, Oct. 1878.

EMMET (*THOMAS ADDIS*), *M.D.*,

Surgeon to the Woman's Hospital, New York, etc.

THE PRINCIPLES AND PRACTICE OF GYNÆCOLOGY, for the use of Students and Practitioners of Medicine. Second Edition. Thoroughly Revised. In one large and very handsome octavo volume of 875 pages, with 133 illustrations. Cloth, $5; leather, $6; half Russia, raised bands, $6 50. (*Just Ready.*)

PREFACE TO THE SECOND EDITION.

The unusually rapid exhaustion of a large edition of this work, while flattering to the author as an evidence that his labors have proved acceptable, has in a great measure heightened his sense of responsibility. He has therefore endeavored to take full advantage of the opportunity afforded to him for its revision. Every page has received his earnest scrutiny; the criticisms of his reviewers have been carefully weighed; and while no marked increase has been made in the size of the volume, several portions have been rewritten, and much new matter has been added. In this minute and thorough revision, the labor involved has been much greater than is perhaps apparent in the results, but it has been cheerfully expended in the hope of rendering the work more worthy of the favor which has been accorded to it by the profession.

In no country of the world has gynæcology received more attention than in America. It is, then, with a feeling of pleasure that we welcome a work on diseases of women from so eminent a gynæcologist as Dr. Emmet, and the work is essentially clinical, and leaves a strong impress of the author's individuality. To criticise, with the care it merits, the book throughout, would demand far more space than is at our command. In parting, we can say that the work teems with original ideas, fresh and valuable methods of practice, and is written in a clear and elegant style, worthy of the literary reputation of the country of Longfellow and Oliver Wendell Holmes.—*Brit. Med. Journ.* Feb. 21, 1880.

No gynæcological treatise has appeared which contains an equal amount of original and useful matter; nor does the medical and surgical history of America include a book more novel and useful. The tabular and statistical information which it contains is marvellous, both in quantity and accuracy, and cannot be otherwise than invaluable to future investigators. It is a work which demands not careless reading but profound study. Its value as a contribution to gynæcology is, perhaps, greater than that of all previous literature on the subject combined.—*Chicago Med. Gaz.*, April 5, 1880

The wide reputation of the author makes its publication an event in the gynæcological world; and a glance through its pages shows that it is a work to be studied with care. . . . It must always be a work to be carefully studied and frequently consulted by those who practise this branch of our profession.—*Lond. Med. Times and Gaz*, Jan. 10, 1880.

The character of the work is too well known to require extended notice—suffice it to say that no recent work upon any subject has attained such great popularity so rapidly. As a work of general reference upon the subject of Diseases of Women it is invaluable. As a record of the largest clinical experience and observation it has no equal. No physician who pretends to keep up with the advances of this department of medicine can afford to be without it.—*Nashville Journ. of Medicine and Surgery*, May, 1880.

DUNCAN (*J. MATTHEWS*), *M.D., LL.D., F.R.S.E., etc.*

CLINICAL LECTURES ON THE DISEASES OF WOMEN, Delivered in Saint Bartholomew's Hospital. In one very neat octavo volume of 173 pages. Cloth, $1 50. (*Just Ready.*)

They are in every way worthy of their author; indeed, we look upon them as among the most valuable of his contributions. They are all upon matters of great interest to the general practitioner. Some of them deal with subjects that are not, as a rule, adequately handled in the text-books; others of them, while bearing upon topics that are usually treated of at length in such works, yet bear such a stamp of individuality that, if widely read, as they certainly deserve to be, they cannot fail to exert a wholesome restraint upon the undue eagerness with which many young physicians seem bent upon following the wild teachings which so infest the gynæcology of the present day.—*N. Y. Med. Journ.*, March, 1880.

The author is a remarkably clear lecturer, and his discussion of symptoms and treatment is full and suggestive. It will be a work which will not fail to be read with benefit by practitioners as well as by students.—*Phila. Med. and Surg. Reporter*, Feb. 7, 1880.

We have read this book with a great deal of pleasure. It is full of good things. The hints on pathology and treatment scattered through the book are sound, trustworthy, and of great value. A healthy scepticism, a large experience, and a clear judgment are everywhere manifest. Instead of bristling with advice of doubtful value and unsound character, the book is in every respect a safe guide.—*The London Lancet*, Jan. 21, 1880.

RAMSBOTHAM (*FRANCIS H.*), *M.D.*

THE PRINCIPLES AND PRACTICE OF OBSTETRIC MEDICINE AND SURGERY, in reference to the Process of Parturition. A new and enlarged edition, thoroughly revised by the author. With additions by W. V. KEATING, M. D., Professor of Obstetrics, &c., in the Jefferson Medical College, Philadelphia. In one large and handsome imperial octavo volume of 660 pages, strongly bound in leather, with raised bands; with sixty-four beautiful plates, and numerous wood-cuts in the text, containing in all nearly 200 large and beautiful figures. $7 00

WINCKEL (*F.*),

Professor and Director of the Gynæcological Clinic in the University of Rostock.

A COMPLETE TREATISE ON THE PATHOLOGY AND TREATMENT OF CHILDBED, for Students and Practitioners. Translated, with the consent of the author, from the Second German Edition, by JAMES READ CHADWICK, M.D. In one octavo volume. Cloth, $4 00. (*Lately Issued.*)

TANNER (*THOMAS H.*), *M.D.*

ON THE SIGNS AND DISEASES OF PREGNANCY. First American from the Second and Enlarged English Edition. With four colored plates and illustrations on wood. In one handsome octavo volume of about 500 pages, cloth, $4 25.

LEISHMAN (*WILLIAM*), *M.D.*,

Regius Professor of Midwifery in the University of Glasgow, &c.

A SYSTEM OF MIDWIFERY, INCLUDING THE DISEASES OF PREGNANCY AND THE PUERPERAL STATE.

Third American edition, revised by the Author, with additions by JOHN S. PARRY, M.D., Obstetrician to the Philadelphia Hospital, &c. In one large and very handsome octavo volume, of 733 pages, with over two hundred illustrations. Cloth, $4 50; leather, $5 50; half Russia, $6. (*Just Ready.*)

Few works on this subject have met with as great a demand as this one appears to have. To judge by the frequency with which its author's views are quoted, and its statements referred to in obstetrical literature, one would judge that there are few physicians devoting much attention to obstetrics who are without it. The author is evidently a man of ripe experience and conservative views, and in no branch of medicine are these more valuable than in this.—*New Remedies*, Jan. 1880.

We gladly welcome the new edition of this excellent text-book of midwifery. The former editions have been most favorably received by the profession on both sides of the Atlantic In the preparation of the present edition the author has made such alterations as the progress of obstetrical science seems to require, and we cannot but admire the ability with which the task has been performed. We consider it an admirable text-book for students during their attendance upon lectures, and have great pleasure in recommending it. As an exponent of the midwifery of the present day it has no superior in the English language.—*Canada Lancet*, Jan. 1880.

To the American student the work before us must prove admirably adapted, complete in all its parts, essentially modern in its teachings and with demonstrations noted for clearness and precision, it will gain in favor and be recognized as a work of standard merit. The work cannot fail to be popular, and is cordially recommended.—*N. O. Med. and Surg. Journ.*, March, 1880.

Leishman's is certainly one of the best systematic works on midwifery. It is very complete in all the parts essential for such a treatise To practitioners and students it is to be strongly recommended as a safe and reliable guide to the modern practice of midwifery.—*Canada Med. and Surg. Journal*, March, 1880.

This is a book of well-established reputation, both in England and America. The present edition has been revised with care by the distinguished author, and supplied with such additions and emendations as the rapid advances in obstetrical science demand. *Pacific Med. and Surg. Journ.*, May, 1880.

The book is greatly improved, and as such will be welcomed by those who are trying to keep posted in the rapid advances which are being made in the study of obstetrics.—*Boston Med. and Surg. Journ.*, Nov 27, 1879.

This work is a thoroughly good one, and is well adapted to the requirements of the practical obstetrician. It is something more than a compend designed for the medical student: it is a book to be studied by the practitioner, and it will seldom disappoint him. It is of convenient size, clearly written, and eminently practical. As such, we heartily commend it to our readers —*St. Louis Clin. Record*, Jan. 1880.

We are glad to call the attention of our readers to this new edition of Dr. Leishman's well-known work, which has already established itself in general favor both in this country and in America. In noticing this third edition we need only direct attention to the differences between it and its predecessor. Although carefully revised throughout, with not a few additions in various places, the net enlargement amounts only to a few pages.—*Glasgow Med. Journ.*, Jan. 1880.

Leishman's is certainly one of the best systematic works on midwifery. It is very complete in all the parts essential for such a treatise. To practitioners and students it is to be strongly recommended as a safe and reliable guide to the modern practice of midwifery.—*Canada Med. and Surg. Journal*, March, 1880.

It has been well and carefully written. The views of the author are broad and liberal, and indicate a well balanced judgment and matured mind. We observe no spirit of dogmatism, but the earnest teaching of the thoughtful observer and lover of true science. Take the volume as a whole, and it has few equals.—*Md. Med. Journ.*, Feb. 1880.

Dr Leishman is too well known to the profession, not only that but to the student who is about to enter the profession, to need any introduction. Of his work, we need but say that it is a standard, sound and practical.—*St Louis Courier of Med.*, Jan. 1880.

PARRY (*JOHN S.*), *M.D.*,

Obstetrician to the Philadelphia Hospital, Vice-Pres. of the Obstet. Society of Philadelphia.

EXTRA-UTERINE PREGNANCY: ITS CLINICAL HISTORY, DIAGNOSIS, PROGNOSIS, AND TREATMENT.

In one handsome octavo volume. Cloth, $2 50. (*Lately Issued.*)

HODGE (*HUGH L.*), *M.D.*,

Emeritus Professor of Midwifery, &c., in the University of Pennsylvania, &c.

THE PRINCIPLES AND PRACTICE OF OBSTETRICS.

Illustrated with large lithographic plates containing one hundred and fifty-nine figures from original photographs, and with numerous wood-cuts. In one large and beautifully printed quarto volume of 550 double-columned pages, strongly bound in cloth. $14.

The work of Dr. Hodge is something more than a simple presentation of his particular views in the department of Obstetrics; it is something more than an ordinary treatise on midwifery; it is, in fact, a cyclopædia of midwifery. He has aimed to embody in a single volume the whole science and art of Obstetrics. An elaborate text is combined with accurate and varied pictorial illustrations, so that no fact or principle is left unstated or unexplained. —*Am. Med. Times*, Sept. 3, 1864.

*** Specimens of the plates and letter-press will be forwarded to any address, free by mail, on receipt of six cents in postage stamps.

CHADWICK (*JAMES R.*), *A.M.*, *M.D.*

A MANUAL OF THE DISEASES PECULIAR TO WOMEN.

In one neat volume, royal 12mo., with illustrations. (*Preparing.*)

PLAYFAIR (*W. S.*), *M.D., F.R.C.P.*,

Professor of Obstetric Medicine in King's College, etc. etc.

A TREATISE ON THE SCIENCE AND PRACTICE OF MIDWIFERY.

Third American edition, revised by the author. Edited, with additions, by ROBERT P. HARRIS, M.D. In one handsome octavo volume of about 700 pages, with nearly 200 illustrations. Cloth, $4; leather, $5; half Russia, $5 50. (*Just Ready*)

EXTRACT FROM THE AUTHOR'S PREFACE.

The second American edition of my work on Midwifery being exhausted before the corresponding English edition, I cannot better show my appreciation of the kind reception my book has received in the United States than by acceding to the publisher's request that I should myself undertake the issue of a third edition. As little more than a year has elapsed since the second edition was issued, there are naturally not many changes to make, but I have, nevertheless, subjected the entire work to careful revision, and introduced into it a notice of most of the more important recent additions to obstetric science. To the operation of gastro-elytrotomy—formerly described along with the Cæsarean section—I have now devoted a separate chapter. The editor of the Second American edition, Dr. Harris, enriched it with many valuable notes, of which, it will be observed, I have freely availed myself.

The medical profession has now the opportunity of adding to their stock of standard medical works one of the best volumes on midwifery ever published. The subject is taken up with a master hand. The part devoted to labor in all its various presentations, the management and results, is admirably arranged, and the views entertained will be found essentially modern, and the opinions expressed trustworthy. The work abounds with plates, illustrating various obstetrical positions; they are admirably wrought, and afford great assistance to the student.—*N. O. Med. and Surg. Journ.*, March, 1880.

If inquired of by a medical student what work on obstetrics we should recommend for him, as *par excellence*, we would undoubtedly advise him to choose Playfair's. It is of convenient size, but what is of chief importance, its treatment of the various subjects is concise and plain. While the discussions and descriptions are sufficiently elaborate to render a very intelligent idea of them, yet all details not necessary for a full understanding of the subject are omitted.—*Cincinnati Med. News*, Jan. 1880.

The rapidity with which one edition of this work follows another is proof alike of its excellence and of the estimate that the profession has formed of it. It is indeed so well known and so highly valued that nothing need be said of it as a whole. All things considered, we regard this treatise as the very best on Midwifery in the English language.—*N. Y. Medical Journal*, May, 1880

It certainly is an admirable exposition of the Science and Practice of Midwifery. Of course the additions made by the American editor, Dr. R. P. Harris, who never utters an idle word, and whose studious researches in some special departments of obstetrics are so well known to the profession, are of great value.—*The American Practitioner*, April, 1880.

BARNES (*FANCOURT*), *M.D.*,

Physician to the General Lying-in Hospital, London.

A MANUAL OF MIDWIFERY FOR MIDWIVES AND MEDICAL STUDENTS. With 50 illustrations. In one neat royal 12mo. volume of 200 pages; cloth, $1 25. (*Now Ready.*)

The book is written in plain, and as far as possible is unechnical language. Any intelligent midwife or medical student can easily comprehend the directions. It will undoubtedly fill a want, and will be popular with those for whom it has been prepared. The examining questions at the back will be found very useful.—*Cincinnati Med. News*, Aug. 1879.

STIMSON (*LEWIS A.*), *A.M., M.D.*,

Surgeon to the Presbyterian Hospital.

A MANUAL OF OPERATIVE SURGERY. In one very handsome royal 12mo. volume of about 500 pages, with 332 illustrations; cloth, $2 50. (*Just Issued.*)

The work before us is a well printed, profusely illustrated manual of over four hundred and seventy pages. The novice, by a perusal of the work, will gain a good idea of the general domain of operative surgery, while the practical surgeon has presented to him within a very concise and intelligible form the latest and most approved selections of operative procedure. The precision and conciseness with which the different operations are described enable the author to compress an immense amount of practical information in a very small compass.—*N. Y. Medical Record*, Aug. 3, 1878.

This volume is devoted entirely to operative surgery, and is intended to familiarize the student with the details of operations and the different modes of performing them. The work is handsomely illustrated, and the descriptions are clear and well drawn. It is a clever and useful volume; every student should possess one. The preparation of this work does away with the necessity of pondering over larger works on surgery for descriptions of operations, as it presents in a nut-shell just what is wanted by the surgeon without an elaborate search to find it.—*Md. Med Journal*, Aug. 1878.

The author's conciseness and the repleteness of the work with valuable illustrations entitle it to be classed with the text-books for students of operative surgery, and as one of reference to the practitioner. —*Cincinnati Lancet and Clinic*, July 27, 1878.

ERY'S OPERATIVE SURGERY. In 1 vol. 8vo. pl., of 660 pages; with about 100 wood-cuts. $3 25

OPER'S LECTURES ON THE PRINCIPLES AND PRACTICE OF SURGERY. In 1 vol. 8vo. cl'h, 750 p. $2.

BSON'S INSTITUTES AND PRACTICE OF SURGERY. Eighth edit'n, improved and altered. With thirty-four plates. In two handsome octavo volumes, about 1000 pp., leather, raised bands. $6 50.

E PRINCIPLES AND PRACTICE OF SURGERY By WILLIAM PIRRIE, F.R.S.E., Professor of Surgery in the University of Aberdeen. Edited by JOHN NEILL, M.D., Professor of Surgery in the Penna. Medical College, Surg'n to the Pennsylvania Hospital, &c. In one very handsome octavo vol. of 780 pages, with 316 illustrations, cloth, $3 75.

MILLER'S PRINCIPLES OF SURGERY. Fourth American, from the Third Edinburgh Edition. In one large 8vo. vol. of 700 pages, with 340 illustrations, cloth, $3 75.

MILLER'S PRACTICE OF SURGERY. Fourth American, from the last Edinburgh Edition Revised by the American editor. In one large 8vo. vol. of nearly 700 pages, with 364 illustrations: cloth, $3 75.

GROSS (*SAMUEL D.*), *M.D.*,

Professor of Surgery in the Jefferson Medical College of Philadelphia.

SYSTEM OF SURGERY: Pathological, Diagnostic, Therapeutic, and Operative. Illustrated by upwards of Fourteen Hundred Engravings. Fifth edition, carefully revised and improved. In two large and beautifully printed imperial octavo volumes of about 2300 pp., strongly bound in leather, with raised bands, $15; half Russia, raised bands, $16.

The continued favor, shown by the exhaustion of successive large editions of this great work, proves that it has successfully supplied a want felt by American practitioners and students. In the present revision no pains have been spared by the author to bring it in every respect fully up to the day. To effect this a large part of the work has been rewritten, and the whole enlarged by nearly one-fourth, notwithstanding which the price has been kept at its former very moderate rate. By the use of a close, though very legible type, an unusually large amount of matter is condensed in its pages, the two volumes containing as much as four or five ordinary octavos. This, combined with the most careful mechanical execution, and its very durable binding, renders it one of the cheapest works accessible to the profession. Every subject properly belonging to the domain of surgery is treated in detail, so that the student who possesses this work may be said to have in it a surgical library.

We have seldom read a work with the practical value of which we have been more impressed. Every chapter is so concisely put together, that the busy practitioner, when in difficulty, can at once find the information he requires. His work is cosmopolitan, the surgery of the world being fully represented in it. The work, in fact, is so historically unprejudiced, and so eminently practical, that it is almost a false compliment to say that we believe it to be destined to occupy a foremost place as a work of reference, while a system of surgery like the present system of surgery is the practice of surgeons. The printing and binding of the work is unexceptionable; indeed, it contrasts, in the latter respect, remarkably with English medical and surgical cloth-bound publications, which are generally so wretchedly stitched as to require re-binding before they are any time in use.—*Dub. Journ. of Med. Sci.*, March, 1874.

Dr. Gross's Surgery, a great work, has become still greater, both in size and merit, in its most recent form. The difference in actual number of pages is not more than 130, but, the size of the page having been increased to what we believe is technically termed "elephant," there has been room for considerable additions, which, together with the alterations, are improvements.—*Lond. Lancet*, Nov. 16, 1872.

It combines, as perfectly as possible, the qualities of a text-book and work of reference. We think this last edition of Gross's "Surgery," will confirm his title of "*Primus inter Pares.*" It is learned, scholar-like, methodical, precise, and exhaustive. We scarcely think any living man could write so complete and faultless a treatise, or comprehend more solid, instructive matter in the given number of pages. The labor must have been immense, and the work gives evidence of great powers of mind, and the highest order of intellectual discipline and methodical disposition and arrangement of acquired knowledge and personal experience.—*N. Y. Med. Journ.*, Feb 1873.

As a whole, we regard the work as the representative "System of Surgery" in the English language.—*St. Louis Medical and Surg. Journ.*, Oct. 1872.

The two magnificent volumes before us afford a very complete view of the surgical knowledge of the day. Some years ago we had the pleasure of presenting the first edition of Gross's Surgery to the profession as a work of unrivalled excellence; and now we have the result of years of experience, labor, and study, all condensed upon the great work before us. And to students or practitioners desirous of enriching their library with a treasure of reference, we can simply commend the purchase of these two volumes of immense research.—*Cincinnati Lancet and Observer*, Sept. 1872.

A complete system of surgery—not a mere text-book of operations, but a scientific account of surgical theory and practice in all its departments.—*Brit. and For. Med. Chir. Rev.*, Jan. 1873.

BY THE SAME AUTHOR.

A PRACTICAL TREATISE ON THE DISEASES, INJURIES, and Malformations of the Urinary Bladder, the Prostate Gland, and the Urethra. Third Edition, thoroughly Revised and Condensed, by SAMUEL W. GROSS, M.D., Surgeon to the Philadelphia Hospital. In one handsome octavo volume of 574 pages, with 170 illustrations: cloth, $4 50. (*Just Issued.*)

For reference and general information, the physician or surgeon can find no work that meets their necessities more thoroughly than this, a revised edition of an excellent treatise, and no medical library should be without it. Replete with handsome illustrations and good ideas, it has the unusual advantage of being easily comprehended, by the reasonable and practical manner in which the various subjects are systematized and arranged. We heartily recommend it to the profession as a valuable addition to the important literature of diseases of the urinary organs.—*Atlanta Med. Journ.*, Oct. 1876.

It is with pleasure we now again take up this old work in a decidedly new dress. Indeed, it must be regarded as a new book in very many of its parts. The chapters on "Diseases of the Bladder," "Prostate Body," and "Lithotomy," are splendid specimens of descriptive writing; while the chapter on "Stricture" is one of the most concise and clear that we have ever read.—*New York Med. Journ.*, Nov. 1876.

BY THE SAME AUTHOR.

A PRACTICAL TREATISE ON FOREIGN BODIES IN THE AIR-PASSAGES. In 1 vol. 8vo., with illustrations, pp. 468, cloth, $2 75.

DRUITT (*ROBERT*), *M.R.C.S., &c.*

THE PRINCIPLES AND PRACTICE OF MODERN SURGERY.

A new and revised American, from the eighth enlarged and improved London edition. Illustrated with four hundred and thirty-two wood engravings. In one very handsome octavo volume, of nearly 700 large and closely printed pages, cloth, $4 00; leather, $5 00.

All that the surgical student or practitioner could desire.—*Dublin Quarterly Journal.*

It is a most admirable book. We do not know when we have examined one with more pleasure.—*Boston Med. and Surg. Journal.*

In Mr. Druitt's book, though containing only some seven hundred pages, both the principles and the practice of surgery are treated, and so clearly and perspicuously, as to elucidate every important topic. We have examined the book most thoroughly, and can say that this success is well merited. His book, moreover, possesses the inestimable advantages of having the subjects perfectly well arranged and classified and of being written in a style at once clear and succinct.—*Am. Journal of Med. Sciences.*

HAMILTON (FRANK H.) M.D., LL.D.,

Surgeon to the Bellevue Hospital, New York.

A PRACTICAL TREATISE ON FRACTURES AND DISLOCATIONS

Sixth edition, thoroughly revised, and much improved. In one very handsome octavo volume of over 900 pages, with 352 Illustrations. Cloth, $5 50; leather, $6.50; half Russia; raised bands, $7 00.

The demand which has so speedily exhausted five large editions of this work, shows that the author has succeeded in supplying a want, felt by the profession at large, of an exhaustive treatise on a frequent and troublesome class of accidents. The unanimous voice of the profession abroad, as well as at home, has pronounced it the most complete work to which the surgeon can refer for information respecting the details of the subject. In the preparation of this new edition, the author has added a chapter on General Prognosis: that on Fractures of the Patella has been entirely rewritten, in order that the results of a recent exhaustive study of this subject might be given, and, in fact, the entire matter of the book has undergone most thorough revision. A number of illustrations have been omitted to make place for new ones, and a few have been inserted from the German edition, published at Göttingen in 1877.

So many kind expressions of welcome have been showered upon each successive edition of this valuable treatise, that scarcely anything remains for us to do but to extend the customary cordial greeting. It is the only complete work on the subject of Fractures in the English language. We congratulate the accomplished author on the deserved success of his work, and hope that he may live to have many succeeding editions pass under his skilled supervision.—*Phila. Coll. and Clin. Record*, Nov. 15, 1880.

Dr Hamilton has devoted great labor to the study of these subjects. His large experience, extended research and patient investigation have made him one of the highest authorities among living writers in this branch of surgery. This work is systematic and practical in its arrangement, and presents its subject matter clearly and forcibly to the reader or student.—*Maryland Medical Journal*, Nov. 15, 1880.

The only complete work on its subject in the English tongue, and, indeed, may now be said to be the only work of its kind in any tongue. It would require an exceedingly critical examination to detect in it any particulars in which it might be improved. The work is a monument to American surgery, and will long serve to keep green the memory of its venerable author.—*Michigan Med. News*, Nov. 10, 1880.

Universal verdict has pronounced it, humanly speaking, a perfect treatise upon this subject. As it is the only complete and illustrated work in any language treating of fractures and dislocations, it is safe to affirm that every wide-awake surgeon and general practitioner will regard it as indispensable to the safe and pleasant conduct of their professional work.—*Detroit Lancet*, Nov. 18, 1880.

The book is known to be the only complete treatise in the English language, or in any language, and needs no recommendation. If there should still be a surgeon who does not have the book in his library, we advise him to get it immediately.—*Buffalo Med. and Surg. Journ.*, Dec. 1880

This is the sixth edition of the only work extant devoted exclusively to fractures and dislocations. That no ambitious surgeon has aspired to enter this field as a rival to Prof. Hamilton is ample testimony to the thoroughness and completeness with which he has done his work.—*Ohio Med. Recorder*, Dec. 1880.

ASHHURST (JOHN, Jr.), M.D.,

Prof. of Clinical Surgery, Univ of Pa., Surgeon to the Episcopal Hospital, Philadelphia.

THE PRINCIPLES AND PRACTICE OF SURGERY.

Second edition, enlarged and revised. In one very large and handsome octavo volume of over 1000 pages, with 542 illustrations. Cloth, $6; leather, $7; half Russia, $7.50. (*Just Ready.*)

Conscientiousness and thoroughness are two very marked traits of character in the author of this book. Out of these traits largely has grown the success of his mental fruit in the past, and the present offer seems in no wise an exception to what has gone before. The general arrangement of the volume is the same as in the first edition, but every part has been carefully revised, and much new matter added.—*Phila. Med. Times*, Feb. 1, 1879.

We have previously spoken of Dr. Ashhurst's work in terms of praise. We wish to reiterate those terms here, and to add that no more satisfactory representation of modern surgery has yet fallen from the press. In point of judicial fairness, of power of condensation, of accuracy and conciseness of expression and thoroughly good English, Prof. Ashhurst has no superior among the surgical writers in America.—*Am. Practitioner*, Jan. 1879.

The attempt to embrace in a volume of 1000 pages the whole field of surgery, general and special, would be a hopeless task unless through the most tireless industry in collating and arranging, and the wisest judgment in condensing and excluding. These facilities have been abundantly employed by the author, and he has given us a most excellent treatise, brought up by the revision for the second edition to the latest date. Of course this book is not designed for specialists, but as a course of general surgical knowledge and for general practitioners, and as a text-book for students it is not surpassed by any that has yet appeared, whether of home or foreign authorship.—*N. Carolina Med. Journal*, Jan. 1879.

The favorable reception of the first edition is a guarantee of the popularity of this edition, which is fresh from the editor's hands with many enlargements and improvements. The author of this work is deservedly popular as an editor and writer, and his contributions to the literature of surgery have gained for him wide reputation. The volume now offered the profession will add new laurels to those already won by previous contributions. We can only add that the work is well arranged, filled with practical matter, and contains in brief and clear language all that is necessary to be learned by the student of surgery whilst in attendance upon lectures, or the general practitioner in his daily routine practice.—*Md. Med. Journal*, Jan. 1879.

The fact that this work has reached a second edition so very soon after the publication of the first one, speaks more highly of its merits than anything we might say in the way of commendation. It seems to have immediately gained the favor of students and physicians.—*Cincin. Med. News*, Jan. '79.

ASHTON ON THE DISEASES, INJURIES, AND MALFORMATIONS OF THE RECTUM AND ANUS: with remarks on Habitual Constipation. Second American, from the fourth and enlarged London Edition. With illustrations. In one 8vo. vol. of 237 pages, cloth, $2 25.

SARGENT ON BANDAGING AND OTHER OPERATIONS OF MINOR SURGERY. New edition, with an additional chapter on Military Surgery. One 12mo. vol. of 383 pages with 184 wood-cuts Cloth, $1 75.

BRYANT (*THOMAS*), *F.R.C.S.*,

Surgeon to Guy's Hospital.

THE PRACTICE OF SURGERY. Third American, from the Second and Revised English Edition. Thoroughly revised and much improved, by John B. Roberts, M.D. In one large and very handsome imperial octavo volume of over 1000 pages, with 672 illustrations. Cloth, $6 50; leather, $7 50; very handsome half Russia, raised bands, $8 00. (*Just Ready.*)

Mr. Bryant's work has long been a favorite one with surgeons. As its name indicates, it is of a thoroughly practical character. It is distinctly individual in that it gives the results of the author's large and varied experience as an operator and clinical teacher, and is on that account prized deservedly high as an original work. The style is necessarily condensed, the descriptions of surgical diseases brief and to the point. The illustrations are well chosen, and the typical cases of the author's experience are full of interest, and are of more than ordinary value to the working surgeon.—*N. Y. Medical Record*, March 5, 1881.

It is a work especially adapted to the wants of students and practitioners. While not prolix, it affords instruction in sufficient detail for a full understanding of surgical principles and the treatment of surgical diseases. It embraces in its scope all the diseases that are recognized as belonging to surgery, and all traumatic injuries. In discussing these it has seemed to be the aim of the author rather to present the student with practical information, and that alone, than to burden his memory with the views of different writers, however distinguished they might have been. In this edition the whole work has been carefully revised, much of it has been rewritten, important additions have been made to almost every chapter.—*Cincinnati Med. News*, Jan. 1881.

The English edition, from which this is printed, has been carefully revised and rewritten; almost every chapter has received additions, and nearly one hundred new cuts introduced. The labors of the American editor, Dr. John B. Roberts, have very much increased the value of the book. He has introduced many new illustrations and much new material not found in the English edition. He has written too with great conciseness, which is a rare virtue in an American editor of an English work. If one could procure or wished only one surgery, this volume would certainly be selected. If he desired two, Erichsen's Surgery would be added, and if he wished a third, Gross's Surgery would justly be the work selected. As the great work of Gross is amply sufficient for the wants of any surgeon, the priority given to Erichsen, and above all others, to this work of Bryant, is no labored eulogy of the last volume, but a simple and just statement of its demonstrable and pre-eminent merits.—*Am. Med. Bi-Weekly*, Feb. 26, 1881.

ERICHSEN (*JOHN E.*),

Professor of Surgery in University College, London, etc.

THE SCIENCE AND ART OF SURGERY; being a Treatise on Surgical Injuries, Diseases, and Operations. Carefully revised by the author from the Seventh and enlarged English Edition. Illustrated by eight hundred and sixty two engravings on wood. In two large and beautiful octavo volumes of nearly 2000 pages: cloth, $8 50; leather, $10 50; half Russia, $11 50. (*Now Ready.*)

Of the many treatises on Surgery which it has been our task to study, or our pleasure to read, there is none which in all points has satisfied us so well as the classic treatise of Erichsen. His polished, clear style, his freedom from prejudice and hobbies, his unsurpassed grasp of his subject, and vast clinical experience, qualify him admirably to write a model text-book. When we wish, at the least cost of time, to learn the most of a topic in surgery, we turn, by preference, to his work. It is a pleasure, therefore, to see that the appreciation of it is general, and has led to the appearance of another edition.—*Med. and Surg. Reporter*, Feb. 2, 1878.

Notwithstanding the increase in size, we observe that much old matter has been omitted. The entire work has been thoroughly written up, and not merely amended by a few extra chapters. A great improvement has been made in the illustrations. One hundred and fifty new ones have been added, and many of the old ones have been redrawn. The author highly appreciates the favor with which his work has been received by American surgeons, and has endeavored to render his latest edition more than ever worthy of their approval. That he has succeeded admirably, must, we think, be the general opinion. We heartily recommend the book to both student and practitioner.—*N. Y. Med. Journal* Feb. 1878.

The seventh edition is before the world as the last word of surgical science. There may be monographs which excel it upon certain points, but as a conspectus upon surgical principles and practice it is unrivalled. It will well reward practitioners to read it, for it has been a peculiar province of Mr. Erichsen to demonstrate the absolute interdependence of medical and surgical science. We need scarcely add, in conclusion, that we heartily commend the work to students that they may be grounded in a sound faith, and to practitioners as an invaluable guide at the bedside.—*Am. Practitioner*, April, 1878.

For the past twenty years Erichsen's Surgery has maintained its place as the leading text-book, not only in this country, but in Great Britain. That it is able to hold its ground, is abundantly proven by the thoroughness with which the present edition has been revised, and by the large amount of valuable material that has been added. Aside from this, one hundred and fifty new illustrations have been inserted, including quite a number of microscopical appearances of pathological processes. So marked is this change for the better that the work almost appears as an entirely new one.—*Med. Record*, Feb. 23, 1878.

HOLMES (*TIMOTHY*), *M.D.*,

Surgeon to St. George's Hospital, London.

SURGERY, ITS PRINCIPLES AND PRACTICE. In one handsome octavo volume of nearly 1000 pages, with 411 illustrations. Cloth, $6; leather, $7; half Russia, $7 50. (*Just Issued.*)

This is a work which has been looked for on both sides of the Atlantic with much interest. Mr. Holmes is a surgeon of large and varied experience, and one of the best known, and perhaps the most brilliant writer upon surgical subjects in England. It is a book for students—and an admirable one—and for the busy general practitioner. It will give a student all the knowledge needed to pass a rigid examination. The book fairly justifies the high expectations that were formed of it. Its style is clear and forcible, even brilliant at times, and the conciseness needed to bring it within its proper limits has not impaired its force and distinctness.—*N. Y. Med. Record*, April 14, 1876.

It will be found a most excellent epitome of surgery by the general practitioner who has not the time to give attention to more minute and extended works and to the medical student. In fact, we know of no one we can more cordially recommend. The author has succeeded well in giving a plain and practical account of each surgical injury and disease, and of the treatment which is most commonly advisable. It will no doubt become a popular work in the profession, and especially as a text-book.—*Cincinnati Med. News*, April, 1876.

WELLS (*J. SOELBERG*),
Professor of Ophthalmology in King's College Hospital, &c.

A TREATISE ON DISEASES OF THE EYE. Third American, from the Third London Edition. Thoroughly revised, with copious additions, by Chas. S. Bull, M D., Surgeon and Pathologist to the New York Eye and Ear Infirmary. Illustrated with about 250 engravings on wood, and six colored plates. Together with selections from the Test-types of Jaeger and Snellen. In one large and very handsome octavo volume of 900 pages. Cloth, $5; leather, $6; half Russia, raised bands, $6.50. (*Just Ready.*)

The long-continued illness of the author, with its fatal termination, has kept this work for some time out of print, and has deprived it of the advantage of the revision which he sought to give it during the last years of his life. This edition has therefore been placed under the editorial supervision of Dr. Bull, who has labored earnestly to introduce in it all the advances which observation and experience have acquired for the theory and practice of ophthalmology since the appearance of the last revision. To accomplish this, considerable additions have been required, and the work is now presented in the confidence that it will fully deserve a continuance of the very marked favor with which it has hitherto been greeted as a complete, but concise, exposition of the principles and facts of its important department of medical science.

The additions made in the previous American editions by Dr. Hays have been retained, including the very full series of illustrations and the test-types of Jaeger and Snellen.

This new edition of Dr. Wells's great work on the eye will be welcomed by the profession at large as well as by the oculist. It contains much new matter relating to treatment and pathology, and is brought thoroughly up with the present status of ophthalmology. Its chapter on refraction and accommodation—a subject much discussed of late years, and of great importance—is exceedingly complete.—*Louisville Med. News*, Nov. 13, 1880.

The merits of Wells's treatise on diseases of the eye have been so universally acknowledged, and are so familiar to all who profess to have given any attention to ophthalmic surgery, that any discussion of them at this late day will be a work of supererogation. Very little that is practically useful in recent ophthalmic literature has escaped the editor, and the third American edition is well up to the times. As a text-book on ophthalmic surgery for the English-speaking practitioner, it is without a rival.—*Am. Journ. of Med. Sci.*, Jan. 1881.

The work has justly held a high place in English ophthalmic literature, and at the time of its first appearance was the best treatise of its kind in the language. In the second edition, the author showed industrious research in adding new material from every quarter, and his spirit was eminently candid. A work thus built up by honest effort should not be suffered to die, and we are pleased to receive this third edition from the hands of Dr. Bull. His labor has been arduous, as the very great number of additions bracketed with his initial testify. Under the editorship which the third edition has enjoyed, the work is sure to sustain its good reputation, and to maintain its usefulness.—*N. Y. Med. Journ.*, Jan. 1881.

There is really no work which approaches it in adaptation to the wants of the general practitioner, while the most advanced specialist cannot rise from a perusal of its ample pages without having added to his knowledge. The American editor, Dr. Bull, won his spurs in ophthalmology some time back. His additions to the work of the lamented Wells are many, judicious, and timely, and in just so much have added to its value.—*Am. Practitioner*, Jan. 1881.

NETTLESHIP (*EDWARD*), *F.R.C.S.*,
Ophthalmic Surg. and Lect. on Ophth. Surg. at St. Thomas' Hospital, London.

MANUAL OF OPHTHALMIC MEDICINE. In one royal 12mo. volume of over 350 pages, with 89 illustrations. Cloth, $2. (*Just Ready.*)

The author is to be congratulated upon the very successful manner in which he has accomplished his task; he has succeeded in being concise without sacrificing clearness, and, including the whole ground covered by more voluminous text-books, has given an excellent *résumé* of all the practical information they contain. We do not hesitate to pronounce Mr Nettleship's book the best manual on ophthalmic surgery for the use of students and "busy practitioners" with which we are acquainted.—*Am. Jour. Med. Sciences*, April, 1880.

CARTER (*R. BRUDENELL*), *F.R.C.S.*,
Ophthalmic Surgeon to St. George's Hospital, etc.

A PRACTICAL TREATISE ON DISEASES OF THE EYE. Edited, with test-types and Additions, by JOHN GREEN, M.D. (of St. Louis, Mo.). In one handsome octavo volume of about 500 pages, and 124 illustrations. Cloth, $3 75. (*Just Issued.*)

It is with great pleasure that we can endorse the work as a most valuable contribution to practical ophthalmology. Mr. Carter never deviates from the end he has in view, and presents the subject in a clear and concise manner, easy of comprehension, and hence the more valuable. We would especially commend, however, as worthy of high praise, the manner in which the therapeutics of disease of the eye is elaborated, for here the author is particularly clear and practical, where other writers are unfortunately too often deficient. The final chapter is devoted to a discussion of the uses and selection of spectacles, and is admirably compact, plain, and useful, especially the paragraphs on the treatment of presbyopia and myopia. In conclusion, our thanks are due the author for many useful hints in the great subject of ophthalmic surgery and therapeutics, a field where of late years we glean but a few grains of sound wheat from a mass of chaff.—*New York Medical Record*, Oct. 23, 1875.

BROWNE (*EDGAR A.*),
Surgeon to the Liverpool Eye and Ear Infirmary, and to the Dispensary for Skin Diseases.

HOW TO USE THE OPHTHALMOSCOPE. Being Elementary Instructions in Ophthalmoscopy, arranged for the Use of Students. With thirty-five illustrations. In one small volume royal 12mo. of 120 pages: cloth, $1. (*Now Ready.*)

LAURENCE'S HANDY-BOOK OF OPHTHALMIC SURGERY, for the use of Practitioners. Second edition, revised and enlarged. With numerous illustrations. In one very handsome octavo volume, cloth, $2 75.

LAWSON'S INJURIES TO THE EYE, ORBIT, AND EYELIDS: their Immediate and Remote Effects. With about one hundred illustrations. In one very handsome octavo volume, cloth, $3 50.

BURNETT (CHARLES H.), M.A., M.D.,

Aural Surg to the Presb. Hosp., Surgeon-in-charge of the Infir. for Dis. of the Ear, Phila.

THE EAR, ITS ANATOMY, PHYSIOLOGY, AND DISEASES.

A Practical Treatise for the Use of Medical Students and Practitioners. In one handsome octavo volume of 615 pages, with eighty-seven illustrations: cloth, $4 50; leather, $5 50; half Russia, $6 00. (*Now Ready.*)

Foremost among the numerous recent contributions to aural literature will be ranked this work of Dr. Burnett. It is impossible to do justice to this volume of over 600 pages in a necessarily brief notice. It must suffice to add that the book is profusely and accurately illustrated, the references are conscientiously acknowledged, while the result has been to produce a treatise which will henceforth rank with the classic writings of Wilde and Von Tröltsch.—*The Lond. Practitioner*, May, 1879.

On account of the great advances which have been made of late years in otology, and of the increased interest manifested in it, the medical profession will welcome this new work, which presents clearly and concisely its present aspect, whilst clearly indicating the direction in which further researches can be most profitably carried on. Dr. Burnett from his own matured experience, and availing himself of the observations and discoveries of others, has produced a work which, as a text-book, stands *facile princeps* in our language. We had marked several passages as well worthy of quotation and the attention of the general practitioner, but their number and the space at our command forbid. Perhaps it is better, as the book ought to be in the hands of every medical student, and its study will well repay the busy practitioner in the pleasure he will derive from the agreeable style in which many otherwise dry and mostly unknown subjects are treated. To the specialist the work is of the highest value, and his sense of gratitude to Dr. Burnett will, we hope, be proportionate to the amount of benefit he can obtain from the careful study of the book, and a constant reference to its trustworthy pages.—*Edinb. Jl Med. Jour.*, Aug. 1878.

TAYLOR (ALFRED S.), M.D.,

Lecturer on Med. Jurisp. and Chemistry in Guy's Hospital.

A MANUAL OF MEDICAL JURISPRUDENCE.

Eighth American edition. Thoroughly revised and rewritten. Edited by JOHN J. REESE, M.D., Prof. of Med. Jurisp. and Toxicology in the Univ. of Penn. In one large octavo volume of 933 pages. Cloth, $5; leather, $6; half Russia, raised bands, $6 50. (*Just Ready*)

The American editions of this standard manual have for a long time laid claim to the attention of the profession in this country; and that the profession has recognized this claim with favor is proven by the call for frequent new editions of the work. This one, the eighth, comes before us as embodying the latest thoughts and emendations of Dr. Taylor, upon the subject to which he devoted his life, with an assiduity and success which made him *facile princeps* among English writers on medical jurisprudence. Both the author and the book have made a mark too deep to be affected by criticism, whether it be censure or praise. In this case, however, we should only have to seek for laudatory terms.—*Am. Journ. of Med. Sci.*, Jan. 1881.

It is not very often that a medical book reaches its tenth edition, or that the last earthly labor is performed by the author in retouching the work that first came from his hand thirty-five years before. All this, however, has happened in the case of Dr. Taylor and his classical treatise. The pen dropped from the grasp only when the shadows of old age were rapidly deepening into the darkness of death. Under the circumstances, all the journalist has to do is to announce, not criticise the completed task. The value of the gem is too well known to require more than the telling that the master-hand has retouched its facets and polished its angles before leaving it as his legacy to his brethren in the profession.—*Phila. Med. Times*, Dec. 4, 1880.

It will suffice to remark that this new edition shows the signs of judicious revision. A great number of illustrative medico-legal cases which have occurred since the last edition was published are cited in their proper connection, and add much to the interest and value of the work; they comprise the bulk of the additions to the text. As an indication of the freshness of the work, we notice numerous references to medico-legal experience that has transpired during the year just ended; among these is a comment by the American editor upon that midsummer madness, the Tanner fasting exploit of last August. In these features and in others there is ample evidence that this admirable book will maintain its high place as a standard authority concerning the matters of which it treats.—*Boston Med. and Surg. Journal*, Jan. 13, 1881.

BY THE SAME AUTHOR.

THE PRINCIPLES AND PRACTICE OF MEDICAL JURISPRUDENCE.

Second Edition, Revised, with numerous Illustrations. In two large octavo volumes, cloth, $10 00; leather, $12 00

This great work is now recognised in England as the fullest and most authoritative treatise on every department of its important subject. In laying it, in its improved form, before the American profession, the publishers trust that it will assume the same position in this country.

BY THE SAME AUTHOR.

POISONS IN RELATION TO MEDICAL JURISPRUDENCE AND MEDICINE.

Third American, from the Third and Revised English Edition. In one large octavo volume of 850 pages; cloth, $5 50; leather, $6 50. (*Just Issued.*)

The present is based upon the two previous editions; "but the complete revision rendered necessary by time has converted it into a new work." This statement from the preface contains all that it is desired to know in reference to the new edition. The works of this author are already in the library of every physician who is liable to be called upon for medico-legal testimony (and what one is not), so that all that is required to be known about the present book is that the author has kept it abreast with the times. What makes it now, as always, especially valuable to the practitioner is its conciseness and practical character, only those poisonous substances being described which give rise to legal investigations.—*The Clinic*, Nov. 6, 1875.

Dr. Taylor has brought to bear on the compilation of this volume, stores of learning, experience, and practical acquaintance with his subject, probably far beyond what any other living authority on toxicology could have amassed or utilized. He has fully sustained his reputation by the consummate skill and legal acumen he has displayed in the arrangement of the subject-matter, and the result is a work on Poisons which will be indispensable to every student or practitioner in law and medicine.—*The Dublin Journ. of Med Sci.*, Oct. 1875.

ROBERTS (*WILLIAM*), *M.D.*,
Lecturer on Medicine in the Manchester School of Medicine, etc.

A PRACTICAL TREATISE ON URINARY AND RENAL DISEASES, including Urinary Deposits. Illustrated by numerous cases and engravings. Third American, from the Third Revised and Enlarged London Edition. In one large and handsome octavo volume of over 600 pages. Cloth, $4. (*Just Ready.*)

THOMPSON (*SIR HENRY*),
Surgeon and Professor of Clinical Surgery to University College Hospital.

LECTURES ON DISEASES OF THE URINARY ORGANS. With illustrations on wood. Second American from the Third English Edition. In one neat octavo volume. Cloth, $2 25. (*Just Issued.*)

BY THE SAME AUTHOR.

ON THE PATHOLOGY AND TREATMENT OF STRICTURE OF THE URETHRA AND URINARY FISTULÆ. With plates and wood-cuts. From the third and revised English edition. In one very handsome octavo volume, cloth, $3 50. (*Lately Published.*)

TUKE (*DANIEL HACK*), *M.D.*,
Joint author of The Manual of Psychological Medicine, &c.

ILLUSTRATIONS OF THE INFLUENCE OF THE MIND UPON THE BODY IN HEALTH AND DISEASE. Designed to illustrate the Action of the Imagination. In one handsome octavo volume of 416 pages, cloth, $3 25. (*Lately Issued.*)

BLANDFORD (*G. FIELDING*), *M.D., F.R.C.P.*,
Lecturer on Psychological Medicine at the School of St. George's Hospital, &c.

INSANITY AND ITS TREATMENT: Lectures on the Treatment, Medical and Legal, of Insane Patients. With a Summary of the Laws in force in the United States on the Confinement of the Insane. By ISAAC RAY, M. D. In one very handsome octavo volume of 471 pages; cloth, $3 25.

It satisfies a want which must have been sorely felt by the busy general practitioners of this country. It takes the form of a manual of clinical description of the various forms of insanity, with a description of the mode of examining persons suspected of insanity. We call particular attention to this feature of the book, as giving it a unique value to the general practitioner. If we pass from theoretical considerations to descriptions of the varieties of insanity as actually seen in practice and the appropriate treatment for them, we find in Dr. Blandford's work a considerable advance over previous writings on the subject. His pictures of the various forms of mental disease are so clear and good that no reader can fail to be struck with their superiority to those given in ordinary manuals in the English language or (so far as our own reading extends) in any other.—*London Practitioner*, Feb. 1871.

LEA (*HENRY C.*).

SUPERSTITION AND FORCE: ESSAYS ON THE WAGER OF LAW, THE WAGER OF BATTLE, THE ORDEAL, AND TORTURE. Third Revised and Enlarged Edition. In one handsome royal 12mo. volume of 552 pages. Cloth, $2 50. (*Just Ready.*)

This valuable work is in reality a history of civilization as interpreted by the progress of jurisprudence. . . . In "Superstition and Force" we have a philosophic survey of the long period intervening between primitive barbarity and civilized enlightenment. There is not a chapter in the work that should not be most carefully studied, and however well versed the reader may be in the science of jurisprudence, he will find much in Mr. Lea's volume of which he was previously ignorant. The book is a valuable addition to the literature of social science.—*Westminster Review*, Jan. 1880.

The appearance of a new edition of Mr. Henry C. Lea's "Superstition and Force" is a sign that our highest scholarship is not without honor in its native country. Mr. Lea has met every fresh demand for his work with a careful revision of it, and the present edition is not only fuller and, if possible, more accurate than either of the preceding, but, from the thorough elaboration, is more like a harmonious concert and less like a batch of studies.—*The Nation*, Aug. 1, 1878.

Many will be tempted to say that this, like the "Decline and Fall," is one of the uncriticizable books. Its facts are innumerable, its deductions simple and inevitable, and its *chevaux-de-frise* of references bristling and dense enough to make the keenest, stoutest, and best equipped assailant think twice before advancing. Nor is there anything controversial in it to provoke assault. The author is no polemic. Though he obviously feels and thinks strongly, he succeeds in attaining impartiality. Whether looked on as a picture or a mirror, a work such as this has a lasting value.—*Lippincott's Magazine*, Oct. 1878.

BY THE SAME AUTHOR.

STUDIES IN CHURCH HISTORY. THE RISE OF THE TEMPORAL POWER—BENEFIT OF CLERGY—EXCOMMUNICATION. In one large royal 12mo. volume of 516 pp.; cloth, $2 75. (*Lately Published.*)

The story was never told more calmly or with greater learning or wiser thought. We doubt, indeed, if any other study of this field can be compared with this for clearness, accuracy, and power.—*Chicago Examiner*, Dec. 1870.

Mr. Lea's latest work, "Studies in Church History," fully sustains the promise of the first. It deals with three subjects—the Temporal Power, Benefit of Clergy, and Excommunication, the record of which has a peculiar importance for the English student, and is a chapter on Ancient Law likely to be regarded as final. We can hardly pass from our mention of such works as these—with which that on "Sacerdotal Celibacy" should be included—without noting the literary phenomenon that the head of one of the first American houses is also the writer of some of its most original books.—*London Athenæum*, Jan. 7, 1871.

HENRY C. LEA'S SON & CO.—Philadelphia.

GREEN'S PATHOLOGY—New Edition—Just Ready.

PATHOLOGY AND MORBID ANATOMY. By T. Henry Green, M.D., Lecturer on Pathology and Morbid Anatomy, at Charing Cross Medical School, London. Fourth American, from the Fifth enlarged and thoroughly revised English edition. In one handsome octavo volume of 350 pages, with 138 fine engravings. Cloth, $2 25.

We have long considered this the best guide yet presented to the student for the identification of various morbid tissues. We have found it more satisfactory than any other. The present edition has been thoroughly revised, and much new matter has been added. To the physician as a guide in diagnosis, we recommend this volume.—*Physician and Surgeon*, May, 1881.

CLOWES' CHEMISTRY—New Edition—Just Ready.

AN ELEMENTARY TREATISE ON PRACTICAL CHEMISTRY AND QUALITATIVE INORGANIC ANALYSIS. By Frank Clowes, D.Sc. London, Senior Science Master at the High School, Newcastle-under-Lyme. Specially adapted for use in the Laboratories of Schools and Colleges, and by Beginners. Second American, from the third and revised English edition, with about 50 illustrations on wood. In one very handsome royal 12mo. volume of 372 pages. Cloth, $2 50.

Of all the various works on chemistry designed for students this, to our mind, is far the best. The language is simple, unnecessary scientific terms being avoided. The directions how to work, the preparation and use of apparatus, and the thorough instruction in laboratory work, render the work in every way intelligible to the student. The work embraces all that is really necessary, and the author has evidently avoided farther detail. On account of its simplicity and thoroughness, it certainly deserves a place in every student's library, however limited.—*N. Y. Med. Gazette*, March 5, 1881.

FLINT'S PRACTICE—New Edition—Just Ready.

A TREATISE ON THE PRINCIPLES AND PRACTICE OF MEDICINE; Designed for the use of Students and Practitioners of Medicine. By Austin Flint, M.D., Professor of the Principles and Practice of Medicine in Bellevue Med. College, N. Y. Fifth edition, thoroughly revised and much improved. In one large and closely printed octavo volume of 1153 pages. Cloth, $5 50; leather, $6 50; very handsome half Russia, raised bands, $7.

Its predominant good sense is one of the qualities which have caused Dr. Flint's treatise to be so highly esteemed; and as the present edition has all the merits of the earlier ones, and, in addition, a large amount of scientific as distinguished from clinical information which was less conspicuous in them, it cannot fail to confirm and increase the reputation of the work which they established. In a word, we do not know of any similar work which is at once so elaborate and so concise, so full and yet so accurate; or which in every part leaves upon the mind the impression of its being the product of an author richly stored with the fruits of clinical observation, and an adept in the art of conveying them clearly and attractively to others.—*Amer. Journ. Med. Sci.*, April, 1881.

With a view to meeting the requirements of the day the author has rather rewritten than revised his work. Beyond the evident care with which numerous authorities have been consulted, together with its conspicuous clearness and precision of style, the work commends itself by a certain spirit of conservatism and strong common sense which is eminently characteristic of all the author's writings.—*N. Y. Med. Journ.*, May, 1881.

THOMAS ON WOMEN—New and Revised Edition—Just Ready.

A PRACTICAL TREATISE ON THE DISEASES OF WOMEN. By T. Gaillard Thomas, M.D., Prof. of Obstetrics, etc., in the College of Physicians and Surgeons, New York. Fifth edition, thoroughly revised and rewritten. In one large and handsome 8vo. vol. of 810 pages, with 266 illustrations. Cloth, $5; leather, $6; very handsome half Russia, raised bands, $6 50.

By common consent Prof. Thomas's work ranks as, all things considered, the best text-book of gynæcology ever written. The work is so well known and highly esteemed that we need do but little more than point out the more noticeable of the new matter in this new edition. Besides the careful revision to which the whole has evidently been subjected, we notice a new chapter on general considerations upon Uterine Pathology and Treatment, one on Congenital and Infantile Malformations, one on Uterine Fungosities, one on Laceration of the Cervix, one on Oöphorectomy, and one on Extra-uterine Pregnancy, together with a section on Adenoma of the Uterus. We would repeat that as a whole, the work is most admirable, and we would commend to the reader even those parts of it in which, as we believe, there is some error.—*N. Y. Med. Journ.*, March, 1881.

HAMILTON ON FRACTURES—New Edition—Just Ready.

A PRACTICAL TREATISE ON FRACTURES AND DISLOCATIONS. By Frank H. Hamilton, M.D., LL.D., Surgeon to Bellevue Hospital, New York, etc. Sixth edition, thoroughly revised and much improved. In one very handsome octavo volume of 900 pages, with 352 illustrations. Cloth, $5 50; leather, $6 50; very handsome half Russia, raised bands, $7.

A formal review of Prof. Hamilton's classical work is scarcely called for at the present day. This edition, besides being carefully revised, has in part been entirely rewritten—for instance, the chapter on fractures of the patella; and a chapter on general prognosis has been added. The work, as a whole, is one of the very few medical books of American origin that are everywhere accorded a standard character. Its subject-matter unavoidably comes home to every general practitioner, as a branch of our art in which he cannot afford to neglect the fullest and most practical information of just such a character as it and it alone furnishes. —*N. Y. Med. Journal*, March, 1881.

BURNETT ON THE EAR—Lately Issued.

THE EAR; ITS ANATOMY, PHYSIOLOGY AND DISEASES. A Practical Treatise for the use of Medical Students and Practitioners. By Charles H. Burnett, A.M., M.D., Aural Surg. to the Presb. Hospital; Surg. in Charge of the Infirmary for Diseases of the Ear, Phila. In one handsome octavo volume of 615 pages, with 87 illustrations. Cloth, $4 50; leather, $5 50; very handsome half Russia, raised bands, $6.

HENRY C. LEA'S SON & CO.—Philadelphia.

PROSPECTUS FOR 1881.

THE AMERICAN JOURNAL OF THE MEDICAL SCIENCES.

In commencing its sixty-first year, the publishers of the "AMERICAN JOURNAL OF THE MEDICAL SCIENCES" have much pleasure in assuring its wide circle of readers that at no period has it had the prospect of a more extended field of usefulness.

For 1881 the "American Journal" has the promise of its usual variety of important contributions from distinguished members of the profession in all parts of the country. Special attention will be bestowed, as heretofore, on its Bibliographical Department and Quarterly Summaries to keep its subscribers informed as to all subjects of professional interest from every quarter.

With its attendant periodical, "THE MEDICAL NEWS AND ABSTRACT," it combines the advantages of the elaborate preparation which can be given to a quarterly, and the prompt conveyance of intelligence by the monthly, while, the whole being under a single editorial supervision, the subscriber is secured against the duplication of matter inevitable under other circumstances. These efforts the publishers seek to second by offering these periodicals at a price unprecedentedly low—a price which places them within the reach of every practitioner, and gives the equivalent of three large octavo volumes for the comparatively trifling cost of FIVE DOLLARS *per annum*.

The "NEWS AND ABSTRACT" consists of sixty-four pages monthly, in a neat cover. It contains a CLINICAL DEPARTMENT in which will be continued the series of ORIGINAL AMERICAN CLINICAL LECTURES, contributed by gentlemen of the highest reputation throughout the United States, together with a choice selection of Foreign Lectures and Hospital Notes and Gleanings. Then follows the "MONTHLY ABSTRACT," systematically arranged and classified, and presenting five or six hundred articles yearly; each number concluding with an EDITORIAL and a NEWS DEPARTMENT, giving current professional intelligence, domestic and foreign, the whole fully indexed at the close of each volume, rendering it of permanent value for reference.

The subscription price to the "NEWS AND ABSTRACT" will be Two Dollars and a Half per annum, invariably in advance, at which rate it will rank as one of the cheapest medical periodicals in the country. But it will also be furnished, free of all charge, in commutation with the "AMERICAN JOURNAL OF THE MEDICAL SCIENCES," to all who remit FIVE DOLLARS in advance, thus giving to the subscriber, for that very moderate sum, a complete record of medical progress throughout the world, in the compass of about two thousand large octavo pages.

These terms may be recapitulated as follows:—

TERMS FOR 1881.

The AMERICAN JOURNAL OF THE MEDICAL SCIENCES, published quarterly (1150 pages per annum), and The MEDICAL NEWS AND ABSTRACT, published monthly (768 pages per annum),	Five Dollars per annum, in advance.

SEPARATE SUBSCRIPTIONS TO

The AMERICAN JOURNAL OF THE MEDICAL SCIENCES, when not paid for in advance,	Five Dollars.
The MEDICAL NEWS AND ABSTRACT, invariably in advance,	Two Dollars and a Half.

*** Advance-paying subscribers can obtain, at the close of the year, cloth covers, gilt lettered, for binding the volumes of the JOURNAL (two annually) and the NEWS AND ABSTRACT (one annually), free by mail, on remitting ten cents for each cover.

The safest mode of remittance is by bank check or draft, or postal money order drawn to the order of the undersigned. Where these are not accessible, remittances for the "JOURNAL" and "NEWS AND ABSTRACT" may be made at the risk of the publishers by forwarding in REGISTERED letters.

PHILADELPHIA:
HENRY C. LEA'S SON & CO.
1881.

PUBLISHED MONTHLY AT $2.50 PER ANNUM IN ADVANCE.
Furnished in conjunction with the Quarterly American Journal of the Medical Sciences (in all nearly 2000 octavo pages) for $5.00 in advance.

Entered according to the Act of Congress, in the year 1881, by HENRY C. LEA'S SON & CO., in the Office of the Librarian of Congress. All rights reserved.

SOLD ONLY BY SUBSCRIPTION.

REYNOLDS'S SYSTEM OF MEDICINE—Revised Edition--Just Ready.

A SYSTEM OF MEDICINE.

EDITED BY J. RUSSELL REYNOLDS, M.D.,

Prof. of the Principles and Practice of Medicine in University College, London.

WITH NOTES AND ADDITIONS

BY HENRY HARTSHORNE, M.D.,

Late Professor of Hygiene in the University of Pennsylvania.

In three large and handsome royal octavo volumes, containing 3052 *closely printed double column pages, with* 351 *illustrations.*

PRICES.

	Cloth.	Sheep.	Half Russia.
Per volume	$5 00	$6.00	$6.50
Per set	15.00	18.00	19.50

VOLUME I. contains GENERAL DISEASES and DISEASES OF THE NERVOUS SYSTEM.

VOLUME II. contains DISEASES OF THE RESPIRATORY and CIRCULATORY SYSTEMS.

VOLUME III. contains DISEASES OF THE DIGESTIVE and BLOOD GLANDULAR SYSTEMS, OF THE URINARY ORGANS, OF THE FEMALE REPRODUCTIVE SYSTEM and OF THE CUTANEOUS SYSTEM.

Reynolds's System, as a work of reference in medicine, is unexcelled and unequalled, and should be in the library of every physician. Dr. Hartshorne, the American editor, has contributed articles on cholera morbus, cholera infantum, trichina spiralis, bronchocele, pernicious anæmia, and spermatorrhœa, besides making such additions to many other articles as the progress of medical science since the volumes first appeared, required. The task he undertook has been well performed, and the thanks of all Amer can physicians are due to the American editor for affording them the opportunity of obtaining at a reasonable price such a magnificent cyclopædia of the practice of medicine, embodying as it does the views of the most learned members of the medical profession of Great Britain. We earnestly advise all our readers to buy the volumes and *read them.*—*Canadian Journ. of Med. Sci.*, Oct. 1880.

It gives us pleasure to recommend most cordially this System of Medicine, not merely to the student but also to the busy practitioner of medicine.—*Amer. Journ. of Med. Sciences*, Aug. 1880.

Reynolds's System of Medicine is a work so full in detail, yet so exclusively practical in character, that it is indispensable as a work of reference for every practising physician. It is more nearly a cyclopædia of practical medicine than any other work with which we are familiar. In the reprint before us the entire text of the English edition has been preserved except in the case of some very elaborate tables, fully elucidated in the text, while much has been added chiefly in the form of entirely new articles on subjects not treated in the English edition. For the production of this great cyclopædic treatise, the profession owes Dr. Hartshorne, the American editor, an everlasting debt of gratitude.—*Louisville Med. Herald*, Aug. 1880.

As a work of reference, Reynolds's System of Medicine is the most thorough and complete in the English language. Each subject has assigned it a distinct author, whose special merits are fully and clearly put before the reader. We know of no work whose value so appeals to the wants of the profession and so important to the practitioner.—*Southern Medical Record*, Nov. 20, 1880.

Regarding the work as a whole, we give it our earnest commendation. It places within the reach of the average physician a series of monographs, written by some of the most eminent men of the age, upon an extremely wide range of subjects. It is the latest and best cyclopædic work on practical medicine written in our language.—*St. Louis Clinical Record*, Aug. 1880.

Valuable as the work was when issued in England, the labors of Dr. Hartshorne have added very greatly to its worth, and it can now but be regarded as the best encyclopædia of medicine extant.—*American Practitioner*, Aug. 1880.

These three ponderous volumes contain a vast amount of valuable information; as works of reference in the library of the discriminating practitioner, the medical investigator, and the medical teacher, they are of real value.—*Chicago Med. Journ. and Examiner*, Aug. 1880.

In style, economy of space clearness and brevity; in comprehensiveness, excellence of description, and practical utility, it is admirable.—*Chicago Med. Rev.*, July 20, 1880.

As a treatise on the Practice of Medicine, the three volumes constituting this series are incomparable. Compendious in detail, and scientific in description, it can but eventually take the first place among present standard works on this subject.—*Atlanta Med. and Surg. Journ.*, Oct. 1880.

These three volumes are a whole library in and of themselves. As works of reference they are destined to be for many years regarded as the very highest authority on medical subjects. Language is scarcely adequate to express the actual value to general practitioners of such a system of medicine as this of Professor Reynolds.—*Cincinnati Lancet and Clinic*, Aug. 21, 1880.

It will be observed with pleasure by the medical profession generally, that an American edition is now given us of this great English classical work on Practice of Medicine. Reynolds' work is regarded as *the* one to which we must look for an exposition of the ideas and teachings of the best English medical minds of the present day. This edition of a work which is one of the very best in the English language, constitutes an important addition to medical literature, and is every way worthy of the great publishing house from which it issues.—*Canada Medical and Surgical Journal*, April, 1880.

Clinical Lectures.

ON ATYPICAL TYPHOID FEVER.

A CLINICAL LECTURE DELIVERED AT THE PHILADELPHIA HOSPITAL,

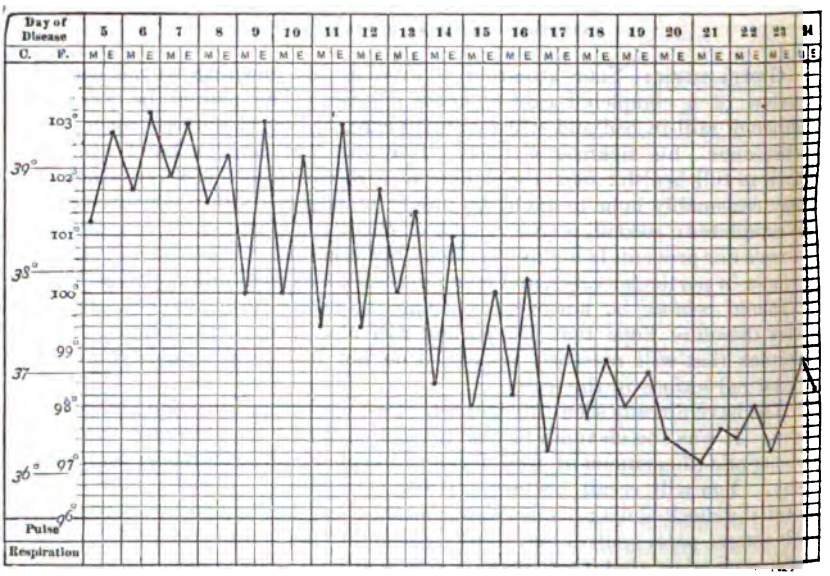
BY JAMES C. WILSON, M.D.,

ATTENDING PHYSICIAN TO THE HOSPITAL.

GENTLEMEN: Your attention is invited this morning to the careful review of a completed case of acute disease. The patient before you, although still in bed and still requiring care, has fairly entered upon convalescence—his sickness is over. Two principal dangers beset his way back to full health: first, the danger of a recrudescence of fever—this we may reasonably hope to avoid by proper management until convalescence is completed; second, a true relapse of the disease, which we can neither foresee nor prevent, being as yet altogether ignorant of the cause of typhoid relapse in particular cases, and much in the dark as to its etiology in general. Typhoid relapse is, however, of comparatively rare occurrence, and we may therefore hope that our patient will also escape this danger. For reasons that will presently appear, I do not fear local trouble from the intestinal lesions in this case.

You have already seen this patient. Two weeks ago I brought him before you. It was the eleventh day of his sickness, and he presented the characteristic phenomena of well-developed typhoid fever of moderate intensity. You will recall his face, listless, apathetic, pale, with a faint flush over the cheek bones; his deafness, and the slow, dull manner of his replies; his tongue pale, coated, and trembling slightly as it was protruded. You will remember that there were a few scattered loud râles heard upon auscultation of the lungs, that there was diarrhœa amounting to three or four loose stools in the twenty-four hours, slight tympany without either tenderness or gurgling, and that there were scattered over the anterior surface of the chest and abdomen some lenticular rose spots which faded upon pressure and at once reappeared upon the removal of the pressure. These spots were first seen on the fifth day after admission, or the ninth of the attack. I was enabled to demonstrate an extended area of splenic dulness. You will readily call to mind the elevated temperature and its range, for it was to these that our joint attention was chiefly directed.

The absolute temperature was not high, and the range between the evening and morning, the maximum and minimum of the diurnal cycle, was considerable, amounting to a full degree of the Fahrenheit scale during the first three days the patient had been under observation, and to nearly three degrees afterward, the evening temperature only once exceeding, by a fifth of a degree, 103° F. The investigations of Wunderlich long ago brought to light the fact that, as a rule, in uncomplicated typhoid fever the temperature during the whole course of the attack rarely exceeds the maximum attained at the close of the first or the beginning of the second week (or period). It is further well known that a temperature-range characterized by considerable morning remissions is much less injurious to the tissues, even when the evening maxima are relatively higher, than a continuous or subcontinuous fever. The consideration of these two facts, together with the absence of symptoms indicating either excessive constitutional action of the fever-poison (zymosis), or extensive or severe local lesions, led me to predict with some degree of confidence a favourable course for the attack. The prognosis has proved to have been correct. The temperature at no period after the evening of the day upon which you saw the case rose above 103° F. On the contrary, it steadily but slowly declined until the night of the sixteenth day, when it fell more than three degrees, from 100.2° to 97°, and it has since that date varied but



little from the normal. The patient no longer presents the symptoms of typhoid fever. He is pale, but his expression is neither languid nor listless. The flush has disappeared; he hears well, and replies to my questions promptly and with interest. We learn from him that the statements made by those who brought him to the hospital were in the main correct. He is a cellar-digger, 40 years of age, married, temperate, and of previous good health. Whilst at work four days before admission, he was *suddenly*

seized with chills, which recurred several times in the course of the day; there was severe frontal headache and disinclination to take food; at night he had fever and pains in his joints. The next day he was unable to go to work. I desire to call your attention especially to the fact that up to the day of the chills he had felt nothing amiss, but had worked as usual, and thought himself well. From his manner of replying it is clear that he is intelligent and that his memory is good. The râles are no longer heard, the tympany and spots have disappeared, diarrhœa has given place to slight constipation with formed stools, and the area of splenic dulness has diminished. About the thirteenth and fourteenth days there was slight pulmonary hypostasis; epistaxis did not occur, and there was no delirium. Two or three new spots appeared on the fifteenth day. Albuminuria did not occur.

Aside from the moderate severity of the symptoms in this case, in which respect it certainly stands forth in striking contrast to the examples of typhoid fever that are usually shown you in this theatre, your attention at once fixes itself upon three facts in the history, that are not in accord with the picture of the typical disease, as you have found it correctly drawn for you in the text-books, or vividly portrayed in the lecture-room, or have commonly seen it in the clinic, the wards, or in your own practice. These are, first, the abruptness of the onset; second, the short duration of the sickness, defervescence being complete upon the seventeenth day; and third, the comparative abruptness of the defervescence.

Great as are the variations from the ordinary type which this case presents in its origin, its course, and its termination, the symptom-grouping makes it clear beyond all doubt that we have had to do with an example of typhoid fever. This being established, the questions at once arise: To what group of the forms of typhoid is this case to be properly referred? And what are the departures from the common pathological conditions of typhoid fever by which to explain these conspicuous variations from the usual course of the disease?

In order to reply to these questions it is necessary to revert to a convenient nosological arrangement to which the various forms of disease due to the typhoid poison may be referred, and to briefly consider the influences by which the action of the poison is so modified as to produce well-marked and more or less constant variations in its clinical manifestations.

All cases may be referred to one or the other of two comprehensive groups:—

A. The typical.
B. The atypical.

A. The typical, or perfect, or common form is too familiar to require in this connection a word of description. Its insidious beginning, its prolonged duration, its gradual defervescence and tardy convalescence are as well known to you as is its unmistakable symptom-grouping. That different cases of such a disease should present variations in the prominence of certain symptoms or groups of symptoms, is quite in accordance with our experience in all diseases both acute and chronic. These variations are due, on the one hand, to differences in the relative degree of intensity of the action of the cause upon the fluids of the body at large, or upon the lymphatic system of the ileum; and, on the other, to differences in individuals as regards bodily constitution, temperament, previous condition of health, and so forth. Notable variations arise also in consequence of the presence of complications. But clearly apparent through all such variations is the

conformity to type, which sets forth the nature of the disease and renders the diagnosis a comparatively easy task. It is this conformity to type that renders subdivisions of this group unnecessary, and the discrimination of such forms as *bilious, nervous, ataxic, adynamic,* or *cerebral, thoracic,* and *abdominal,* not only useless, but positively misleading both in the lecture-room and at the bedside.

It is important to bear in mind that the fever in the typical cases, like that of scarlet fever and of smallpox, is made up of two distinct febrile movements—first, a primary fever, resulting from the infection of the tissues of the body by the specific virus; and later, a secondary, irritative or hectic fever, caused by the localized ulceration in the intestines, the formation of slough, and the resorption of septic materials.

B. The atypical or imperfect forms are much more rare, and present difficulties in their clinical study proportionate to their want of the very conformity to type that renders the investigation of the cases belonging to the first group relatively a simple matter. So great is this want of conformity to type in many of the atypical cases of typhoid fever, that they are not to be recognized by their clinical manifestations, but only in the light of a common etiological relation to well-developed cases occurring in more or less extended (local) epidemics. This statement is true of most epidemic diseases. Side by side with well-developed cases are seen imperfect, slight, or abortive cases manifestly due to the prevalent epidemic influence, but so faintly marked as to be recognizable only in the light of that influence.

The second comprehensive group must, from this point of view, be subdivided into a number of forms, which may be arranged in order, according to the degree of their departure from the typical disease. These forms are:—

a. Mild typhoid (including walking typhoid).
b. Abortive typhoid.
c. Typhoid of childhood (so-called infantile remittent).
d. Typhoid of the aged.
e. Cases of febrile intestinal catarrh.
f. Cases of afebrile intestinal catarrh.

These atypical or imperfect forms constitute, in most epidemics, a large proportion of the cases, and they will be found, I believe, to be much more common where the disease is endemic than has usually been thought, when the attention of physicians is more closely turned to the study of typhoid fever from an etiological as well as from a clinical standpoint. The modifications which characterize such cases are partly due to mild infection, or the smallness of the dose of the fever-producing principle; partly to an imperfect susceptibility on the part of the patient, and partly to differences in the reaction of the organism to the fever-poison and the products of unduly rapid waste at different periods of life.

a. The mild cases present the symptoms of the typical disease modified in respect of intensity, and in particular is this true of the febrile movement, which is of a lower grade. The commencement of the attack is usually gradual; there are prodromes, which pass step by step into the declared disease. Chilly sensations may occur; a decided chill is unusual. There is headache, diarrhœa; the nose may bleed, and the eruption may or may not appear. The temperature may reach upon the fourth or fifth day 104° F., but it rarely exceeds that point, and much more commonly

does not attain it. The temperature-range corresponds to that of the typical form, save that upon corresponding days it is a degree or more lower. The duration of this form may be four full weeks; it is perhaps oftener less than this, each of the four periods not exceeding four or five days. The febrile movement corresponds to the primary and the secondary fever of the fully developed disease. The intestinal lesions do not undergo resolution, but go on to sloughing.

The latent, or ambulatory form (*walking typhoid*) belongs to this group. In this form all the symptoms are at first mild; the disease shows itself in general malaise, prostration, and elevation of temperature, yet the sickness extends over three or four weeks, and the intestinal lesion proceeds to sloughing and ulceration. Herein lies the danger of this form of the disease. The patient regards himself as suffering from some slight indisposition, a "cold," or a "bilious attack," and continues to go about in a wretched way, or even, if he be a person of determined will, to attend to his ordinary occupations, and to eat such food as his appetite permits, until sudden delirium reveals to his friends the serious character of his illness, a profuse hemorrhage occurs, or, and this is still more common, symptoms of perforation supervene, and are followed, after a few hours, by death.

b. The abortive form appears to be not uncommon in Europe. In this country it is certainly rare. The attack begins abruptly; prodromes are usually of short duration, or they may be absent altogether. The temperature-range is, at first, that of the typical disease, save that it in some instances more rapidly attains its maximum. The invasion is often accompanied by rigors, sometimes by a decided chill. There is usually moderate diarrhœa; tympany, enlargement of the spleen, sometimes epistaxis, and often more or less bronchial catarrh. The characteristic eruption is frequently observed, and transient albuminuria is met with. Some time in the second week or early in the third, the sickness takes a sudden turn, and runs a similar course as regards ordinary typhoid fever, to that which varioloid runs as regards vario a.

The defervescence is rapid, often being completed in from twenty-four to seventy-two hours, and is frequently attended by profuse sweating. Convalescence is also rapid. It is in the highest degree probable that in these cases the intestinal lesions undergo resolution, their evolution being arrested short of the ordinary necrotic processes. We, therefore, have to do with the primary fever due to the action of the special poison, and not with the secondary or septic fever due to ulceration and the formation of sloughs. The parallelism between these cases as compared with typical typhoid fever, and varioloid as compared with variola, is complete.

c. The term infantile remittent fever has been applied to typhoid fever as it occurs in children, for the reason that the pyrexia often assumes in them a distinctly remittent type throughout the whole course of the attack. The symptoms and complications are modified by the age of the patient. Children are very susceptible to typhoid.

d. In the advanced periods of life typhoid fever is rare. When it occurs, it runs a modified course. Its onset is insidious, the febrile movement is less intense than at earlier periods of life, and the temperature often falls during convalescence to markedly subnormal ranges. There is especial danger of collapse. Acute delirium is not so common, and diarrhœa is less apt to be urgent. The characteristic eruption is rarely observed.

e. In rare instances a slight disturbance of the functions of the body results from the infection, and gives rise to intestinal catarrh with eleva-

tion of temperature so slight and so irregular that it scarcely deserves the name of fever (100.4° F.).

f. Finally it may be stated upon the authority of Liebermeister and Dr. Cayley, that intestinal catarrh occasionally occurs in consequence of typhoid infection, in which there is no elevation of temperature at all.

It is evident that the case which occupies our attention to-day must be referred to the second of the subdivisions of the atypical forms of typhoid fever. The sudden onsent of the attack, the rapid temperature-rise, which nearly attained its maximum upon the evening of the fifth day, the short duration of the whole sickness, and the abrupt fall of the temperature during the night of the sixteenth day, are characteristic of that form of typhoid fever properly called "abortive."

The sudden onset of the attack has been established by a careful cross-examination of the patient and his friends. The fact that the headache, still present when he came under observation, spontaneously ceased four days later, and that the eruption was first discovered on the fifth day after admission, the ninth of the attack, confirm this statement. For, as you well know, the eruption of typhoid usually appears at the close of the first or early in the second week, and the headache commonly ceases spontaneously about the tenth day.

The whole course of the attack has probably comprised only the primary fever due to the constitutional action of the typhoid-poison. For some reason unknown to us the intestinal lesions have undergone resolution without sloughing, and our patient has escaped the secondary or septic fever, which in the typical disease overlaps the primary febrile movement at its close, and prolongs the sickness with well-marked remissions and with a gradual defervescence to the end of the third or fourth week. It is for this reason that I do not especially fear trouble from the intestinal lesions during the convalescence in this patient.

The treatment has had no influence whatever in abridging the course of the attack. It has been practically expectant. The patient was kept at rest, not being allowed to rise for any purpose; he was from time to time sponged with cold water, for purposes of cleanliness rather than with any view of acting upon the temperature; his diet was regulated *secundum artem*. Of medicines, he took upon the first day a little calomel, afterwards at short intervals a draught containing compound tincture of cinchona with dilute muriatic acid, flavoured with syrup of orange-peel.

CASE OF INTRAMURAL FIBROID TUMOUR OF THE UTERUS.

A Clinical Lecture delivered at the Middlesex Hospital.

By HENRY MORRIS, M.A., F.R.C.S.,
Surgeon to the Hospital.

Gentlemen: Elizabeth B., aged 32, single, an upholsteress, was admitted on October 26, 1880, for complete retention of urine. Her usual medical attendant, Dr. Ayling, sent her to me with a letter to the effect that, on May 20, 1880, he was summoned, and found her suffering great agony from not having micturated for nineteen hours. He introduced the catheter, and drew off over three pints of urine. Next day, catheterization had to be repeated. She then went on for a week before the catheter was next required; then she continued well for three

months before she again required help. Of late, it had become necessary to pass the catheter twice daily; and as she had suffered acute pain at times about the pelvis, calculus or some other serious affection of the bladder suggested itself.

On admission, there was complete inability to micturate, so that the catheter had to be used at regular intervals. The urine was acid, of specific gravity 1015, and free from blood and albumen. She was anæmic, of a dark complexion and nervous temperament, with twitchings of the face when spoken to, and an hysterical look and manner. Her general health had been good; but she had had much mental trouble of late, and to this she attributed her illness. When I examined her on October 28th, at 2 P. M., though her urine had been drawn off at 8 A. M., her bladder was distended, and formed a large prominent ovoid abdominal swelling to the right of the middle line, and inclining very obliquely outwards and upwards. In the left iliac fossa there were marked fulness, dulness, and increased resistance, quite distinct from the abdominal tumour formed by the bladder, and suggesting the presence of a solid or tense cystic tumour of rounded outline. A male catheter was easily introduced, and passed a long way before urine began to flow; the catheter took a very oblique course, and it was found possible to introduce it, without resistance, so far into the bladder that the bone ferrule was hidden by the vulva. The bladder being emptied, an examination *per vaginam* was made; but, as a fairly perfect hymen existed, a satisfactory exploration of the pelvis could not be effected without causing pain. It was ascertained, however, that the vagina was markedly inclined to the left, but that its wall was projected on the right side for a short distance upwards, so that the idea of a bifid vagina was for a moment suggested to the mind of the examiner. The uterus was so much drawn up, and to the left side, that at this examination the os and cervix were not felt. The rectum was found flattened by a smooth, round, hard, unyielding tumour in front, which did not feel like the os or enlarged fundus of the uterus. The mass was clearly inclined to the left side, whether examined with the patient on the back or on the side. A simple enema was ordered to be given every morning. Subsequently (October 30th and November 2d) she was seen by Dr. Hall Davis, who found the uterus considerably drawn up, the os being felt as a mere depression close to the upper border of the symphysis pubis; and the uterine sound passed for four and three-quarter inches into the cavity of the uterus.

From October 28th to November 10th, the catheter was not required.

On November 3d, and the following day, she had intense thirst, and the catamenia appeared on the 3d, and lasted till the 7th. In the night of November 6th, she sweated a great deal; and on the afternoon of November 7th, she had nausea, her temperature went up to 102.6°, and she felt considerable pain in the left iliac fossa. These symptoms continued during the night and the next day.

On November 9th, there were the same symptoms, except that the pain in the abdomen was a little more diffused, and there was now tympanites. She also complained greatly of a parching thirst; she had had rigors during the morning and the preceding evening, was very lachrymose in manner, and had an unaccountable and alarming apprehension that she would soon die. For the first time, too, there was on this day a slight purulent discharge from the vagina. Hot fomentations, with opium and turpentine, were continuously applied to the abdomen; opium, in half-grain doses, was given every four hours; and milk-diet and ice to suck were ordered. The enemata had been discontinued.

On November 10th, the catheter had again to be used. The temperature was 99.8°, the pulse 96, and respirations 25. She had had a bad night, owing to frequent retching. There were distension and slight general tenderness of the abdomen, the girth of which was twenty-seven inches.

On November 11th, the patient complained of spasms and tenderness in the abdomen. The tongue was red, dry, and beefy, with prominent papillæ. The temperature was 101.6°, and the pulse 120; the respirations were 28 and shallow. The catheter was not required.

On November 12th, she lay with her knees drawn up, complaining of pain in the abdomen, the girth of which was now twenty-nine inches. There was much tympanites, but no marked tenderness on pressure. The tongue was in the same state as on the previous day. She experienced parching thirst, and vomited occasionally. The pulse was 126, not hard, but thready, and very compressible. There was marked muscular tremor, especially of the hands. She was very restless, talkative, and excitable. Towards the latter part of the afternoon, she was troubled with loud hiccough and retching. The temperature was 99.2° in the morning; 99.6° in the evening During the night, she slept for intervals from 12 to 2 A. M.; she then awoke, complaining of increased pain and fulness in the abdomen. Fresh fomentations seemed to relieve this; but about 4 A. M. on the morning of the 13th, she died quietly within a few minutes. Her death was quite unexpected by the nurse, who had been closely watching by her side.

At the *post-mortem* examination, made ten hours after death, Dr. Fowler found recent general peritonitis gluing together the coils of intestine, and in the peritoneal cavity about one pint of turbid fluid, with floating flakes of lymph. The inflammation was most marked about the brim of the pelvis. Recent adhesions bound the structures in the broad ligament to the neighbouring parts on each side. It seemed probable that the peritonitis had commenced at the left ovary, in which were several small collections of pus, one of them communicating directly with a sloughy point, surrounded by a patch of purulent membrane, on the surface of the ovary. The liver and spleen were congested. The right ureter was somewhat distended, as were also the pelvis and calyces of this kidney. The inner surface of the pelvis showed signs of violent and recent inflammation. The surface of the kidney was mottled; and, on section, the cortex appeared diminished. The left ureter and pelvis were more dilated than the right, and contained purulent-looking urine; and in the left kidney the inflammation was more extreme, and had extended along the uriniferous tubules. The bladder was pushed up and towards the right iliac fossa; and, though quite empty, reached one inch above the upper border of the os pubis. Its walls were hypertrophied, and sacculated, and beneath the mucous membrane there were small extravasations, but no appearance of cystitis. The vagina was elongated; and, owing to the upward traction of the uterus, the vaginal part of the cervix uteri was obliterated, so that the os was a mere slit in the posterior vaginal wall. The uterus and its appendages were displaced upward and to the left by a large tumour, which almost filled the pelvis, and was growing in the right wall of the uterus. The cavity of the uterus was found to measure four and a half inches; its axis was oblique, being directed upwards and to the left. Both the Fallopian tubes contained pus. The right ovary was healthy; but the left, though of nearly normal size, was suppurating at various points. The tumour in the right wall of the uterus somewhat resembled the uterus in shape, but far exceeded it in size, and measured six inches in its long diameter and three inches transversely. The uterine tissue was plainly seen on the surface of the tumour, showing it to have been of intramural origin. On section, it had all the characters of uterine fibroids. At the upper part of the uterus, two small fibroid tumours, about as large as chestnuts, were seen sessile upon the peritoneal surface. The left pleura was normal; but there was recent lymph over the lower half of the right pleura, but no fluid in the pleural cavity.

Remarks.—The first step was to ascertain by vaginal and rectal examination the cause of the displacement of the bladder, and of the intermittent retention of

urine; and to connect it, if possible, with the fulness in the left iliac fossa. The next question was as to the character and connections of the tumour, and whether it could be removed, or in any other way dealt with, so as to allow the bladder to resume its place and functions. This was a question of real difficulty in the case. As a rule, I believe it may be assumed that, in the female, a pelvic tumour which pushes the bladder out of the pelvis and to one side of the median line, which causes lateral and upward displacement of the uterus, and is felt *per rectum* as a large mass on the front aspect of the bowel, is, in all probability, either an enlargement of the uterus itself, or of one of the appendages of the uterus I have seen, however, in one instance, the bladder pushed right out of the pelvis into the abdomen, by a hydatid cyst. In E. B.'s case it was possible to exclude certain other not uncommon forms of pelvic tumours. Thus (1) pelvi-peritonitis (which M. Nonat, as well as Bernutz and Goupil, tell us, have not unfrequently been mistaken for fibroid of the uterus), and (2) pelvic cellulitis were negatived by the absence of any coexisting or previously existing affection of the generative organs, by the absence of all pregnancies or confinements, and by taking into consideration the sudden commencement of her illness, marked by the single symptom, retention of urine. (3) Hæmatocele was excluded by the freedom from all previous catamenial disturbance, of sanguineous discharge, and of febrile symptoms; and by the altered condition of the os and cervix uteri, the increased dimensions of the uterine cavity, and the mode of onset of the illness. (4) Certain morbid states of the uterus itself could be excluded, such as flexion of the womb; because, though these may either cause retention of urine or difficult defecation, the tumour in this case was large enough to flatten the rectum and displace both uterus and bladder, and the uterine sound could be passed, and turned easily in the uterus. (5) Cancer of the body of the uterus sometimes occurs without the os or cervix being affected, at any rate for a long while; in cancer, too, the uterine cavity may be markedly increased, and the uterus itself is commonly fixed, and presses considerably upon the rectum. But cancer was negatived by the entire absence of uterine hemorrhage and of vaginal discharge, by the comparatively unimpaired state of her general health, and by the great displacement of the bladder to one side, and of the uterus to the other—a condition which, so far as my experience goes, is not met with in cancer of the fundus uteri.

Thus the diagnosis was brought down to a question between fibroid of the uterus and ovarian tumour. The reasons for thinking it a fibroid, rather than an ovarian tumour, were the firm hard texture, the absence of any elasticity or fluctuation, the displacement of the uterus in the direction of the tumour, the altered condition of the os and cervix uteri, the enlargement of the cavity of the womb, and the slight degree to which the tumour had risen out of the pelvis. The retention of urine, too, was more in favour of fibroid than of ovarian tumour; for, though ovarian tumours, when retained in the pelvis, have in some instances given rise to retention of urine, dysuria, and other bladder-symptoms, yet there is a great and frequent tendency for fibroids to irritate and mechanically obstruct the bladder. It is even said (West, *Diseases of Women*, p. 289) that retention of urine is occasionally the first symptom of uterine fibroid; and the accuracy of this statement is verified by this case. On the other hand, the elongation of the cavity of the uterus is not at all inconsistent with ovarian tumour, and is commonly stated to be not very unfrequently associated with it.

The reasons for thinking the tumour ovarian, rather than fibroid, were, first and chiefly, the absence of hemorrhage. Hemorrhage being one of the most characteristic signs of fibroid, its absence is of itself sufficient to lead one to suspect the ovary, rather than the uterus, as the seat of the tumour; but this case shows that

the most complete immunity from hemorrhage ought not to influence us too strongly against the possibility of fibroid. Secondly, the one-sided situation of the tumour, the high position of the uterus, the smooth and even surface of the tumour as felt *per rectum*, the apparent solitariness of the tumour (fibroids being generally multiple), and perhaps, also, the age of the patient, were also in favour of ovarian tumour.

Nothing could be inferred from the rate of growth of the tumour, since nothing wrong was suspected until the first attack of retention, five months before admission. One means towards a more positive diagnosis was purposely withheld, until after the approaching catamenial period had passed; and very fortunately, as the case terminated, this was so. I refer to puncturing with the aspirator. This, by yielding a negative result, would have been another factor in favour of fibroid, and would doubtless have clinched the diagnosis.

After thus establishing the non-cystic nature of the tumour, no treatment could have offered any prospect of permanent or real relief. Ergot, which has been found useful in some cases, would have been tried, but one cannot think with much if any good result. Even if an exploratory abdominal section had been ventured upon, the operation must have been abandoned, owing to the firm connections of the tumour, and the way in which it was wedged into the pelvis. The patient, therefore, would have been doomed to a life of misery, had not an acute intercurrent disease mercifully carried her off.

The attack of peritonitis was, at the outset, quite local, beginning in the left iliac fossa, *i. e.*, the situation of the fulness felt at the time of her admission. From this it spread over the whole abdomen. As the attack followed immediately upon a catamenial period—indeed, commenced before the period was quite over—it was supposed to have been excited by inflammation of the left ovary; and on the hypothesis that the tumour was ovarian, it was thought that the whole, or a part of the cyst had suppurated (Case by M. Nonat: Bernutz and Goupil, vol. ii. p. 145)—suppuration being indicated by the variable temperature and repeated rigors. Still, on the other hypothesis, it had to be borne in mind that fibroids of the uterus may set up fatal purulent peritonitis without the ovaries, Fallopian tubes, or vagina being affected. (Case by Bernutz and Goupil in *Diseases of Women*, vol. ii. p. 156.)

The immediate cause of the peritonitis was doubtless the extension of inflammation from the ovary, or along the Fallopian tubes to their fimbriated ends; whilst the cause of the abscess in the ovary (itself a rare condition), and of the suppuration in the Fallopian tubes, as well as of the dilatation of the ureters and the acute inflammation of the kidneys is to be looked for, I think, in the irritation, displacement, and compression exercised upon these various structures by the uterine tumour.—*British Medical Journal*, May 21, 1881.

MONTHLY ABSTRACT.

Anatomy and Physiology.

On the Sense of Light and the Sense of Colour.

Dr. CHARPENTIER details some interesting physiological experiments (*Archives d'Ophthalmologie*, Dec. 1880) on the perception of light as distinct from that of colour. In these researches he used an instrument devised by himself (figured in Wecker's and Landolt's *Ophthalmologie*, tome 1, p. 530), which enabled him to measure exactly the amount of light required to excite respectively luminous or chromatic sensibility in various portions of the retina. He found that all coloured light, however simple in composition, if gradually augmented above zero, first of all produces a sensation of mere luminosity, and only subsequently one of colour. The chromatic sensation is at first ill-defined, and does not become distinct and definite until the light has assumed a certain intensity, which varies with its nature and the portion of retina affected. The luminous sensation is separated from the chromatic by a larger interval, in proportion as the region of the retina affected is distant from the yellow spot. The sensation of white is due to the neutralization of two or more chromatic sensations, owing to which neutralization the sensation of luminosity, which is generally masked, reappears and predominates. A certain quantity of light is lost in overcoming the inertia of the ocular apparatus. This is shown by the fact that, after a sojourn in darkness, a certain minimum intensity of light is required for perception, but this minimum becomes considerably reduced after the retina has been stimulated by previous excitation. On the other hand, the amount of light required to stimulate the chromatic sense remains the same in each case. Chromatic perception is not increased or diminished by the addition of white light; for although in any given case certain coloured rays have been necessarily added, these rays are neutralized by the complementary colour rays existing in white light.—*Lond. Med. Record*, April 15, 1881.

Materia Medica and Therapeutics.

On Blisters.

In a communication to the Société de Thérapeutique, published in the *Revue de Thérapeutique*, p. 152, M. CORNIL states that, when cantharides is administered to an animal—for instance, to a rabbit—either by the mouth or by absorption through the skin, as when a blister is applied, poisoning is produced, characterized by cystitis, nephritis, and inflammatory lesions in the liver and in the lung. In fact, twenty minutes after the cantharides is injected, the following lesions are found in the cavity of a glomerule of the kidney. A large number of white globules are found between the envelope of Miller's capsule and the vascular bundle which composes the Malpighian glomerulus. In addition a granular exudation is found in the uriniferous tubes, which fills and obliterates their calibre. At the end of an hour, the lesions are characterized by the proliferation of the cells, which by mutual pressure become irregularly flattened. There exists, therefore, a true catarrh of the uriniferous tubes. In the bladder the disturbances

are nearly of the same kind, but the lesions are superficial; the irritating principle of the cantharides has acted directly on the internal surface of the bladder. In the lung, the small bronchial tubes are filled with white pus-corpuscles; these lesions, which indicate inflammation of the mucous membrane, are found in all the parenchyma, and are the consequences of the irritating principle, the cantharidine, carried into all the organs by the circulation. The same kind of lesion of its mucous membrane is found in the larynx and in the trachea. If a blister be left on sufficiently long, the same lesions are obtained. M. Cornil therefore thinks that large blisters applied to the chest, and left on from fifteen to twenty hours, are more injurious than useful. By this method, not only are cystitis and nephritis brought on, but inflammation of the bronchi and of the pulmonary parenchyma itself. He has therefore arrived at the conclusion that, in order that blisters should not be injurious, they should not be allowed to remain on more than from three to four hours.—*British Med. Journal*, April 30, 1881.

The Action of Tannin on the Animal Body.

Among the oldest known and most frequently employed medicines are to be reckoned the astringents; but pharmacological investigations have been very seldom directed towards them. In a recent paper (Virchow's *Archiv*, Band lxxxi. p. 74), Lewin furnishes a very exhaustive account of one of the most important of these, namely, tannin. The officinal preparation of this drug being by no means pure, its separation for the observations detailed in this paper was conducted by means of Löwe's method, which is based upon the property of concentrated solution of common salt to precipitate only tannic acid, and not gallic acid; the pure tannic acid being subsequently separated from the chloride of sodium by means of acetic ether. Gallic acid has the property of precipitating albumen and albuminous substances from their solutions. These precipitates, insoluble in water, dissolve in an excess of albumen or of gelatine solution, in dilute lactic acid, in carbonic acid, and in caustic alkalies. Tannin loses its property of coagulating albuminous bodies, when it is mixed with alkali, to the point of weak alkaline reaction. The alkaline tannate, so produced, has no longer an action upon albumen, but still possesses the characteristic astringent taste of unaltered tannin. The artificial digestion of albumen is not interfered with by the presence of tannin, which substance neither acts upon the peptone during its formation, or subsequently to that stage of digestion, nor does it precipitate pepsin. This behaviour is to be ascribed to the presence of free hydrochloric acid.

When a few drops of solution of tannin are added to blood, there forms, at the point of contact of the two fluids, a precipitate of tannin-albuminate, which disappears when the fluids are shaken up. If more of the tannin be added, a point is at length reached when the precipitate is no longer redissolved. This point corresponds to the disappearance of the alkaline, and the commencement of the acid reaction. Not only the albumen, but also the colouring matter of the blood, becomes altered on the addition of tannin; the blood showing, when examined with the spectroscope, the absorption-bands of acid hæmatin.

The antiputrefactive action of tannin was long questioned, since the substance itself in solution, after long keeping, decomposes. But it seems clear that such an action does exist. When a solution is added to putrid blood, the disagreeable odour disappears after a few minutes, and the mixture may be kept in an open vessel, exposed to the air for weeks, without undergoing farther decomposition. This action seems to depend upon the strong chemical affinity of tannin for albuminous substances, whereby the organisms of putrefaction are themselves seized upon, and their development hindered.

The outward application of tannin to the various tissues alters their physical characters. The connective tissue shrinks together and hardens. The muscles are so affected that their primary and secondary stretching are absolutely less than that of normal muscle; while, when the weight is removed, they return more exactly to their original length. This action upon the muscles takes place in the frog, whether the tannin be injected into the peritoneal cavity, or into the lymph-sac. The cause of this distant astringent action, after the subcutaneous injection of tannin, depends upon two factors: firstly, upon the energetic hygroscopic character of tannin, the abstraction of the water from the tissues rendering their cohesion and elasticity greater; and, secondly, and still more importantly, upon the power of tannin to take up oxygen. The alkaline tannate abstracts oxygen from the tissues, and thereby gives rise to the phenomena pertaining to deficient oxygeneration, which, in the muscles of the frog, correspond exactly with the conditions to which the subcutaneous injection of tannin gives rise.

The absorption of tannin into the body takes place in the following manner: When the solution enters the stomach, it does not affect the peptones present, since they are in a solution of hydrochloric acid; but the fluid unaltered albuminous bodies are changed into a tannate of albumen, provided that there is no excess of dissolved albumen, or of lactic acid. The albuminate of tannin, if it be formed, becomes digested, and the tannin passes into the vessels. As it enters in small quantities, it dissolves in the alkaline blood or lymph, and circulates as a soluble alkaline tannate.

The following are some of the practical suggestions in regard to the administration of tannin, which may be derived from the observations contained in this very able paper: It is to be borne in mind that, when tannin enters the stomach, it forms with albumen precipitates, which, although soluble, require for their solution the presence of certain definite conditions (for example, excess of albumen, of lactic or of hydrochloric acid). If the albuminate of tannin be not soon dissolved, or if the tannin be given in the form of a powder, the solid particles adhere to the gastric walls, and produce extensive irritation of the mucous membrane. This occasions the most uncomfortable sensations, feeling of weight and heat in the epigastrium, loss of appetite, etc. In order to avoid this, the tannin should be given, either as a solution of albuminate of tannin, or as alkaline tannate. In any case, it should not be administered in the form of a powder. A solution of albuminate of tannin can be readily prepared in any concentration, if a solution of albumen be added to tannin dissolved in a little water, and the resulting precipitate redissolved by excess of albumen. Absorption is still more readily accomplished when the drug is given in the form of an alkaline solution, by the addition of sufficient carbonate of soda to render the reaction alkaline. Or, finally, a third rational method of administration consists in precipitating the solution of tannin by means of albumen, and adding sufficient carbonate of soda to dissolve the precipitate.—*London Med. Record*, May 15, 1881.

Medicine.

Tuberculosis and Scrofula.

In a recent communication to the Société Médicale des Hôpitaux de Paris, M. GRANCHER discussed this well worn, but ever interesting subject by the light of recent researches. He considers as primordial the vitreous degeneration, which Virchow attributes to reciprocal pressure of the cells, and Cornil to the primary obliteration of bloodvessels, but which he believes to be produced by a "dys-

trophy," attacking even the embryonal elements. The caseous nucleus, the giant-cell of tubercle, the lesion of caseous pneumonia, are formed on the same type as the granular. An inflammatory process, accompanied by exudation of fibrin, is developed round the already existing tubercular giant-cell. The microscopic or Köster's tubercle, or the elementary tubercle of Malassez, and the follicular tubercle of Charcot, are essentially characterized by having a giant-cell in the centre, upon which is a vitreous layer of epithelioid cells, and a second layer of embryonal cells. In this anatomico-pathological prototype are two elements, one fibrous and capable of hardening, the other capable of caseation. The characteristic of tuberculosis is a fibro-caseous neoplasm, of a nodular form, tending to become caseous rather than to become hard.

M. Grancher disputed the strange opinion that scrofula is nothing but a local tuberculosis, because the elementary tubercle of Köster is found there; but this never exists there except in an embryonic state; in tuberculosis only, it develops till it arrives at the adult stage, or that of the granulation type. If the giant-cell were sufficient to characterize tubercle, as Schüppel says, then not only scrofula, but even syphilis, and certain sarcomata, would be classed together. Between scrofula and tuberculosis there is only a slight relationship.

In the discussion which followed, M. Féréol remarked that M. Grancher would be more logical in defending the doctrine of the fusion of the two diatheses, as suggested by Friedländer in 1871, and adopted by Charcot in 1877. M. Brissaud, he said, frequently found even the granulation type in strumous deposits. Since scrofulous deposits engender miliary tubercles, why not admit that scrofula engenders tuberculosis? Certainly clinical experience was not opposed to that being the case. Tuberculosis would then be, only, a particular type of scrofula. M. Labbé insisted on the fact that frequently simple inflammations terminate in tubercle, apart from any apparent diathesis, especially after mental emotion, excess, and dyspepsia. M. Cornil has, far from being an unicist, considered that diseases differing in cause and their symptoms can give rise, at a certain period of their evolution, to similar anatomical productions. Tuberculosis is characterized by a constant neoplasm—tuberculosis granulation—of variable aspect according to its period of development, and by the general appearance of the lesions, their seat, and their evolution. Scrofula embraces, on the other hand, a series of very different morbid conditions, to which are added acute or chronic inflammations, of which the oldest tend to caseation, a termination which is also seen in syphilis, in sarcoma, and in chronic pleurisy. M. Grancher had insisted on the pathological anatomy of lupus being similar to that regarded by most as scrofula, in which, however, one finds again the primitive tubercle or tuberculous follicle, never the typical tuberculous granulation; but this last is not found in tuberculosis of the mucous surfaces. The symptoms, course, and evolution suffice to separate lupus from tuberculosis. A single morbid element cannot characterize a disease. Thus, the organism found in diphtheria resembles those of quite different affections; the false membranes of inflamed mucous patches, from which syphilis may be inoculated, are histologically similar to those of croup. M. Damaschino admitted the two diatheses. Scrofula is, as it were, a soil favourable for the growth of tuberculosis equally with other conditions of debility. M. Thaon was an unicist; he admitted the identity of scrofulous and tuberculous glands. Pulmonary tuberculosis, he said, is only scrofula of the lungs; but there is, as it were, an antagonism between the cutaneous or glandular manifestations of scrofula and the manifestations in the lungs. Scrofula, a diathesis of feebleness, attacks the points of least resistance. It is uncommon in the lungs of the mountaineer, fortified by, as M. Thaon said, "gymnastique respiratoire." Tubercle is a special not a specific inflammation, in miliary or voluminous foci, tending to caseation or to

fibrous degeneration, and the evolution of which is accompanied by fever. Nothing analogous to this is to be found in tumours, such as sarcoma or carcinoma. M. Labbé pointed out that Laennec regarded tuberculosis as a result of scrofula, the tendency of all debilitating causes, a malady acquired, and not diathetic. Scrofula, a constitutional vice, like all physiological debility, engenders, or at least predisposes to, tuberculosis. Pulmonary inflammation, narrowing of the pulmonary artery, aneurism of the thoracic aorta, and deformity arising from rickets, lung-disease produced by dust, etc., act in the same way. Tuberculosis is not a specific malady; the existence of tubercle gives it, however, a special character. Heredity of tuberculosis is not so undeniable as that of gout. M. Ferrand did not consider tuberculosis as a diathesis; equally with scrofula and with gout, it is a lesion appearing late in certain diatheses, but not special to any one of them. He did not deny, nevertheless, that it may be developed independently of any diathetic or constitutional disease. A scrofulous or a gouty person may become affected with tubercle, but a tuberculous person does not become scrofulous or gouty. Phthisis of scrofulous origin specially affects the mucous surfaces, and undergoes caseation. Consumption, in gouty persons, attacks the serous membranes, and develops into fibrous tissue. Pathological anatomy is not, at present, able to trace any natural affinity between tubercle and syphilis or glanders, any more than between these two last-named diseases. M. Rendu said that he was dualistic in his views, because, in his opinion, the scrofulous tumour does not exist, because the tuberculous follicle does not characterize tuberculosis, and because the giant-cell is not peculiar to tuberculosis. There is nothing characteristic in scrofula, unless it be "torpidity;" it is quite the contrary, however, in tuberculosis, to such an extent as to call to mind an infective, or even a parasitic, disease. This is more especially the case when one considers that it presents, as it were, foci of contagion of epidemic concentration; that its inoculation seems possible; and that it is frequently acquired. Regarding the points of resemblance between scrofula and tubercle, it can only be said that scrofula makes the body a favourable soil for the development of tubercular germs.—*British Med. Journal*, April 23, 1881.

Treatment of Typhoid Fever.

Dr. HALLOPEAU (*L'Union Médical*, March 21) has been making a study of the treatment of typhoid fever by calomel, salicylate of soda, and sulphate of quinine. He has communicated his results to the Société Médicale des Hôpitaux, and his conclusions are as follows: 1. Salicylate of soda and sulphate of quinine generally exercise an appreciable action over the temperature of typhoid fever patients. 2. The action of salicylate of soda is not habitually continuous; at the end of two or three days, even when fresh doses are administered, new rises of the thermometrical curve are observed. As a rule, however, they only attain the initial figures in a temporary manner, and the centre of the thermic oscillations generally remains depressed. 3. Two grammes (31 grains) of salicylate of soda are, as a rule, sufficient to produce an antipyretic action. 4. In doses of 4 grammes and upwards, this drug seems capable of itself producing symptoms, and especially of increasing the dyspnœa, augmenting pulmonary congestion, favouring the tendency to hemorrhage, and sometimes inducing delirium and restlessness. 5. These accidents may be avoided if the salicylate of soda be given in doses of two grammes only, if it be not prescribed for more than three days successively, and if contra-indications be duly observed. 6. These contra-indications are especially thoracic complications, serious cerebral symptoms, and hemorrhage. 7. By prescribing sulphate of quinine and salicylate of soda alternately,

the centre of the thermic oscillations is most frequently maintained at a comparatively low figure. The pernicious effects of excessive temperature are thus avoided, and it would seem at the same time that a favourable action is exerted over the course of the disease. In this way, an equally powerful control is obtained over the temperature as with cold baths, without exposing the patients to the same accidents. 8. The antipyretic action of sulphate of quinine is produced even when that of salicylate of soda seems to be exhausted, and *vice versâ*. The therapeutic effect of one is added to that of the other, but not their toxic effects. 9. Cold lotions, cold applications to the abdomen, and cold enemata, may be advantageously employed as accessories at the same time as the antipyretics. 10. In cases when hyperpyrexia persists, notwithstanding this treatment, the daily doses of sulphate of quinine may be increased to one and a half, two, or even three grammes. Four grammes of salicylate of soda may in like manner be given, provided that the dose be repeated not oftener than every second or third day, and that it be ascertained that the medicine is being eliminated by the urine.—*London Med. Record*, April 15, 1881.

—

Gangrene of the Vulva in Typhoid.

Prof. SPILLMANN, of Nancy, terminates an article in the *Archives Générales* of March with the following conclusions: 1. Gangrene of the female genital organs, although rare, nevertheless constitutes one of the most serious complications of typhoid fever. 2. It may be manifested at first in the form of simple œdema, of an inflammation of the vulvo-vaginal glands, or of small superficial eschars confined to the labia. 3. In bad cases the gangrene appears in the humid form, extends over the entire vulva, and may even invade the vagina, the thighs, and the trunk. It often, under these conditions, terminates with symptoms of gangrenous infection. 4. The gangrene may also be confined to the vagina, and then often remains unperceived, and may, at a later period, give rise to stricture of the vagina, with retention of the menstrual discharge. 5. Vulvar gangrene is sometimes induced by a true local infection, and is then propagated by means of erosions or ulcerations of the vulva, or of excretory ducts of the vulvo-vaginal glands. 6. Syphilitic lesions of the vulva seem to easily undergo transformation into gangrenous centres when the patient is attacked by typhoid fever. 7. Gangrene of the vulva is always a serious complication, and in bad cases it proves fatal in two cases out of three. 8. The possibility of such complication should always be borne in mind; and hygienic precautions should always be put in force for all women who become the subjects of typhoid fever. In the adynamic forms of the disease a minute examination (*toilette minutieuse*) should be made daily. 9. Local antiseptic treatment should be put into force from the commencement of the complication. 10. The cicatrization of the wounds should be attentively watched.—*Med. Times and Gazette*, April 23, 1881.

Sprue.

There are a multitude of diseases peculiar to tropical and subtropical countries to which the inhabitants are liable, and which foreigners may acquire when exposed to the corresponding morbid causes. There is another class of diseases peculiar to those countries, attacking foreigners, and but seldom, if ever, affecting the natives. One of the latter, known in India and well known in Java, where it goes by the name of sprue, has hitherto received little specific notice from medical writers, though, from its extreme fatality, it deserves careful study and attention. Sprue is defined by Dr. PATRICK MANSON, of Amoy, who has devoted much attention to it, as an extremely chronic and insidious disease peculiar

to warm climates, the principal symptoms of which are referable (1) to a remitting inflammation of the mucous membrane of the mouth and alimentary canal generally; (2) to diarrhœa and irregular action of the bowels; (3) to anæmia and general atrophy. Great wasting accompanies it, altogether out of proportion to the amount of diarrhœa. The victims have all a withered shrunken appearance. When the disease is of some standing, the patient is feeble, irritable, incapable of much mental effort, and anæmic. It is exceedingly insidious in its onset, and very slow in its progress. Dr. Manson has watched a case for several years. This chronicity is exceedingly characteristic; the patient can seldom say exactly when his disease began, nor, if interrogated from time to time, during its progress, can he say positively he is better or worse. It is only when comparison is made between the condition and weight of the patient at dates widely apart that the gradual and sure progress of the disease can be appreciated. The prognosis in a well-marked case must be grave indeed, unless the sufferer be speedily removed to a colder and more temperate climate. According to Dr. Manson's experience, so long as the patient remains under the conditions in which his disease was acquired, medicine and dietary, although they may do much to mitigate suffering, will not effect a cure; and, after one, two, or three years of suffering, there can be only one termination. As to the cause of sprue, Dr. Manson can only ascribe it to the general unsuitability of the European constitution to tropical climates. It is just possible that some accident to the alimentary canal may act as the immediate and exciting cause, and determine the advent of sprue in those constitutionally prepared by the warm climate and other predisposing influences. Nothing seems to have so powerful an influence in aggravating the disease, and therefore, probably, in inducing it, as long-continued high temperature. In his attempts at cure, Dr. Manson has tried many drugs; but they have one and all disappointed him; and he has come to the conclusion that there is only one remedy for sprue (viz., leaving the country); and that, to be effective, should be tried early in the disease. Is not "sprue," after all, a form of "idiopathic" or "progressive pernicious" anæmia, as described by Dr. Coupland in his lectures now in course of publication in this Journal?—*British Med. Journal*, April 2, 1881.

—

Leukæmia.

Professor W. LEUBE and Dr. R. FLEISCHER (Virchow's *Archiv*, Band lxxxiii. Heft 1) publish the case of a strong and healthy woman who developed in four months, after a normal confinement, all the symptoms of rapidly advancing anæmia: diminution of strength and nutrition, vertigo, headache, loss of appetite; at the same time pain and swelling occurred in the left lower extremity, which disappeared only after some time. Five weeks later, examination showed only extreme anæmia, with blowing murmurs over the heart, and a small, easily compressible pulse; no obvious enlargement of liver, spleen, or lymphatic glands. The number of the red corpuscles was notably diminished; that of the white corpuscles was absolutely and relatively greatly increased. The left tibia and tarsus were painful on pressure. The left leg was amputated above the knee for rapidly spreading gangrene. The patient died six days later. The necropsy showed intense anæmia of all the internal organs; advanced degeneration of the heart's muscle; no changes of the liver, spleen, or lymphatic glands; a chronic gastric ulcer. Red hyperplastic marrow was found in the bones, with numerous nucleated red blood-corpuscles (transition forms) and numerous marrow-cells. This lymphoid red process in the marrow has been found by Neumann and others in various cachectic conditions, and is regarded as being the consequence of the anæmia. They conclude that either this process must occasionally and

exceptionally give rise to a great development of white corpuscles as in this case, or it must be admitted that the source of the leukæmia cannot always be discovered in the usually recognized blood-forming organs, but that the disease must be regarded as an independent blood disorder.—*London Med. Record*, April 15, 1881.

—

Epidemic of Sweating Sickness.

M. JULES ROCHARD has reported (*Le Prog. Méd.*, No. 10) to the Academy of Medicine on the epidemic which occurred in the island of Oléron during the summer of 1880. The disease began in June in the village of Allards, and remained there till the 2d July, during which time there were five deaths. In July a death occurred in a neighbouring village, and became the cause of a new epidemic. The disorder was the sweating sickness, characterized by its sudden onset, special eruption, and grave symptoms. The cases became so numerous that the two doctors on the island were unable to fulfil the requirements of the situation, and two naval surgeons were sent to assist. The disease spread all over the island. No medical man was attacked. The contagion seemed to emanate from the corpses; putrefaction set in very early. The coffins were made very badly, and the products of decomposition probably escaped and contaminated the clothes of those who carried the coffins to the cemeteries; hence the frequency of the disease among these. According to Magnel, the temperature is 41 deg., 42 deg., and 43 deg. Cent. (105.8 deg., 107.6 deg., and 109.4 deg. Fahr.), but in this epidemic such high figures were not noticed. At the commencement it reached 39 deg. Cent. (102.2 deg. Fahr.), and remained at about 37 deg. and 38 deg. Cent. (98.6 deg. and 100.4 deg. Fahr.), while in cases where the sweating was suppressed it reached 41 deg. and 42 deg. Cent. The treatment consisted of ipecacuanha in doses of 1½ grammes (22 grains). Refrigeration gave good results in some cases of high temperature.—*London Med. Record*, April 15, 1881.

—

Antiseptic Treatment of Diphtheria.

Dr. WEISE (*Berlin. Klin. Wochenschrift*, 1881, No. 4) advocates the adoption of the following measures in the treatment of diphtheria. He prescribes a solution of salicylic acid, consisting of one part of salicylic acid and twenty-five parts each of rectified spirit and glycerine. This, although a strong solution, is quite free from danger. The spirit, he explains, is used because, in former cases, benefit was derived from the local application of brandy to the throat; and the glycerine is added to obtain a less irritating solution. If the patient can gargle, the author employs a 1 in 300 salicylic acid gargle. Should the attack be very severe, he prefers a solution of benzoate of soda, 1 in 40, or even stronger. Coincidently with this treatment, he gives Hungarian wines. He pays particular attention to maintaining the patient's strength, and orders nourishment to be taken constantly, in the form in which it can be most readily assimilated. He speaks highly of Rosenthal's extract of meat mixed with yolk of egg, but gives solid food if it can be borne. His directions are somewhat as follows: At one o'clock, paint or gargle the throat with the salicylic acid solution; at half-past one, give a teaspoonful of Hungarian wine; at two, the benzoate of soda; at half-past three, a teaspoonful of Hungarian wine; and, during the next half-hour, more gargling with salicylic acid; the treatment being continued night and day without intermission, except that at night the intervals may be an hour, instead of half an hour. If possible, he employs a special apparatus of his own—a combination of tongue depressor and spray. This, by reaching the back of the tongue, admits

thorough examination with the simultaneous application of an antiseptic. In few seconds, the whole throat can be washed out with the salicylic acid solution; nd this is very necessary in preventing the spread of the disease. Moreover, by is method, bleeding may be speedily arrested. Sometimes he employs a 5 er cent. solution of carbolic acid as a spray.—*British Med. Journal*, May 7, 881.

—

Transient Albuminuria.

Albuminuria without structural disease of the kidneys—a symptom of con-derable interest and of much practical importance—was the subject of a recent mmunication by Professor BAMBERGER to the *Vienna Gesellschaft der Aerzte*. Temporary albuminuria" it is often termed, but he suggests that "hæmatoge-c" would be a more accurate term as contrasted with "nephrogenic" due to ganic renal disease. This functional albuminuria is often trifling in amount, using merely opalescence of the urine under the ordinary reagents, but the nount of albumen is sometimes considerable. It may occur in individuals parently in perfect health, as Ultzmann and Leube showed, and their obser-tions have since been amply corroborated. It occurs also in febrile conditions, parently as a result of the blood state, although standing in no direct relation the pyrexia. Passive congestion and epileptic attacks also cause it. It is und in the convulsions from strychnine poisoning, but never in the abundant ntery urine of hysterical states.

What is the origin of this albuminuria? An answer can be best given to this estion by asking another. Why is not albumen always present in the urine, ce all capillary vessels allow albumen to pass through their walls, and it would remarkable if those of the kidney were any exception to the rule. Wittich t forward the theory that the urine which passes through the capillaries of e Malpighian bodies is always albuminous, but that its albumen only serves to urish the epithelial cells of the urinary tubules, and that the albumen which is t thus used passes back into the circulation. This theory presents the difficulty t it assumes that the epithelium of the kidney is nourished in a different way m all other epithelium, but it has the support of the pathological fact that en the epithelium is removed from the kidney, albuminuria occurs. And yet, the other hand, intense fatty degeneration of these cells may exist, as, for tance, in phosphorus poisoning, and no albumen may appear in the urine; ile in cases of transient albuminuria, in which, for instance, albumen appears the urine after an epileptic fit, it is not conceivable that this explanation will fice. Rosen has brought forward an experimental objection to Wittich's ory. He placed small fragments of fresh kidney in boiling water, and thus ed the albumen in the position in which it was produced. In diseased kidneys found coagulated albumen in the urinary tubules, but he never found it there healthy organs.

Physiologists assert that albumen is retained in the kidneys on account of the ssure-conditions of the circulation; the pressure is sufficient to lead to the nsudation of water and saline substances, but not of albumen. It may be ed, however, How does the pressure here differ from that in other capillary sels? The size of the renal arteries in proportion to the organ, the structure l arrangement of the capillaries, all point to a high blood-pressure in the kid-ys, a condition in which substances only slightly filtrable should readily pass ough, albumen among them. Heidenhain goes further, and asserts that thing of the nature of filtration occurs in the kidney, basing his assertion on relation which the amount of urea bears to the quantity of urine.

Another explanation which has been given is that the epithelial covering of the smallest renal capillaries keeps back the albumen. Mucous membranes only allow the escape of an albuminous fluid when they are denuded of their epithelium. This theory, however, holds good only for the living kidney; albumen passes out of the kidney after death in spite of the epithelium. Moreover, the epithelium is not equally retentive of all varieties of albumen; egg-albumen, for instance, injected into the vessels rapidly passes out in the urine; serum-albumen does not, while the albumen of red blood-corpuscles, the hæmoglobin, rapidly passes out in the urine if the corpuscles are destroyed.

Runberg has asserted that the amount of albumen which passes through animal membranes varies inversely as the pressure; the lower the pressure the greater the amount of albumen. Hence he believes that when albuminuria is not dependent on structural alterations in the kidneys, it is to be ascribed to the diminution of pressure in the Malpighian glomeruli. He thus accounts for the albuminuria of mechanical congestion of the kidney, in which the blood-pressure in the aortic system is commonly much lowered. The diminished quantity of urine in this condition supports this theory, and also the beneficial influence of digitalis as a remedy for the condition. Febrile albuminuria he ascribes to the same mechanism, the lowered blood-pressure from the enfeebled state of the heart. He has not, however, sufficiently distinguished the influence of the two important factors in the circulation, the pressure and the rapidity of the movement of the blood. In order to ascertain afresh the influence of the first of these factors, Bamberger has performed the experiment of stretching two similar membranes (amnion or pericardium) over cylinders, and allowing equal quantities of albuminous fluid to filter through them, with and without the pressure of a layer of oil poured upon the top. In the first experiment he took some pleuritic fluid, which contained 1·174 albumen. He found that in the cylinder in which the pressure was the greater, the absolute quantity filtered and the absolute amount of albumen were greater, but that in both instances the percentage of albumen in the total filtrate was the same. A second experiment with ascitic fluid containing a large amount of albumen gave similar results. Quite recently Gottschall and Hoppe-Seyler have performed similar experiments, and have obtained the same results. Runberg's theory thus also becomes untenable, and there are other experimental objections to it. When the renal arteries are tied the blood-pressure falls considerably, but the kidneys become congested, and blood and albumen at once appear in the urine. Moreover, in febrile states, the albumen often appears a few days after the commencement of the pyrexia, and while the pulse is still full and bounding. Neither an increase nor a diminution of the blood-pressure will alone account for the transudation of albumen. The only other condition to which it can be referred is the retardation of the blood-current. Albumen is slowly filtrable, and may only pass through when it remains for a comparatively long time in contact with the wall of the vessel. The same relation is seen in inflammation, in which first there is a retardation of the blood current, and then the exudation of an albuminous fluid. This, however, is probably not the only factor. The epithelial cells of the Malpighian glomeruli may lose their function without presenting any anatomical alterations—a hypothesis which can be neither established nor disproved. Another factor is the vaso-motor action, consisting in either paralysis of the vaso-constrictors or irritation of the vaso-dilators. By dilatation of the vessels a retardation of the blood current can readily be produced. In this way the origin of the febrile albuminuria can be readily understood, since vaso-motor disturbances are frequent in that condition, apart from any direct relation to the amount of pyrexia. If the whole nervous system, and therefore also the vaso-motor system of the kidneys, is

deranged by an epileptic attack, albuminuria may readily rise in the same way. The same explanation—the hypothesis of a slight vaso-motor disturbance—affords also the most ready explanation of the occasional albuminuria of apparently healthy individuals. At the same time, the possibility of chemical changes in the circulating albumen must not be forgotten. Under some conditions albumen is probably formed which behaves in the same manner as egg-albumen or paraglobulin, and, unlike serum-albumen, filters easy, and may thus appear in the urine. This fact, indeed, renders it doubtful whether the phenomena are to be explained at all by the mere physical conditions. We know nothing of the reason why the different kinds of albumen are excreted with various degrees of readiness, and whatever condition is the cause of this difference may also, when deranged, be the source of the temporary albuminuria which still constitutes so great an enigma.—*Lancet*, March 19, 1881.

Menière's Disease.

Dr. EDWARD MENIÈRE has just published a memoir on the disease described by his father in 1861. Menière's disease is constituted by three principal symptoms: 1. The noises or whistlings which precede the crisis; 2. The vertigo, accompanied by nausea and vomiting; 3. Deafness, as a rule incurable. The writer of the memoir details at length the treatment of this disease (*La France Méd.*, p. 239), in which he follows the method proposed by Professor Charcot. The patients take after their meals pills composed of 10 centigrammes of sulphate of quinine and 10 centigrammes of fluid extract of cinchona. He thus commences with 30 centigrammes of sulphate of quinine, and goes progressively up to 70 and 80 centigrammes, and even 1 gramme; then he enjoins absolute abstention from it during a fortnight, three weeks, or even a month, but recommences during the first period of a month, giving 40 centigrammes at first setting off. The effect of the quinine is to diminish and cause the vertigo to disappear, and, on the other hand, to modify the deafness. M. Menière does not pretend to formulate a curative treatment of a disease against which all the resources of therapeutics have hitherto been unavailing, but quinine has, at least, the advantage of calming the most troublesome symptoms.—*London Medical Record*, April 15, 1881.

—

Paralysis of Hands and Feet from Diseases of Nerves.

Dr. T. GRAINGER STEWART reports (*Edinburgh Med. Journal*, April, 1881) three interesting cases, closely resembling one another, the most important clinical features of which were the coexistence of symptoms referable to the sensory, the motor, and trophic functions of the nerves, the localization of the symptoms in the feet and hands, the intensity being greatest at the most distal points, and the affection corresponding to certain districts of the extremities, and not to the distribution-areas of particular nerves; the symptoms depending on a lesion of the nerves themselves, and in his opinion due to a healing of the axis cylinder. Similar cases have been described by Duménil, of Rouen (*Gazette Hebdomadaire*, 1864 and 1866), Bablon (*Ibid.*, Dec. 1864), Eichhorst (Virchow's *Archiv*, Bd. 69), Eisenlohr (*Centralblatt f. Nervenheilkunde*, 1879), Joffroy (*Archives de Physiologie*, vol. vi. p. 172), and Leyden (*Zeitschrift für Klin. Med.* 1880).

Dr. Stewart finds that "from the facts observed in the cases which I have recorded, taken along with those recorded by others, and with some which, looking back, I now regard as examples of this condition, I find data for drawing up

a clinical history of the disease, which seems to me quite distinctive. Its commencement is usually acute and attended by more or less fever. While all the functions of the nerves speedily become affected, it is in connection with the sensory functions that the first changes manifest themselves. Sometimes there is acute pain, but oftener a numbness or peculiar tingling sensation in the affected parts, closely resembling the feeling popularly known as sleeping of the limb—a feeling which is more like this from the circumstance that action of the muscles or pressure upon the skin induces the uneasy or painful sensation commonly known as pins and needles. Along with this there is a distinct diminution of sensibility. Touch is felt indistinctly; two points so far removed from one another as to be distinguished in the healthy conditions are no longer distinguished, and the patient may have the greatest difficulty in localizing the impression which he feels. Sensory impressions are conducted slowly, and at the same time contact is felt painful. These feelings may begin simultaneously in the fingers and in the toes, or may affect first the one and then the other. It seems to be usually in both hands and both feet simultaneously, but not necessarily in an equal degree.

To these sensory changes motor symptoms speedily become superadded. At first there is mere paresis, and affecting the most distal parts; but the paresis spreads up the limb from one group of muscles to another, and as it does so the intensity of the process deepens in the parts first affected. The organic reflexes are very rarely affected, although when the disease spreads upwards it is sometimes found that those connected with the bladder, and perhaps the bowel, are involved. The skin reflexes are modified in proportion to the diminution of sensibility in the parts, being sometimes entirely absent, sometimes absent on slight stimulation, but present even in an exaggerated degree when a strong stimulus is applied. The plantar reflex is often altered, while those higher in the body are natural. The tendon reflex, and especially the patellar tendon reflex, appears to be early and completely lost in these cases. Ankle clonus may be present after the patellar tendon reflex is lost. With regard to voluntary motion, it is found that in some of the muscles it is absolutely lost; in others it is diminished to a greater or less extent. Within a week of the commencement of the seizure it may be found that the patient has no power of flexing or extending the toes and fingers, but retains power of movement of the ankles or the wrist. A week or two later these movements also have become lost, and ere long perhaps the legs and arms in their whole extent are absolutely helpless. There is no special interference with the co-ordinating functions. With regard to the reaction of degeneration, I have not been able to satisfy myself in the cases which I have observed.

The vasomotor and trophic changes manifest themselves most distinctly in the muscles which undergo atrophy—much more rapidly than would be the case in simple motor paralysis. The colour and texture of the skin, also, sometimes change from the normal, patches of congestion or of blueness appearing here and there, and glossiness manifesting itself, especially in the fingers. The nutrition of the nails also becomes altered. In several of the cases I have seen a very distinct degree of œdema not referable to any other than a nervous cause. The intelligence is perfect, and sleep is satisfactory except in so far as it may be disturbed by pain. There is no alteration of the condition of the spine or cranium.

The process may take some weeks, or perhaps months, to arrive at its full development. After a time it appears usually to become arrested, but at first no improvement is manifested. Gradually, however, the patient begins to notice some improvement. His pains or uneasy feelings diminish, sensitiveness to impressions increases, and he begins to feel that his power over the muscles is

returning. It is in the upper part of the limb that improvement first sets in. It gradually passes downwards, until at length there is complete recovery. The process may occupy a period of from two to six or more months.

The recovery from such a condition as this seems to be most remarkable. It would appear to one examining the lesion as if it must necessarily permanently destroy the nerve; and yet we must assume that recovery does actually take place, and that in no inconsiderable proportion of the cases. But what is even more remarkable is, that the process may recur in the same individual and in the same parts time after time. I have met with at least one case in which this apparently occurred three successive times within a few years.

In some cases, probably, the disease extends to involve the cord, and perhaps to pass into myelitis.

The superaddition of any acute disease must be regarded as most formidable where this disease exists. But while recovery occurs in a considerable proportion of cases, it is not the invariable result. In some the process induces permanent atrophy of the nerves, with consequent paralysis. In others extension of the disease may take place, and vital nerves or vital nerve centres becoming affected, death must follow. Further observation will show the proportions in which these various results occur.

I have no doubt that it will occur to many of you that probably in this disease we find the means of explanation of cases which we have regarded vaguely as spinal congestion, slight myelitis, or such like; and I expect that it will prove that cases of this kind are not very uncommon. I, at least, on looking back, can recall some in which I think I should now find the explanation by reference to this process.

If it be true that in some instances fibres of all kinds in mixed nerves may be thus affected, it seems reasonable to believe that in individual mixed nerves either the motor fibres alone, or the sensory fibres alone, might be the seat of change. And if so, we should expect to find in the former a clinical history closely resembling Landry's acute ascending paralysis; in the latter, certain forms of neuralgia with loss of sensibility.

It remains for me to mark off the clinical history thus sketched from those proper to some other affections with which, at first sight, it might be confounded. It resembles at first sight and in some respects the Acute Ascending Paralysis to which I have just referred, which was first described in 1859 by Dr. Landry. In it there is paralysis commencing at the distal parts and spreading upwards, sometimes terminating in recovery, sometimes extending to vital centres and so proving fatal. In the cases which do prove fatal no lesion has been found. The disease which I am bringing before you to-night differs from it in that it affects the sensory as well as the motor functions, and exhibits well-marked pathological changes. But the processes may, on further examination, turn out to be related to one another in the way I have just suggested. It also very naturally suggests the form of disease which was described in 1853 by Duchenne under the name of General Spinal Paralysis, and which he afterwards spoke of as Anterior Spinal Paralysis, acute and subacute, in which the lesion was more accurately defined by Charcot and Joffroy, and which has been termed by Kussmaul and Erb, Polio-myelitis anterior, by Westphal, Acute Atrophic Spinal Paralysis of adults, and by Eulenberg, Acute and Subacute Spinal Paralysis of adults. In that disease the lesion is situated in the anterior horns of gray matter, and the clinical features are well defined. Commencing generally acutely with some degree of febrile disturbance, there is developed paresis of the limbs, which rapidly passes into paralysis with speedy wasting of the muscles. It spreads from the legs upwards. The same process may occur in the arms; it may, indeed, begin in the

two places simultaneously, gradually advancing in the trunk as the cord becomes more extensively affected. The process may extend to vital structures and prove fatal, or it may become arrested and complete recovery take place, but throughout the course of the disease there is no affection of the sensory functions. Peripheral Paralysis of the kind we are describing differs from it in that it affects the sensory as well as the motor and trophic functions, and that it is so distinctly ascending in the limb it involves, while pathologically the changes are essentially different; and thus, although one of the most careful and distinguished of living workers in neurology, Professor Leyden of Berlin, draws special attention to the resemblance between them, it is yet clear that they are to be readily distinguished from one another.

There should be little tendency to associate this disease with Acute Transverse Myelitis, a malady in which the whole of the strands of the cord are diseased at the same point, for in that disease it commences to manifest itself at once at all points below the seat of disease, and does not spread upwards, as in our malady; moreover, in myelitis there is a marked tendency to alterations of the organic reflexes, to sloughing of skin, alkalinity of urine, and vesical catarrh, none of which occur in the malady we are considering.

Certain forms of diphtheritic paralysis more or less closely resemble the disease under consideration; but they may be readily distinguished by the fact that there is no history of any throat affection, no tendency to paralysis of laryngeal or pharyngeal muscles, nor is the distribution of the malady at all like what is seen in post-diphtheritic cases. It is interesting to remember in this connection that in some cases of diphtheritic paralysis Charcot and Vulpian have found a distinct lesion of the nerves of the affected parts, and that this has been confirmed by others. It will be interesting to ascertain how close the resemblance between them may be.

One of the main points of interest in connection with this disease is the light which it appears fitted to throw upon some obscure questions in nervous pathology; among these I may mention Locomotor Ataxia. You are all aware how frequently that disease is heralded by passing nervous attacks of various kinds, sometimes paralytic, affecting one nerve or some particular branch of a nerve, and generally after a time disappearing, but sometimes persisting. Such paralyses may be best explained by assuming them to be due to this disease. But, again, girdle pains often appear as an early symptom, and may be also quite reasonably referred to such a malady, for the girdle pain is usually associated with hyperæsthesia, and while it sometimes entirely disappears, it sometimes also produces a permanent anæsthesia of the region affected. Another very distressing symptom is that which is known as "lightning pains," which may be due to disease of the sensory fibres; and in cases of locomotor ataxia it must have struck many observers how strangely pain, hyperæsthesia, and anæsthesia may come and go in certain parts in a way that seems scarcely explicable unless on the hypothesis of local nerve change. In regard to the eye changes, the temporary and passing amauroses, and other symptoms connected with special sense, I may refer to some facts recorded by Dr. Althaus.[1] Having referred to the optic neuritis as being well known in association with Locomotor Ataxia, he gives cases in which the olfactory and auditory nerves were the seat of disease, resulting in alteration or destruction of the functions of these nerves.

It is interesting to know that while, from clinical considerations, I was led to this view of these symptoms, Dr. Hamilton has been led in the same direction by

[1] Althaus "On the Pathology of Peripheral Nerve Disease," American Journal of the Medical Sciences, 1879.

his pathological observations. It has, indeed, long been known that atrophy of cranial nerves occurs in the course of locomotor ataxia, but what I have brought before you to-night is fitted to clear up our conceptions on the matter.

Another point of practical interest is the light that this may be fitted to throw on the beneficial effects of nerve-stretching. The demonstration of such changes as these may be followed one day by proof that some allied change exists in the axis cylinder of nerves in the cases which are benefited by nerve-stretching. And taking together what we have said regarding locomotor ataxia and this plan of treatment, the thought will naturally occur that we may herein find the explanation of the marvellous results of nerve-stretching recently described as having occurred in that disease.

With regard to treatment I cannot as yet speak very positively. Certainly strychnia seems injurious in the early stage and beneficial in the later, while ergot of rye seems to be useful in the early periods. It remains to be seen whether nerve-stretching is applicable or not at any stage. Many remedies may be useful for relieving pain—quinine, salicylic acid, salicylate of soda, morphia. During the period of advance the patient should be kept at rest. When the acute stage has passed, friction, electricity, passive and then active exercise, should be carefully tried.

—

Histology of Spinal Paralysis of Children and Progressive Muscular Atrophy.

MM. ROGER and DAMASCHINO (*Revue de Méd.*, Feb. 1881) contribute an exhaustive paper on this subject, and from abundant evidence arrive at the following conclusions. 1. The characteristic alteration in infantile paralysis is a spinal lesion, causing atrophy of nerves and muscles. 2. Its seat is in the anterior part of the gray matter, and it shows itself as softened patches. 3. The softening is of inflammatory origin, and the lesion is, therefore, a myelitis. 4. Progressive muscular atrophy consists essentially in atrophy of the motor-cells, without any patches of inflammatory softening.—*Lond. Med. Record*, April 15, 1881.

—

Iodine as a Specific in Croupous Pneumonia.

Iodine or iodide of potassium is, according to SCHWARZ (*Deutsche Med. Woch.*, Band vii. No. 2, 1881), a specific in simple uncomplicated croupous pneumonia. If given during the first twenty-four to thirty-six hours from the onset of the initial rigor, it will arrest the further progress of the disease. In illustration of this view, ten cases are recorded in which the crisis occurred before the end of the second stage, and in one case at the end of the first day. The following are the formulæ adopted by Schwarz: Tincture of iodine, five drops; water, 120 grammes (4 ounces); one tablespoonful hourly. Iodide of potassium, 1½ grammes (22 grains); simple syrup, 30 grammes (1 ounce); water, 120 grammes (4 ounces); one tablespoonful hourly.—*London Med. Record*, May 15, 1881.

Steatosis of the Liver.

Upon this subject, to which Prof. VERNEUIL has frequently alluded, he delivered an interesting clinical lecture, at the Pitié, which is reported in the *Gazette des Hopitaux* (March 3), under the heading "Pathological and Physiological Steatosis of the Liver in Large Suppurations and Pregnancy."

I return, he says, intentionally to the case of a patient about whom I have already spoken to you, and who died six days after I had performed amputation of the thigh. I return to the case because we have found a visceral lesion which I had diagnosed during life, and of which you must take account in deciding the

question of operating; indeed, I shall always call your attention to it whenever the opportunity offers itself. This man, whose knee-joint had been opened, and in whom there existed very extensive suppurations, consequent on burns, was condemned beforehand to certain death; and the operation, performed at his reiterated supplication, did him neither good nor harm. Without dwelling on the diseased state of the bloodvessels and the commencing fatty degeneration of the heart found at the autopsy, there is to be noted the fatty degeneration of the liver which is the result of the existence of vast suppurations. Whenever, in fact, you see a patient who has been long in the hospital, a prey to constant and abundant suppuration, seized at a given moment with intense diarrhœa which is not of a renal origin (that is, if no anterior lesion of the kidneys has existed), you may boldly pronounce it of hepatic origin. More than this, if the diarrhœa becomes complicated with œdema of the lower extremities, when there is no disease of the heart or kidneys, this œdematous condition is an additional sign of the hepatic lesion.

I may refer to another patient in the hospital, who is in the same condition as the other, and who in all probability will shortly die. This woman, still strong and vigorous prior to her last confinement, entered the hospital six weeks after that had taken place, with symptoms which were at first considered to be due to phlegmon of the iliac fossa, but which eventually proved to be a deep-seated, ossifluent abscess proceeding from the hip-joint. As in the former case, this woman became pale and wan; she has lost her appetite; both her legs are œdematous; and for some days past she has suffered from an invincible diarrhœa. At the same time the urine exhibits no alteration, and the heart is healthy; and there certainly is here steatosis of the liver, which, on the one hand, is the result of prolonged suppuration, and, on the other, prevents the wound cicatrizing. The patient will finish by sinking from exhaustion. But, in her case, why and how did this steatosis arise? Pregnancy, as is well known, entails a steatosis of the liver which may be termed natural—a physiological steatosis, which disappears with the cause that produced it. This fact is completely recognized and proved by researches made on the females of mammalia; and this normal phenomenon explains the pyogenic tendency of recently delivered women, similar to that of all individuals having a fatty liver. This patient, then, has retained her physiological steatosis—a steatosis which later on became pathological, and which has continued to increase daily since the formation of the abscess, and the suppuration to which this has given rise. This patient will certainly succumb to this fatty degeneration of the liver, whether she dies from exhaustion and famine, or is carried off by some complication supervening at a later period. Such complications in steatosis of the liver most frequently are met with in the serous membranes, which have a great tendency to become implicated, whether it be the pleura or, more probably in this case, the peritoneum.

After recapitulating the phenomena of the two cases in the order of filiation, which is always observed in such, Prof. Verneuil observes that the lesson to be drawn from facts now so well established is to operate as seldom as possible on patients who are subjects of steatosis of the liver, although this is not a formal contra-indication in every case, the exception confirming the rule. Thus, in a case of comminuted fracture of the leg, after every attempt had been made to save the limb in vain, amputation was performed in spite of the well-ascertained existence of steatosis of the liver, which increased proportionally with the suppuration. After the operation, the pus having diminished, the condition of the liver was ameliorated, and the steatosis progressively disappeared as cicatrization advanced.

"Steatosis of the liver thus plays a great part in the results of surgical operations."—*Med. Times and Gaz.*, April 23, 1881.

Surgery.

Treatment of Syphilis by the Subcutaneous Injection of Mercurial Solutions.

M. TERRILLON records (*Bull. et Mém. de la Soc. de Chir.*, 1880, p. 534) the results of experiments made at the Lourcine Hospital with the solution of peptonized mercury recommended by Bamberger. The solution is made as follows: Take a 5 per cent. solution of corrosive sublimate in distilled water, and a solution of chloride of sodium (18 to 20 per cent.) also in distilled water. Dissolve one gramme (15 grains) of flesh peptone in 50 cubic centimetres of distilled water, and filter. To the filtrate add 20 cubic centimetres of the sublimate solution, and afterwards a quantity of the sodium solution (about 15 or 16 cubic centimetres) sufficient to dissolve the precipitate. Pour into a graduated cylindrical vessel, and add distilled water until the whole measures 100 cubic centimetres. Cover the vessel and let it stand for a few days. A whitish flocculent precipitate will form, and must be separated by filtration. The solution will then keep clear for at least three months, and is not precipitated by heat, acids, or alkalies. With this solution M. Terrillon has made 487 injections of 1 cubic centimetre each, containing 1 centigramme (about $\frac{1}{8}$th grain) of peptonized mercury; and 88 injections of about half that quantity. A Pravaz's syringe with vulcanite mounts was used. The dorsal region was preferred for the site of the injection, which was performed slowly, and the diffusion of the solution was assisted by slight kneading with the finger. In no case did abscess occur. The larger dose sometimes caused more or less prolonged pain about the seat of injection; and in one case, after a large number of injections, partial anæsthesia followed. The smaller dose never caused pain or other inconvenience. Salivation was produced in several cases after four or five injections of 1 centigramme repeated daily; and examination of the urine some hours after the injection showed the presence of mercury in it. M. Terrillon reserves his report of the therapeutic action of this mode of treatment for a future occasion, as the patients have not yet been sufficiently long under treatment for a trustworthy conclusion to be arrived at.—*London Med. Record*, April 15, 1881.

—

On the Prophylactic Treatment of Ophthalmia Neonatorum.

Profs. CREDÉ, of Leipzig (*Archiv für Gynäkologie*, Bd. xvii. Hft. 1), R. OLSHAUSEN (*Centralblatt für Gynäkologie*, 1881, No. 2), and D. HAUSSMANN, of Berlin (*Ibid.*, No. 4), agree in the necessity of prophylaxis against this disease, in all lying-in institutions, at any rate, but differ somewhat as to details. Credé commenced by treating the eyes of children born of mothers who had a vaginal catarrh, first with 1–60 boracic acid solution, which failed, and then with two per cent. nitrate of silver solution, following this by washing the eyes frequently for twenty-four hours with two per cent. solution of salicylic acid. Encouraged by his success, but finding that the children of apparently healthy mothers occasionally took the disease, he treated all cases, and instead of washing the eyes with salicylic acid, he secured them for twenty-four hours with a bandage wetted with the solution. By these means he reduced his percentage of the occurrence from 13.6 to 0.5. The single case that went to make up this latter percentage was one where the treatment had been omitted. Olshausen, working at the same subject and at the same time, used a one per cent. solution of carbolic acid, which he pencilled over the eyes after birth, and thereby reduced his cases from 12.5 per cent. to 6 per cent.; but latterly he has commenced treatment before the complete birth of the child, first pencilling the eyelids before they had

been opened, and then washing the surface of the eye with a fresh piece of wadding, 1 per cent. carbolic solution being used for both purposes. In this way he has brought his cases down to 3.6 per cent. He also observes that the cases that have occurred have been much milder than were those before prophylaxis was practised, never going the length of ulceration of the cornea, and frequently only one eye being affected. He suggests that a 2 per cent. solution might be more efficacious. To guard against the infection of a sound from an affected eye, he recommends that the child should always be laid on the affected side, and that its hands should be tied. The use of a bandage he disapproves of. Haussmann, while agreeing with the others, recommends the use of antiseptic vaginal injections, especially in malpresentations and operative cases, as there is then a greater chance of the eyes being partially opened during birth.—*Edinburgh Med. Journal*, May, 1881.

—

Diabetic Cataract.

Dr. Galezowski contributes to the *Recueil d'Ophthalmologie*, August, 1880, an interesting paper on diabetic cataract, with the history of five cases of successful extraction. He commences by remarking that diabetic cataracts are of two kinds, viz., those which depend on the presence of sugar in the blood, but more especially in the aqueous humour; and those which, occurring in diabetic subjects of a certain age, are simple coincidents, and do not stand in the relation of cause and effect. Diabetic cataracts, according to the author, depend on the presence of saccharine matter in the aqueous humour rather than in the blood and tissues, and are more frequently to be met with in plethoric than in thin subjects. As to the consistency of such cataracts, it will vary according as they are simply senile, or are dependent on the presence of glucose, and no hard and fast line can be laid down. From his own researches, he is led to suppose that it is more especially at the posterior segment that diabetic cataracts commence; but they also occasionally arise simultaneously in one or more of the anterior and posterior layers, forming a sort of envelope around a transparent nucleus. As to the prognosis of operation in such cases, it is by no means so desperate as some authors have taught. A very careful opinion must, however, be given as to the amount of sight to be ultimately recovered, seeing that amblyopia, retinitis, atrophy of the papilla, paralysis of the sixth pair, and other complications, occur even more frequently than cataract in diabetic subjects. Thus, in 108 diabetic patients suffering from disturbance of vision, only 37 had cataract. As to the best method of extraction, the author holds that, while for soft cataracts the linear method may be allowed, for the hard, the only proper one is the peripheral flap operation with iridectomy. The author sums up by saying that the existence of glycosuria should not be looked on as in any way a contraindication, so far as an operative interference is concerned; but that in all cases, both before and during the operation, extreme caution and a strictly antidiabetic regimen are necessary.—*London Med. Record*, April 15, 1881.

—

Treatment of Detachment of the Retina.

In an interesting paper on the treatment of detached retina, Dr. Dianoux (*Archives d'Ophthalmologie*, Dec. 1880) insists on the therapeutic value of injections of pilocarpine. He publishes a series of eight cases, in seven of which the improvement which followed this course of treatment was remarkable. The first case occurred in a girl aged 21, very myopic, whose left eye was blind, while the right could do little more than distinguish light from darkness. In the right the retina was almost wholly detached, except a small crescentic portion superiorly.

Within the first week of treatment the improvement was most marked, and continued to increase during nine months subsequently, until, with —10 D, vision was = $\frac{1}{10}$ for distance, and for near objects the finest type was legible. The second case occurred in a man aged 34, the sight of whose left eye had been previously lost by a detachment of the retina. The right eye was subsequently affected, and sight was reduced to counting of fingers at two metres. The inferior and external portion of the field alone remained. Six weeks after treatment vision had improved to $\frac{2}{3}$, and the detachment was limited to the inferior portion of the retina. Within a year vision had become normal; while, although the ophthalmoscope revealed no improvement in the condition of the other eye, vision had in a certain limited degree returned to it. The other cases are in the main similar to the above. In one, however, that of a woman aged 63, the treatment failed completely. In this case, the detachment had existed for three years, and was total, vision being limited to the perception of light. The author, in discussing these results, considers that a series of seven consecutive cases is sufficient to remove all suspicion of a merely fortunate coincidence. In a previous series of thirty detachments, treated by various methods, he had had but one case of cure. The drug acts as a derivative on the eye, probably by means of its action on the salivary, lachrymal, and other glands. Its action is rapid and prolonged, as, in all the cases in which it was beneficial, improvement took place before the tenth injection, and continued for months. The injections should be administered so as to keep the patient as long as possible under their influence. They should be used daily during ten or fifteen consecutive days, followed by a period of rest of ten days. This method should be persevered in, until it is evident that a stationary condition has been arrived at. The injections should be in sufficient doses to cause a copious salivation of at least an hour's duration. In most of his cases, the author commenced with six drops of a solution of twenty centigrammes of nitrate of pilocarpine to four grammes of distilled water (= 5 per cent. solution). The injection should be administered on an empty stomach to avoid vomiting.—*London Medical Record*, April 15, 1881.

Desquamative Syphilis of the Tongue.

M. PARROT has recently drawn attention (*Le Progrès Médical*, No. 11), in a clinical lecture with the above title, to an important and somewhat novel form in which hereditary syphilis sometimes manifests itself.

At the tip of the tongue, or along its edges, a small patch, from one to half a millimetre in diameter, shows itself; it is white, rounded in form, and on the surface of it the epithelium is somewhat thicker and whiter than normal. Very shortly, within twenty-four or twenty-six hours, in the place of this milk-like disk there appears a whitish ring circumscribing a red surface—the centre of the patch—where the epithelium is shed, and the papillæ are visible. From this time the affection spreads with remarkable rapidity, either towards the posterior parts of the tongue or towards its centre.. The circles transform themselves into crescents or irregularly curved lines, the concavity of which is almost uniformly forward. This modification in the form of the disease is due sometimes to its attacking the borders of the tongue, where its eccentric course is arrested (for it rarely attacks the under surface), and sometimes to the coalescence of several crescents. In the latter case the surfaces which have most recently desquamated are limited by a kind of festoon. Each patch presents certain characteristics which deserve mention. At the periphery and along it there is to be seen a zone of a dead-white colour, which distinctly demarcates both by its colour and elevation between the portions of the tongue which have and those which have not

been attacked. As regards the desquamated surface, this is found to vary in different parts; close to the epithelial zone, where the disease is most recent, the tongue is smooth and of a vivid red colour; while farther away this condition, though present in some degree, becomes less and less manifest until it shades off into the healthy appearance.

However rapid or active this affection may be, it is very rare for the entire tongue to be desquamated by one of these patches; there nearly always remain, either behind or in the centre, some points which are not affected. Nevertheless, before one patch has completed its course, another one shows itself, and takes the same direction. In this way sometimes no less than three desquamating zones may be observed gradually spreading from the tip to the posterior region of the organ, not unlike the concentric successive undulations which may be seen on the surface of water after repeated shock of any kind.

The duration of the disease, considered in its *ensemble* or in any one of its stages, is very difficult to determine. The latter rarely lasts five or six days. The disease may remain dormant for several months, perhaps years, only to break out afresh during some period of activity, or under influences which up to the present time M. Parrot has not been able to formulate.

The diagnosis is simplified by this consideration—that the disease belongs essentially to childhood, though it is impossible to say that it may not also affect adults. The appearances are so peculiar and so typical, at whatever period observed, that it is impossible to mistake the affection after having once or twice attentively watched it. The scarlet fever tongue, in contradistinction, is despoiled of its epithelium very rapidly and over its whole surface. It is of such an intense red that one might think it would bleed if touched. Thrush also gives rise to desquamation, but very irregularly and not at all after the manner, in zones, just described. Besides, a microscopic examination, however rapidly made, would at once discover the spores and scolices of the parasite. Aphthæ cause not only simple desquamation, but also veritable ulcers sometimes, which, however, rarely extend beyond their first limits.

And as regards other affections of the tongue, such as pityriasis, lichen, psoriasis, or opaline syphilitic *plaques*, on which authors are at present far from agreed, and the signs of which are but badly defined, they may be left out of the question, as they are never found among young children. The pathological anatomy of the disease has yet to be determined. M. Renaut, of Lyons, on examining the scrapings of a tongue affected in this way, found a large quantity of epithelial cells, sporules, coagulated mucin, and embryonic cells in abundance. Such an examination, however, could not of course determine either the seat or the nature of the lesion. M. Martin, chief assistant in M. Parrot's laboratory, has examined microscopic sections of three tongues. From these it was found that the epithelium was tumefied and thickened. The cells of the corneous layer were increased in volume, as well as those of the Malpighian layer, which latter is further in a state of active cell-proliferation. There is also a large number of lymphoid corpuscles in the papillæ and adjacent portions of the derma, either scattered or in groups. M. Parrot thinks from these appearances that the derma is the principal and primitive seat of the affection, and that the superficial manifestations—the only ones visible during life—are secondary and consecutive.

As to the nature of the affection, M. Parrot thinks that it is certainly not parasitic, nor due simply to mal-assimilation, but that it is a manifestation of congenital syphilis: for of thirty-one cases, in no less than twenty-eight were the signs of this disease incontestable. Of these thirty-one cases, not less than twenty-two occurred in children of two years and under, while at from two years to six there were only nine. This is exactly the period when congenital syphilis

is most active. The disease has manifest analogies with skin syphilis, which occurs in patches, with more or less concentric edges, which desquamates, and not infrequently occurs in successive crops, and which microscopically resembles closely the appearances above described in the tongue.

Why, of the whole buccal cavity, should the tongue alone be attacked? M. Parrot thinks because of its richness in nerves and bloodvessels, and of its great activity—conditions which favour diathetic manifestations. He thinks this affection is not contagious by contact, for there is neither erosion nor secretion, and the majority of the subjects attacked have passed the age when the disease is contagious.

The prognosis and treatment do not call for any special remarks, the indications being general rather than special.—*Med. Times and Gazette*, April 23, 1881.

—

Excision of the Tongue.

Mr. WILLIAM STOKES, of Dublin, at a recent meeting of the Clinical Society of London (*Lancet*, April 30, 1881), read a paper on this subject. He commenced by alluding to the change that surgical opinion has lately undergone in reference to the merits of excision of the tongue, and mentioned the views of Professor Gross and Mr. Collis on this subject. The particulars of six cases in which the writer had excised the tongue were then briefly stated, in which relief from suffering caused by enlargement of the tongue, difficulty of deglutition and articulation, discharge and pain, was obtained in all as an immediate result of the operation. In two of the cases a considerable time—twenty-two months and eighteen months—elapsed without any recurrence of the disease; in two others three months and four months elapsed; in one the patient was lost sight of immediately after the wound healed, and in only one of the cases was almost immediate return of the disease observable. Performing the operation at an early period of the development of the disease, if possible before glandular complications, was strongly advocated, and Sir J. Paget's views stated, as regards the small risk attending the operation.

The question of unilateral or bilateral ablation was then discussed, and the advantages of the latter pointed out. The question of what is the safest and best method of excision was then considered, as well as the two special dangers of the operation, hemorrhage and septic complications. The author observed that removal of the tongue by a cutting operation is not only more liable to be followed by hemorrhage, but also by septic infection, the outcome of which latter is in a large number of cases either pulmonary gangrene or septic pneumonia. These are not observable at all to the same extent in the cases operated on by the écraseur. In proof of this, the statistics of Dr. Scheffer and Mr. Collis were considered, in the former of which it was found that the percentage of mortality from septic causes in the cases operated on by incision reached the startling figures of 50, and in those of Mr. Collis 61. Mr. Barker's cases were also alluded to, but the number of cases (3) operated on by incision, in which there were no septic consequences, was not considered sufficiently large to materially affect the conclusions arrived at.

The disadvantages of certain of the écraseur operations were then pointed out, and the author concluded by describing the method of operating he preferred. He commences by transfixing the cheek at a point corresponding to the last molar of the lower jaw, and makes an incision downwards and forwards towards the angle of the mouth, terminating a few lines above it. All bleeding vessels being secured, and the parts retracted, a ligature is passed through the tip of the tongue to facilitate the drawing forwards of the organ by an assistant. This being

done, a straight Liston's needle, armed with a double strand of carbolized silk, is passed through the base of the tongue at a point behind the foramen cæcum. In front of this the chain of an écraseur is passed round the tongue, and the organ gradually severed. This portion of the operation is done very slowly, taking from thirty-five to forty-five minutes. The author never witnessed in any of his cases any secondary hemorrhage, immediate or remote. The wound in the cheek is then brought together by a few points of interrupted suture. The free ends of the strand of silk passed through the base of the tongue are then fastened temporarily, by adhesive plaster, to the side of the cheek or forehead. This double thread, which, in the event of secondary hemorrhage or traction, would be of much assistance in enabling the surgeon to draw forwards the base of the tongue and secure the bleeding vessels, is removed usually on the third or fourth day after the operation. The author believed that, by the use of the écraseur employed in the manner he described, coupled with antiseptic measures during the healing of the wound, the operation is attended with little pain, with the minimum of risk as regards either primary or secondary hemorrhage, or those septic troubles which, after all cutting operations, are so fruitful a means of raising the mortality attending this important operation.

Mr. HEATH said that in this country the tongue was more freely operated upon than was assumed by the author. As to the question of growth after removal, in Mr. Barwell's case there was a considerable increase; and in his own case, where more than half was removed, the stump of the tongue nine years after appeared to have enlarged. The mode of operating was different in different cases. He had now entirely given up the galvanic écraseur, in favour of the chain écraseur, and had never found occasion either to pierce or incise the cheek; for, by bending the écraseur and pulling forwards the tongue, the instrument could be applied far back. Whether a unilateral or bilateral operation should be performed depended on the merits of the case; and he agreed with Mr. Baker that a unilateral operation should be done when necessary; it also enabled the surgeon to examine the two halves of the organ when split in the median line.

Mr. MORRANT BAKER advocated the unilateral method when the disease was sufficiently limited. The median incision avoided the severance of arteries and rendered the detachment of the organ more easy, and it allowed of removal of the other half if the disease were found to encroach near the median line. He thought division of the cheek might be more often done with advantage, especially when the disease extended far back. It allowed also of a better control of hemorrhage. He thought the tongue could not grow after incision, but that an apparent increase in size might result from the contraction of the cicatrix. And as to the retention of speech, it must be remembered that the tongue was not wholly removed when only the portion in front of the foramen cæcum was excised. When completely removed, the mouth has a very different appearance; there is a large hollow in the place of the root of the tongue, and the arches of the palate are approximated. Mr. Gant had recently exhibited a case of nearly entire removal, which had been effected much on the plan adopted by Collis. That patient could hardly articulate. Mr. Baker had not himself found tracheotomy necessary; but in a case where he assisted, tracheotomy had to be done on account of blood flowing into the trachea. A fresh hemorrhage occurred just before the removal of the tongue was completed, and the blood flowed more readily into the trachea than when there was no tube in it. Of course it might be said that the pharynx should have been plugged.

Mr. MACCORMAC pointed out that the trachea itself might have been plugged. He asked Mr. Stokes what measures had been taken to remove the diseased glands, which occurred in some of his cases. Permanent success depended upon

this. Any modification of the operation, by splitting the cheek, etc., was justifiable if it facilitated the removal of the diseased tissues in the floor of the mouth. The difficulty of removal of infiltrated glands was considerable, and he should like to know whether the plan followed by Mr. Stokes enabled him to effect their removal. He was surprised to learn that an operation producing a crushed and bruised surface (as did the écraseur) is followed by less risk of septic processes than a simple cut wound. However, the fact remained. He had once or twice divided the tongue without any hemorrhage of moment occurring.

Mr. BARKER said that the list he had furnished to Mr. Stokes somewhat altered the relative rate of mortality after different methods of operation. At University College Hospital, from 1871 to 1879 inclusive, there had been 51 cases of lingual epithelioma, in 34 of which excision was performed. 11 of these cases died in consequence of the operation; 5 from septic pneumonia, 2 from septic bronchitis, 2 from septicæmia, 1 from pyæmia, and 1 from œdema of the glottis. A large proportion thus died from septic causes. Of these cases 25 were operated on by the galvanic écraseur, with 9 deaths; 7 by the wire écraseur, and 1 death (from pyæmia); 3 by the knife, no deaths; and 1 by ligature, fatal (from septicæmia). These figures, although few, condemned the galvanic écraseur. Did Mr. Stokes include the galvanic écraseur in his statistics? Mr. Barker agreed with Mr. MacCormac as to the preference to be given to the knife. The tongue should be split in the median line, and the base cut across, this measure allowing of the ready control of bleeding vessels and of their ligature in the ordinary way, and was far less open to danger of septic trouble than after crushing. Tracheotomy was sometimes called for in cases where much hemorrhage was to be anticipated, or the diseased tissues were of wide extent. The risk from hemorrhage could then be met by plugging the trachea, or by means of a sponge in the pharynx. In three cases he had no trouble in retaining a sponge there; but if the trachea were to be plugged, Trendelenberg's tampon should be used, care being taken in its inflation, since, as Dr. Semon had shown, its over-inflation caused dyspnœa.

Dr. DOUGLAS POWELL asked Mr. Barker what was meant by "septic" bronchitis and "septic" pneumonia. Did he imply that in such cases there was general septic infection; and were other organs affected, as in such septicæmia? If there were only bronchitis or pneumonia, that might possibly be produced by the passage of irritant matter into the bronchi or lung, and would be met by measures preventing such gravitation.

Mr. T. SMITH asked whether Mr. Stokes made any incision in the sublingual tissues. He believed that only a portion of the tongue could be pulled forward, and that the organ could not be wholly removed unless the subjacent tissues were divided. As he understood it, the septic pneumonia of these cases is produced by blood, etc. trickling down the air-passages. The discharges were more copious after the use of the galvanic écraseur, owing to the slough it produces.

Mr. MARSH, in two or three instances of unilateral excision, had been disappointed with the result, the longitudinal cicatrix holding the tongue down, and the muscles of the remaining half turning it over, a condition giving rise to discomfort. It was plain that opinion was adverse to the galvanic cautery. He was acquainted with cases of secondary hemorrhage following its use, and with one or two of fatal complications. By first dividing the muscles attaching the tongue to the lower jaw the base of the epiglottis can be reached. The experience of St. Bartholomew's Hospital did not accord with the statistics given by Mr. Barker.

Dr. COUPLAND urged Mr. Barker to reply to Dr. Powell's question. In post-mortem examination of cases of cancer of the tongue, foci of broncho-pneumonia

were common, and to be attributed, not to septic infection in the ordinary sense, but to the inhalation of irritant and putrid materials.

Mr. BARKER said the question was an important one. No doubt sometimes there were pulmonary abscesses of truly pyæmic (embolic) kind; but the lungs might be also affected by blood trickling down the trachea during the operation, or fetid discharges similarly passing; also, he believed, by the simple inhalation of very acrid emanations from these wounds. In one instance the house-surgeon and nurse in attendance on the case became affected with sore throat. He did not think these different modes of lung complication should be confused.

Dr. POWELL said the point was one of great practical importance. He had asked if there was any evidence of general blood-poisoning to which the lung disease was secondary. If in all such cases the infection was local, then a remedy might be sought in antiseptic inhalations and in enforcing a prone position, so that the blood and discharges might not pass down the air-passages.

Mr. BARKER said that in one case there was distinctly a general pyæmia, developing long after the operation, with abscesses in the liver and in the vicinity of the kidney, as well as the lung. In the other cases there was no involvement of other organs.

Mr. STOKES in reply said, that he had not included Mr. Barker's statistics in his lists, but he had made a percentage mortality of about sixty in the cases of simple excision by the knife; and he admitted that it was remarkable that there should be apparently less danger from septicæmia in such cases than in those treated by the cautery. He was glad to find Mr. Marsh preferring the bilateral method, and could indorse what he had said as to the greater inconvenience both as regards deglutition and articulation resulting from one-half of the organ being excised than when both sides are removed. He knew of one case where the patient came to have the other half removed because of the difficulty in articulation and because it kept getting between his teeth. He was also pleased to hear Mr. Barker suggesting a preliminary division of the cheek, which greatly facilitates the operation. He had performed division of the sublingual tissues in such cases where the thickening and enlargement of the tongue called for it.

—

Extirpation of the Larynx for Malignant Disease.

Dr. WHIPHAM and Mr. PICK communicated to the Clinical Society of London (*Lancet*, April 2, 1881), a case of extirpation of the larynx for a growth originally affecting the left ventricular band and vocal cord, which subsequently involved the whole larynx.

The patient, a commercial traveller, aged thirty-nine, consulted Dr. Whipham on May 27, 1876, on account of huskiness and a constant desire to "clear the throat," which had come on suddenly and without apparent cause. He had been previously free from all throat affection, and there was no history of syphilis. The man was very nervous, and it was not till June 8 that a view of the larynx was obtained. It was then found that a warty-looking growth rather larger than a pea arose from the anterior part of the left ventricular band and vocal cord. After repeated examination and the passage of brushes into the larynx, with a view of preparing the patient for operation, his nervousness was so far under control on July 29 that two small portions were removed by evulsion, with great relief to the huskiness. The case was constantly under observation, but no further operative interference was required until March 3, 1877, when three pieces of the tumour (which microscopically presented for the most part the appearance of papilloma, but in which at one or two spots there appeared to be a tendency to the production of epithelial cells) were removed by the forceps. The whole of

the warty portion was removed at this time, but the vocal cord was thickened generally; the voice recovered tone to a great extent. Subsequently, however, it was found necessary to apply the forceps to a recurrence of the growth on several occasions—viz., June 16, 1877; January 5, 1878; March 23, 1878; April 19, 1878; December 31, 1878.

Early in 1879 the patient had a severe attack of catarrhal laryngitis, and on June 23 in that year he complained of having lately suffered from great dyspnœa, with tenderness over the thyroid cartilage and some external swelling in this situation. He was admitted into St. George's, and in the course of the following six weeks several pieces of the tumour were removed. Again in October, 1879, a large piece was taken from the larynx. By March, 1880, a great change had occurred in the state of the parts; the growth involved the whole ventricular band and vocal cord; the left ala of the thyroid cartilage was pushed outwards, and was tender; dyspnœa being at times urgent. Towards the end of April, the dyspnœa threatened suffocation, and Mr. Pick, after examining the patient, performed tracheotomy, from which the recovery was perfect. During the next six months the disease progressed rapidly, the whole larynx being involved by the middle of October, when a large lobulated mass was felt in the position of the left ala of the thyroid cartilage. In the early part of November, 1880, some hemorrhage occurred through the tube, and at the end of the year he was readmitted into hospital with a view to the performance of some operation. Shortly after his readmission this hemorrhage recurred rather freely.

After consultation with his colleagues on the previous day, Mr. Pick proceeded to extirpate the larynx. Having introduced a tampon canula, Mr. Pick made an incision on January 16, 1881, two and a half inches in length in the median line of the neck, and a second incision at right angles to it across the middle of the thyroid cartilage. On reflecting the skin the growth was found to involve the left ala of the cartilage. The thyroid cartilage was then divided vertically in the median line, and the two halves separated, when the whole larynx was found occluded by the growth. The left ala was removed, and subsequently the right also. The cricoid, with the remains of the arytenoids, were then freed from their attachments, and removed, and finally the epiglottis, which was involved in the disease, was cut away. The wound was carefully explored, and all traces of the growth as far as possible were removed. No vessel required ligature. The operation occupied three-quarters of an hour, and the patient was not much exhausted at its close. The wound was plugged with sponges. Slight hemorrhage occurred after the operation, which was arrested by the introduction of an additional sponge. Nutrient enemata were ordered every four hours, and for the first two days the patient's progress was satisfactory. On the third day, however, his temperature rose to 103.2° F., and his skin became dry; his pulse ran up to 142. On the fourth day he complained of severe pain about the ensiform cartilage; his expression became anxious. Rapid exhaustion set in, and he died on the morning of the fifth day after the operation. At the autopsy, right pleurisy and pericarditis, presumably pyæmic, were the chief lesions found.

Among the many points of interest in the case, the following were brought before the notice of the Society: 1st. That for three years the microscopic appearances of the growth were for the most part those of papilloma. 2d. That the duration of the disease (four years) was rather in favour of its having been an innocent growth in the earlier stages, although microscopic examination showed that, even at the onset, there was, in one or two places, a tendency to epithelial proliferation. 3d. That the above facts, and the limitation of the growth to the larynx, were favourable to the success of the operation of extirpation. 4th. That if the operation had been undertaken as soon as the malignant aspect of the dis-

case became manifest, success might have been the result. 5th. That the plan of dividing the thyroid cartilage and removing each half separately is preferable to the method adopted by Dr. Foulis of removing the larynx entire, and for these reasons: (1) that by separation of the alæ a good view of the extent of the disease is obtained at an early period of the operation; and (2) there appears to be less danger of wounding important structures.

Dr. SEMON was gratified that Mr. Pick had found his modification of Trendelenberg's tampon canula useful; and he drew attention to the liability to dyspnœa being caused by over-inflation of the tampon. This occurred in a case of thyrotomy he had recorded, and was attributed by him to pressure upon the tracheal branches of the vagus nerve. Similar attacks occurred in two cases by Dr. Bosworth, and also in one by an Italian surgeon, and another by an English surgeon. The dyspnœa at once ceased on allowing some of the air to escape from the tampon. In Mr. Pick's case there could be no doubt that the disease was epitheliomatous at the time of operation. Extirpation of the larynx was not necessary for papillomata, which could be removed by endo-laryngeal operation or by thyrotomy. He believed that for a simple growth to become malignant there must be a constitutional tendency to malignant degeneration, which would manifest itself whether the growth had been interfered with or not. To show what may be done by persistent endo-laryngeal operation, obviating recourse to the formidable operation of extirpation, he quoted a case recently published in the *Berlin. Klin. Wochenschrift.* It was a child eleven years old, in whom a papillomatous growth had been removed by thyrotomy, sub-thyroid laryngotomy, and thyrotomy again, with invariable recurrence; extirpation of the larynx was advised, but declined; and for six months Dr. Bucher persistently treated it by endo-laryngeal methods, so that he succeeded in completely removing the growth. Fifteen months later the child was free from the growth. In fact, papillomatous disease does not give any indication for extirpation of the larynx.

Mr Pick agreed that extirpation was not called for so long as the growth could be removed by the forceps. In this case it would have been better to remove the ala of the thyroid when the tracheotomy was done, for the growth had already perforated the cartilage.

—

First Endolaryngeal Operation during Anæsthesia.

By this operation, the successful removal of a papilloma laryngis from the larynx of a boy eight years old, under the influence of ether, Prof. SCHNITZLER has shown for the first time that an anæsthetic may in certain circumstances be used during endolaryngeal operations.. Prof. Schnitzler describes (*Wiener Med. Presse*, 1880, Nos. 48, 49) the operation as follows: "An assistant seated opposite me took the boy on his knees and held him fast. Ether was then administered. So soon as the boy was narcotized, an assistant opened the mouth with a suitable dilator, drew forward the tongue with a forceps, and, taking hold of it with his left hand, held it so that I could not only pass the laryngoscopic mirror conveniently into the throat, but could also direct into the cavity of the mouth by means of a reflector on my forehead, the light of a gas flame situated on the patient's right. Holding the mirror with the left hand, I introduced the laryngeal polypus forceps with my right, and, notwithstanding the secretion collecting in the throat, I succeeded in rapidly seizing and extirpating the new growth." A slight recurrence was readily removed by the application of caustic. —*London Med. Record*, April 15, 1881.

Extirpation of the Thyroid Gland.

Dr. RICHELOT (*Annales des Malad. de l'Oreille, du Larynx, etc.*, Dec. 1880) reports a case in which he removed this gland for "colloid goitre," associated with dyspnœa, in a woman aged 25. The first commencement of the tumour was at the age of 11 years, with great increase between the ages of 15 and 17. Six years before admission, M. Gosselin employed puncture, with the application of caustics and drainage. The tumour on examination was of the size of half a fist, the central lobe being especially large, hard, and non-fluctuating. There was habitual dyspnœa, with dysphagia and weakness of voice. Whilst the patient was in the hospital there was an attack of subacute thyroiditis, after cessation of which the operation was undertaken. The gland was removed through a curved incision with its convexity downwards, extending to the common carotid on each side, and passing immediately above the sternal notch in the median line. The trachea was found strongly curved to the right and slightly flattened from before backwards, but not softened or degenerated. It was intimately adherent to the gland, from which it was removed from below upwards. There was very little loss of blood during the operation. Silk ligatures, which were first employed, were mostly replaced by catgut ones, and the wound was united by wire sutures. There was severe dysphagia for several days, followed at the end of a week by an attack of bronchitis and tracheitis. The result was complete cicatrization of the wound in the fifth week, accompanied by complete and persistent aphonia.—*London Medical Record*, April 15, 1881.

Statistics of Mammary Cancer.

Not long ago we drew attention to some of the clinical aspects of cancer of the female breast, and especially as to its causes. We now propose to speak of it as seen in the post-mortem room, and of the metastatic deposits (verified after death) which occur in different organs, and which give to this disease one of its most terrible characteristics. Drs. TÖRÖK and WITTLESHÖFER have recently analyzed the statistics of the Viennese Pathological Institute from 1817 to 1879, including the post-mortem reports of no less than 72,000 bodies. The results of this exceedingly interesting study are given in *Langenbeck's Archiv für Klinische Chirurgie*, vol. xxv., page 873 *et seq.*, and from it we extract the following as relating to mammary cancer. Of the 72,000 bodies of both sexes, 366 were reported to have died with cancer of the breast, *i. e.*, about ½ per cent.; of these, in eight cases only was there any doubt as to the diagnosis. Of course the figures can only have a relative value, for it is quite probable that breast-cancer is a more frequent cause of death than appears, seeing that cases not adapted for operations would not be admitted, while many might be discharged after admission, as incurable cases. In 351 cases the affected side is given—161 cases right, 144 left, and 46 on both sides. Several authors seem to have noticed this fact, and associate it with the more frequent occurrence on the right side of diseases predisposing to cancer, such as puerperal mastitis. Of these cases (366) only three were males. As to the age at which death occurred, the results correspond very nearly with the clinical deductions of Dr. A. Winiwater. Between twenty-five to forty-five years, 29 per cent.; forty-six to fifty-five years, 34 per cent.; over fifty years, 37 per cent. From these percentages the authors framed the following rule for practice: The less the age seemed to render an operation advisable, either in consequence of special circumstances, or because of the shock of the operation, the greater the number of cancer deaths at that age. In estimating the value of an operation, attention was given to the occurrence of metastases (*i. e.*, of metastatic deposits) in those who had undergone operation and in those who were not ope-

rated on; for the operation can be considered advantageous then only, when it makes a radical cure of the disease possible. The following figures show how this stands:—

Operated . .	184	With metastatic deposits .	79	—
		Without " " .	—	105
Not operated . .	182	With metastatic deposits .	141	—
		Without " " .	—	41
	366		220	146
			366	

It follows, therefore, that operation in 146 cases would have allowed of complete removal of the carcinoma. A further proof of the great value of early operation is afforded; for otherwise there is always a chance that metastases may have occurred.

Coming to the subject of the secondary growths, reference is just made in support of the common belief that in the generalization of cancer, before the outbreak actually takes place, a local proliferation in the immediate neighbourhood of the primary growth frequently occurs, either as a direct outgrowth, or in the form of new deposits. To this local dissemination is shortly added induration of the nearest lymph-glands, through which the cancer-cells first get into the lymph-stream, and thence into the various internal organs through the blood-current. Thus, in considering secondary deposits of cancer, it will be well to divide the subject into three stages—local infection, lymph-gland infection, and infection of internal organs. Local infection is where the cancer spreads by direct continuity. Among the 366 cases, there were 192 of local infection. Of these the skin of thorax 148 times, skin of abdomen 5, pectoral muscles 58, intercostals 22, ribs 29, sternum 20, clavicle 3, anterior mediastinum 4, pleura 25, pericardium 2, peritoneum 2, liver 2. Thus it will be seen that the skin and subcutaneous tissue were affected in about three-quarters of the whole cases; while the pectoral muscles were much less frequently so. Thus the ribs and the pleura, and in about an equal number of cases, which must be regarded quite as exceptional and accidental, the pericardium and peritoneum. Of the 148 cases above given, in which the skin was affected, there was ulceration in 110 cases, and in 38 there were disseminated nodules near the original growth. If the entire number of cases (192) of local dissemination be considered in its relation to axillary glandular affection, and metastases in internal organs, a very similar percentage is found both in those with ulceration and those in which there was no ulceration: thus there were about 73 per cent. of cases of internal metastases in each group; while the axillary glandular affection was present in 44 per cent. of the cases with ulceration, and in 59 per cent. of the group without ulceration. If the two groups, however, taken together, be compared with the cases in which there were no secondary local growths, then in only 45 per cent. of the cases were internal metastases present, and only 42.5 per cent. of axillary glandular implication. Thus it would seem that internal metastases are much more frequent in cases where local recurrence takes place, than in cases in which there is no such recurrence. And thus one is led to believe that the cells of a rapidly growing cancer more easily find their way into the blood and lymph currents, and so into internal organs, where they set up metastatic growths, than would the cells of a more purely local, and probably slower-growing, growth.

As regards the affection of the lymph-glands, it has generally been taught that this is the first stage of a general infection; for, in accordance with our present views, the generalization of cancer takes place through the lymphatics; hence the

bsence of glandular affection—other things being equal—is always thought to be favourable omen. In this particular, however, the results of the present inuiry do not agree, for they show that in the 366 cases, axillary glandular affecon was present in only 175 cases, with internal metastases in 57.7 per cent., hile in the remaining 191 cases without axillary affection there were 62.3 per ent. of internal metastases. Of course, it is possible that these figures are not ccurate; for the glandular swelling may have been overlooked, or it may accientally have escaped being recorded. The affection of other glands—cervical nd supraclavicular,—as is well known, is very much below that of the axillary lands; thus, in the cases now under consideration, it is only recorded in 6.3 per ent. of the total. The relative frequency with which internal organs are secondrily affected has been variously given; but a consideration of the cases before , when tabulated, points with great force to the lymphatic, respiratory, and gestive tracts as the "seats of election." All organs which are rich in blood nd in lymphatics—such as the lungs and liver—are specially predisposed to etastatic disease. The bones, genital organs, and central nervous system are ss liable to be infected with secondary deposits. The urinary apparatus is still ss often infected; while the skin and muscular system are much more generally fected by direct continuity of growth. The organs of sense sometimes suffer; ut these cases are extremely rare.

We have only been able to give a brief *résumé* of this interesting paper, to the iginal of which we would refer the reader who wishes for further details. On e whole, the result of this post-mortem research tends to confirm the conclusons which have gradually been arrived at from the many clinical studies on the bject that have been made; and on this if on no other ground it is extremely teresting.—*Med. Times and Gazette*, March 26, 1881.

Final Results of Operations for the Radical Cure of Hernia.

Braun communicates (*Berl. Klin. Woch.* Nos. 4, 5) the results of nineteen ch operations performed by Professor Czerny on sixteen patients. The indiations for radical operations were: 1, strangulation; 2, impossibility of keeping the hernia with a truss; 3, adhesion of the hernia, preventing its return; and, fecal fistula in the hernial sac. One case died from pyæmia; another from onvulsions independent of the operation. Ligature of the neck of the sac and ture of the hernial aperture was done in nine inguinal herniæ, and in two omenl herniæ in the linea alba. Six inguinal herniæ in adults recurred, but remained nall and could be kept up with a truss. One child had remained cured for ree years. Partial constriction of the sac with suture of the hernial aperture as done in two children, and in both cases the hernia returned. The hernial perture alone was closed in two adults and two children. In both adults the ernia recurred, and also another inguinal hernia appeared on the other side. he children remained cured nineteen and thirty-four months. The neck of the c alone was ligatured in an adult, and a small local recurrence took place.—*ondon Med. Record*, May 15, 1881.

Treatment of Aneurism by the Elastic Bandage.

At a late meeting of the Surgical Society of Dublin, Mr. Wheeler communicated two cases of popliteal aneurism cured by the elastic bandage. The first ase was that of a man aged thirty-seven years; the tumour being as large as a nall orange. In that case the blood was "locked" in the aneurismal sac, the imb being bandaged from the foot up to the inferior margin of the aneurism; nd a second bandage was applied, commencing at the superior margin of the

tumour. The compression which was made with the elastic bandage was borne for sixty-five minutes; a tourniquet was then applied over the femoral artery, and the bandage gradually loosened. Pulsation returned in the sac, but not so forcibly as before, and the tumour felt more solid. In the evening, the bandage was reapplied in a similar manner, and in a little more than half an hour the compressing band was removed with the same precautions. The pulsation had then ceased; but compression, by means of a tourniquet, was exerted over the femoral artery for some hours after, to moderate the flow of blood. The second case was that of a young gentleman aged twenty-three years. The tumour was in the right popliteal space, and seemed about the size of a walnut. The only history as to its causation was over-exertion when playing cricket. He was of a nervous and excitable temperament. A somewhat similar mode of treatment was adopted in that case. The limb was elevated for a few minutes before applying the bandage, which was done continuously from the foot upwards, but very lightly over the aneurism. On removal of the bandage in forty-five minutes, all pulsation had ceased. The tumour was solid, and in five weeks after had almost completely absorbed.

Mr. TUFNELL said that he had had an opportunity of examining the first case mentioned by Mr. Wheeler, and that the result was most satisfactory. A question arose as to whether it would be safe to adopt that line of treatment in the country, where the surgeon might not have the patient under his immediate observation.

In reply, Mr. WHEELER said that he had been particular to state that, in both cases, he had applied compression to the femoral artery before removing the elastic band, which was, moreover, done very gradually. Lest the sudden return of the blood might damage the recently formed coagulum in the sac, he was of opinion that it would be advisable to compress the main artery, either by digital or instrumental means, before applying the bandage, for the cure of aneurism in persons advanced in years, in order that the collateral circulation might be somewhat established.—*British Medical Journal*, April 16, 1881.

Iodoform as a Dressing in Tuberculosis of the Bones and Joints.

Dr. MIKULICZ (Vienna) at the recent Congress of German Surgeons read a paper on this subject. Mosetig had published a report of twenty cases, in which, no antiseptic precautions being used, wounds were treated by simply sprinkling iodoform on them, whereby their course was rendered quite aseptic, and the so-called local tuberculosis was healed. In consequence of this, the remedy had been used in Billroth's clinic since the beginning of the year, with a similar striking result. Wounds made in the extirpation of tumours, when sprinkled with iodoform, and covered with a dressing of cotton-wool, healed without secretion, just as wounds heal by granulation under a scab; ichorous sores, under the influence of this remedy, soon lost their putrid smell, and rapidly became clean; tubercular processes also, in the skin, as well as in the joints and bones, were definitely healed by this treatment. The remedy is especially to be recommended in wounds connected with cavities, which come into contact with readily decomposed fluids; as after extirpation of tumours of the pharynx and tongue. In cases of suspected tubercular disease of joints, the injection of an ethereal solution of iodoform appears to be sufficient. If, however, fistulæ be present, the primary focus must be exposed, scooped out, and filled with iodoform; and the fistulæ themselves must be treated with iodoform and gelatine bougies. For injection, an emulsion of iodoform with mucilage of acacia and water is recommended, or a solution of 1 part in 10 of ether, or

1 in 5 of ether and 5 of oil. Iodoform does not excite any influence at a stance; so that, while very severe local disorders may be healed, death may cur from tubercle of internal organs. Hence the constant contact of iodoform ith the diseased granulating surfaces appears to be necessary. Lupous ulcers al rapidly under iodoform, without previous scraping. According to the re-arches of Mikulicz, the antiseptic action of iodoform is small but constant; is explains the necessity of its constant contact with the granulating surface. doform does not prevent the formation of micrococci in blood and serum, nor bacteria in Pasteur's fluid. Its active principle is iodine, which in the tissues transformed into iodides of potassium and sodium. Toxic symptoms occur ly in cases of large wounds, and are of short duration. Dr. Gussenbauer could nfirm the excellent action of iodoform, which he placed before all other known tiseptics as a means of producing healthy granulations. In nineteen cases of berculous affections, he had hitherto met with seven rapid recoveries. In a se of extensive tuberculous ostitis of the tarsus, he had poured a large quantity iodoform into a cavity in the os calcis, with the result of producing a high ptic fever, which soon passed off. The case was still under treatment. A nilar affection of the carpus was healed, with retention of free action in the nt.—*London Med. Record*, May 15, 1881.

Resections of Joints and Antiseptic Dressings.

In a recently published memoir (*Revue Mensuelle de Méd. et de Chir.*, No. , 1880) M. OLLIER points out in the first place that the value of the antiseptic thod in resections of joints varies according to the nature of the indications for e operation. The category of what are called orthopædic resections, the sole ject of which operations is the restoration of the form and function of an anchy-sed joint, has profited the most from antiseptic practice. In recent times, and ce the introduction of the antiseptic method, the indications for operation on formed joints and distorted bones have multiplied to such an extent that this apter of surgery, M. Ollier states, requires now to be wholly rewritten. With gard to the utility of antiseptic dressings, on the other hand, in cases of trau-atic and pathological resections, it is necessary, in order to appreciate this, to stinguish whether such operations are performed for suppurative or for non-sup-rative lesions. In the class of non-suppurative lesions, comprising recent ticular fractures, plastic osteo-arthritis of rheumatic or traumatic origin, and oplastic affections, the antiseptic method can be applied with almost as much lvantage as in the category of orthopædic resections. In cases, however, of ronic inflammatory lesion with suppuration, the presence of numerous fistulæ, d the formation of fungoid tissue within the joint and along the fistulous tracks, e case is different, and the surgeon cannot obtain complete immediate reunion ter resection, and has, during the after-treatment, to deal always with more or ss abundant suppuration. Still, in such cases, this suppuration is considerably minished by carbolized dressings, and in all kinds of traumatic and pathological sections, antiseptic methods, according to M. Ollier, are imperiously demanded. The antiseptic method, whilst it has extended the range of operative surgery in e region of articular and osseous lesions, has contracted its application in an-her. As this method prevents suppuration after an orthopædic or a primary aumatic resection, so also will it act after an accidental wound into a joint with acture of the articular extremities of the long bones, and thus prevent the com-lication which alone indicates resection in many of such cases. In many trau-atic lesions of this kind, antiseptic cleansing of the wound, and the removal of etached splinters will, it is stated, suffice for the preservation of the limb; and

in others, a more or less extensive removal of fragments will replace a true resection. Thus the antiseptic treatment has reduced very much the number of primary traumatic resections, and especially those resections called by M. Ollier preventive, because they have been practised with the view of preventing the dangers to which formerly the subject of a contused wound of a large joint was always exposed.

During six months of the last year, M. Ollier, applying exclusively Lister's method of antiseptic dressing, performed seventeen resections of large joints, one resection of a pseudarthrosis, and two operations for osteotomy. In all these cases, the patients, so far as concerned the immediate result of the operative treatment, recovered without the occurrence of any infectious complications. M. Ollier, deprecating any desire to exaggerate the merits of Lister's antiseptic method, states that, in comparing this series of cases with those previously observed by him, he is compelled to recognize the fact that in the Hôtel-Dieu of Lyons he has never had a series so invariably satisfactory, with regard both to the simplicity of the processes of cicatrization and to the final result. Through comparison of a series of cases of any operation treated with Lister's dressing with analogous series of cases treated by other antiseptic methods, M. Ollier has been led to give the preference to the former. During the last four years he has performed resection of the elbow in thirty-two cases, in all of which the patients recovered. In nine only of these cases was Lister's dressing applied. In some the wound was uncovered; in some it was treated according to a plan of so-called immovable antiseptic occlusion, and in others by an imperfect dressing of carbolic acid. But though these different methods had all the same result with regard to the preservation of life, they varied with regard to complications. Whilst in the nine cases treated strictly according to Lister's method, no serious complication was observed, in many of the other cases the cicatrizing process was interrupted. In five of these last cases erysipelas occurred, and in two local gangrene. From his own experience of Lister's dressing in cases of resection, M. Ollier has made out that this prevents inflammation of wounds without arresting the physiological processes of repair. The cicatrization and repair of osseous structure progress equally with the reunion of skin, and are not affected by the antiseptic treatment. Indeed, the organization of bone, and the ossification of the periosteal sheath, are rather accelerated than retarded by this plan of dressing, since this protects the wound and the internal layer of granulation-tissue from danger of infection. In every case of resection treated according to Lister's method, whether the operation be practised for deformity, injury, or chronic disease, M. Ollier endeavours to establish free drainage by a multiplicity of tubes, and refrains from applying sutures along the whole extent of the wound. In cases of chronic joint-disease, where the synovial membrane is much thickened and vascular throughout, the superficial portion is excised or scraped away, and the deeper portions destroyed by the actual cautery or some chemical agent (chloride of zinc, nitrate of silver, perchloride of iron). Thorough ablation of this thickened granular layer is not practised by M. Ollier in every case. Though it may be right to attack with the curette all tuberculous fungosities, and whatever tissue resembles such structures, it should not be forgotten that the exuberant fungous growths about fistulous tracts either waste or become further organized, after, through the extraction of a sequestrum or some other dead material, the source of the suppuration has been removed. The thick granular layer of a diseased joint, when the result of simple inflammation, is useful, M. Ollier thinks, after it has been altered, in the repair of the bones and the articular structures, and, therefore, ought not to be wholly removed. A portion only should be cut or scraped away, or the surface should be touched by the actual cautery, which is regarded as an excellent agent for con-

verting a fungous into a plastic process. The subsequent suppuration on this part of the wound will, it is stated, be of no consequence so long as the superficial structures and the edges of the wound do not become inflamed, and so long as fever and symptoms of septic absorption are absent. Lister's antiseptic method is of great value, M. Ollier holds, when applied in cases of subperitoneal resection. By preventing inflammation, this method guards against destruction of the osteogenetic elements attached to the inner surface of the periosteum, and arrests any diffuse suppuration which, besides the accidents common to all resections, would prove a positive obstacle to the accomplishment of the processes of repair. In almost all cases of resection, Lister's method is valuable, not only in guarding the patient against dangerous septic affections, but also, as it accelerates the healing of wounds, in its enabling the surgeon to arrest, after the operation, those changes in muscular and nervous tissue which are the result of prolonged suppuration, associated with prolonged immobility of the limb. The application of Lister's method, in cases of severe open wound of a bone or joint, should, in M. Ollier's opinion, lead to a difference in the treatment of such injuries. In case of wounded joint with fracture, instead of resorting to a resection, that is to say, to an operation consisting in the removal of all free fragments, and in bringing together the ends of the remaining portions of the injured bones, the surgeon might rest content in freeing the wound of foreign bodies and loose fragments of bone, leaving in place the fragments that are still covered by periosteum, and even such as have been partially denuded. It is not the injury itself, M. Ollier points out, that causes the death of such fragments, but the inflammation and suppuration following such injury. Such fragments, as is well known, in cases of simple fracture usually unite with the rest of the injured bone.

A case of partial resection of the tibio-tarsal joint is reported, to show the good results of Listerism in operations for the partial removal only of one or both opposed surfaces of bone forming an articulation.

In conclusion, M. Ollier protests against an unnecessary and too widely extended application of operative surgery with antiseptic precautions to deformities of the skeleton and its articulations, which have hitherto been regarded as amenable to ordinary orthopædic treatment.—*Lond. Med. Record*, April 15, 1881.

Midwifery and Gynæcology.

A Case of Extra-Uterine associated with Intra-Uterine Fœtation, in which Abdominal Section was performed.

Dr. GALABIN related, at a recent meeting of the Obstetrical Society of London (*Med. Times and Gazette*, May 28, 1881), a case of extra-uterine associated with intra-uterine fœtation, in which abdominal section was performed. The patient, who was thirty-six years old, was married in the spring of 1878. In the summer of that year she had an abortion, and in April, 1879, was delivered, with the assistance of forceps, of a full-term child. She expected her second confinement in September, 1880, and engaged Mr. Thomas Duke, of Rugby, to attend her. During the fourth and fifth months of pregnancy she had considerable pain and tenderness in the right side of the abdomen. Two tumours were then discovered. That on the left side gave the usual evidences of fœtal life, and was clearly the pregnant uterus. Over the tumour on the right side nothing could be heard by auscultation; and Mr. Duke, as well as several other medical men who examined the patient, concluded that the case was probably one of an ovarian tumour com-

plicating pregnancy. On June 16, symptoms of rupture suddenly occurred, followed by those of peritonitis, and the outline of the right-hand tumour was found to have disappeared. The patient's state having become very critical, the author was sent for, and reached Rugby on the evening of the 19th. He was inclined, from the history, to agree with the diagnosis of ruptured ovarian cyst, but the possibility of combined extra- and intra-uterine fœtation existing was entertained. He suggested an exploratory operation as the only chance for life, and performed this on the morning of the 20th. A large quantity of blood and clot was found in the peritoneal cavity, and an extra-uterine fœtus contained only in its thin membranes. The placenta, attached to the back of the pregnant uterus and the posterior surface of the right broad ligament, was left *in situ*, and a drainage-tube placed in the wound, entering the general peritoneal cavity. The operation was performed under carbolic spray. The patient appeared to be doing well for the first two days, and the temperature never rose above 99.8°. On the morning of the 22d, however, labour came on, and a child, which presented by the breech, was delivered stillborn. Though there was very little hemorrhage by the vagina, a great deal occurred through the drainage-tube. On the 23d the temperature was normal, but hemorrhage still went on through the drainage-tube, and she died, apparently from loss of blood, on the 24th. The author attributed the secondary hemorrhage to the shrinking of the uterus in the expulsion of the fœtus, and consequent further detachment of the extra-uterine placenta from its posterior wall. Both fœtuses appeared to be of about six and a half months' development, but the extra-uterine fœtus weighed only one pound and a half, the intra-uterine two pounds and three-quarters. A review was appended of similar recorded cases; in all of which the extra-uterine pregnancy appeared to have been of the abdominal form, while in none of them was a complete diagnosis made while both fœtuses remained within the abdomen.

Dr. ROUTH congratulated the author on his skill and power of diagnosis. It appeared that death was due to the further detachment of the placenta in labour, and he suggested that it would have been expedient to reopen the abdomen, and arrest hemorrhage by the actual cautery. He had seen adhesions in ovariotomy, even adhesions to the liver, successfully treated by the actual cautery.

Dr. DUNCAN regarded uncontrollable hemorrhage as the great difficulty in surgical interference with extra-uterine pregnancy, and this even many months after the death of the fœtus. He did not look with much hope on the actual cautery as a means of arresting this or any other kind of hemorrhage, as he had used it, and seen it used, in vain.

Dr. GALABIN said that, on account of the distance of the patient, he had not had the opportunity of deciding on the expediency of reopening the abdomen. He thought that a styptic, such as perchloride of iron, would be more effectual than the actual cautery in arresting hemorrhage in such a case.

—

Phlegmasia Dolens with Lymphatic Varix.

Dr. MATTHEWS DUNCAN, at a late meeting of the Obstetrical Society of London (*Med. Times and Gaz.*, May 28, 1881), read a paper on a case of phlegmasia dolens with lymphatic varix. The author was disposed to support the view of Tilbury Fox and others, that phlegmasia dolens is due to venous and lymphatic inflammation and obstruction, and that of these two the lymphatic disease is the more important, especially as being probably present in every case, while the venous disease is occasionally absent. The case of white-leg occurred in the downward progress of a characteristic case of cancer of the womb. During its presence there appeared lymphangiectasis of a part of the skin of the thigh, and

is disappeared as the phlegmasia disappeared. The part visibly affected was the upper and outer part of the anterior surface of the left thigh, and constituted an oval or triangular area, broader above than below, and of such extent as might be nearly covered by the hand. There was no pain or tenderness. The projecting vessels, covered by epidermis having a yellowish-white tint and pearly lustre, were seen and felt, and the prick of the small point of a knife allowed a large drop of limpid lymph to immediately exude. A similar affection of lymphatics occurred during a slight attack of phlegmasia in the right limb, which began as the disease was slowly disappearing from the left. The lymphangiectasis occurred in an area of skin mechanically weakened by being the seat of closely set spindle-shaped ribbon-like skin-cracks. These cracks were obscured by the lymphatic distension, and did not subsequently become again visible as skin-cracks, except in small parts. The lymphangiectasis was probably the result of general lymphatic tension in the whole limb, the special varicose lymphatics becoming so in consequence of being imperfectly supported by the weakened cracked skin. Similar phenomena were observed in the abdominal skin-cracks of pregnancy, under circumstances not regarded as morbid.

Dr. PLAYFAIR said that many clinical facts proved that thrombosis of the veins was not of itself sufficient to account for the phenomena of the disease. Thus, there were cases of thrombosis of the veins of the lower extremities, occurring in gouty subjects, in connection with which nothing like phlegmasia dolens was observed. Dr. Duncan's cases showed the probably intimate relation between a certain amount of septic absorption and phlegmasia, which was not uncommon in connection with cancer of the uterus. He did not think that there was ground for assuming that lymphatic obstruction had more to do with phlegmasia than venous obstruction. He had never seen any lymphangiectasis in puerperal cases, and in some instances thrombosis of pulmonary arteries preceded the phlegmasia.

Dr. GRAILY HEWITT thought that there was no doubt that in typical cases of this disease both lymphatics and veins were affected. It was known that the venous obstruction originated in coagulation in the uterine sinuses extending to the iliac trunk, and it was probable that the lymphatic thrombosis occurred in a similar way.

Dr. DUNCAN would not attempt to estimate precisely the comparative influence in phlegmasia of venous and of lymphatic obstruction. He would only say that while sometimes venous obstruction was certainly absent, we could not say the same of lymphatic obstruction.

Aphthous Vulvitis and Gangrene of the Vulva in Children.

Dr. PARROT contributes to the March number of the *Rev. de Méd.* an exhaustive treatise on aphthous vulvitis in infants, founded upon an experience derived from 56 cases. Premising that the disease, even under this name, was known to Hippocrates, he proceeds to describe the result of his own observations. Whilst the vulva, especially the labia majora, and less often the labia minora and clitoris, are the constant seat of the disease, it is not necessarily limited to them, but often extends to neighbouring parts, such as the perineum, margin of the anus, the genito-crural folds, and groins, in different degrees of frequency, in the order enumerated. The appearance of the disease varies at different stages. At the onset, it consists of small rounded or semi-spheroidal elevations of the epidermis, pale, or grayish-white, often depressed in their centre, and with a diameter of 1 to 4 millimetres, and closely resembling buccal aphthous patches. The surrounding integument is usually but slightly affected, though sometimes red, and slightly swollen. They vary in number from six to fifteen, isolated or in

groups, sometimes confluent. This condition lasts from thirty-six hours to three days, and is followed by the second stage, which is marked by ulcers with a gray or yellowish base, surrounded by a red zone, and accompanied by pruritus, which is often severe, and necessitates the employment of some means of restraint from scratching. When the ulceration extends, its edges are raised, and the neighbouring parts much swollen, and of a bright red, especially the labia minora and clitoris. This ulcerative stage constitutes the acme of the disease, whatever its subsequent course, and doubtless, Dr. Parrot observes, may be recovered from without treatment in healthy subjects; though, since all his cases were subjected to systematic treatment, with the result of rapid improvement, he cannot assert this to be the case. Under unfavourable conditions, the ulceration gives place to gangrene, which is not to be regarded, properly speaking, as a complication of aphthous vulvitis, but rather a modification or one of the forms of the disease, which manifests itself under as yet little known conditions. The gangrene may spread to an enormous extent, involving the perineum, rectum, and integuments around the coccyx, large moist eschars sloughing away, leaving deep excavations. Even from such extensive destruction, recovery may take place with remarkable completeness of restoration, the reparative process seeming to vie with the destructive.

The extent to which the system is affected by the local affection, whilst in the aphthous and ulcerative stages, is but slight, and is involved in the general febrile state (measles, etc.) to which the disease is secondary. With the existence of gangrene, the usual severe constitutional symptoms set in, and may be fatal. In those cases which do not proceed to gangrene it is noticeable that the ulcers which spread over the perineum and the rectal mucous membrane extend more rapidly and last longer than those in other regions, probably because of their liability to disturbance and irritation by the excretions. Careful examination of these parts is, therefore, necessary before pronouncing that a cure is effected. It is a remarkable circumstance that enlargement of the lymphatic glands does not occur, or only to the slightest extent. The diagnosis of aphthous vulvitis is easy. The infecting chancre has its own characteristics, and affects the lymphatic glands. The vulvitis, which is often associated with variola and varicella, is indistinguishable from the aphthous form, but the eruption of these diseases reveals the nature of the case. Among the more interesting points in connection with the etiology of the disease are: 1. The age, the majority of the cases occurring from the second to the fourth year, the youngest of the 56 children being twenty months old, and the eldest 7½ years. 2. The influence exercised by other maladies. Of the 56, there were associated with measles, 39; with whooping-cough, 4; with varicella, erysipelas, pneumonia, and diphtheria, 1 each; and 9 independently of any other disease. The marked frequency of measles compels us to assume some intimate relation between these two states. What this is, the author confesses himself ignorant of; but he points out that measles leads in many cases to an ulceration of the antero-external surfaces of the arytenoid cartilages, though not of an aphthous character. All the cases of gangrene were observed in children the subjects of measles, which may be explained by a tendency of the febrile blood to form thrombi in the pudendal vessels.

It is difficult to state the duration of the disease, but the most intractable ulcers yielded to treatment within eight days. Dr. Parrot does not hesitate to give a favourable prognosis in all cases, recovery from the local affection taking place even when the primary disease may be fatal. The treatment adopted by the author since 1873, whatever the stage of the disease, is to cover all the affected

rea with a uniform layer of iodoform, and over that a covering of lint. One pplication will often effect a cure, and rarely more than three are necessary, at ntervals of twenty-four hours, preceded by careful washing of the parts. This reatment is sedative rather than painful, and since it has been pursued, cases of angrene, which, under the old methods of poultices, charcoal powders, alcoholic pplications, chlorate of potash, nitrate of silver, etc., were frequent, are now unnown.—*London Med. Record*, May 15, 1881.

—

Ovariotomy and Pregnancy.

The following three cases are related by Dr. J. PIPPINGSKÖLD in the *Finska äkaresällsk. Handlingar*, Band xxii.:—

CASE I. A L. M., aged 41, menstruated first at the age of 15, and was arried at 18. She had had ten labours, the last two and a half years nce. A tumour was first observed in March, 1877; the menses had become regular, and ceased in July, 1878. She was admitted to hospital at the end of anuary, 1879. Three days later, twelve and a half litres of ropy colloid mateal were removed by tapping. On the last day of February dyspnœa had inreased, and pains resembling those of labour had set in; she was now again pped, but only two and two-third litres of watery fluid escaped. As she had vere orthopnœa, and became worse during the next two days, ovariotomy was erformed. As soon as a large portion of the contents of the cyst had been moved, she was found to be pregnant; the possibility of this had been borne mind before the operation. The pedicle was cauterized, and secured by eleven gatures. Immediately after the operation, the labour-pains, which had probay commenced during the previous night, became more powerful; seven hours ter, the liquor amnii escaped, and a dead child was soon afterwards born. Dr. ppingsköld attributes the death of the fœtus to extravasation into the placenta, d believes that it might have been born alive if the operation had been perrmed fourteen days earlier.

CASE II. L. S., aged 34, married six years, had two living children (the oungest three years old), had miscarried at the sixth month with twins two ears before her admission to hospital in July, 1877. The catamenia, which had een normal, had disappeared three months previously. The abdomen had adually enlarged after the miscarriage. The diagnosis of an ovarian cystic mour on the left side was made. Ovariotomy was performed on July 27; on e eleventh day the patient left her bed, and returned home a few weeks afterards. She was delivered of a fine girl on November 3.

CASE III. In the beginning of April, 1878, Mrs. A. was sent to Dr. Pippingöld by another medical practitioner, who had diagnosed an ovarian cyst in ombination with ascites. The patient was 24 years of age; she had been mared three and a half years, and had had two children, the youngest being one d a half years old. After her last confinement, her abdomen began to enlarge, d was, when Dr. Pippingsköld first saw her, greatly distended; she had also olapse of the uterus. A preliminary tapping was performed; after which an bdominal bandage was applied for twelve weeks, with a glycerine tampon, comess, and T-bandage to the uterus. On June 23, ovariotomy was performed; e cyst was found to be connected with the right ovary. On the left ovary ere three small cysts with clear serous contents, which were opened and cauterzed. The patient was kept in bed five weeks, during which a glycerine tampon as daily introduced into the vagina. She menstruated normally in July. After e had left her bed, the uterus was found to be in its normal position, and re-

mained so. On October 28, 1879, she was delivered of a child weighing more than ten and a half pounds, and made a good recovery.—*London Med. Record*, May 15, 1881.

—

Removal of Uterine Appendages for the Arrest of Uterine Hemorrhages.

At a late meeting of the Royal Medical and Chirurgical Society (*Lancet*, May 28, 1881), Mr. LAWSON TAIT read a paper on this subject. He referred to the use of the statistical method in testing the real value of operations, and especially instanced ovariotomy as one which would not have obtained the complete acceptance it has received had not the careful statistical method of Mr. Spencer Wells shown that its results could be favourably compared with those of every other major operation in surgery. Mr. Lawson Tait wished to lay his experience before the Society, in order to obtain its decision as a guide for the future for himself and others. After protracted trials of drugs for the arrest of uterine hemorrhage, he had come to the conclusion that all were absolutely without effect save ergot and two salts of potash, the chlorate and the bromide, and these were by no means uniformly successful in giving permanent relief. In all the cases he had to relate these drugs had been fully tried before the question of operating was discussed. He had entitled his paper "The Removal of the Uterine Appendages," because his experience seemed to show that the removal of the ovaries was not a certain method of arresting menstruation, while removal of the tubes as well seemed to be so.

The author then related thirty-one cases, of which four were fatal, twenty-seven recovering from the operation. A summary table was appended to the paper which was a complete list of the operations and results.

The author summed up with the following conclusions, which he considered might be legitimately drawn from them. 1. That, so far as its primary results are concerned, removal of the uterine appendages for the arrest of intractable uterine hemorrhage is an operation which is quite as easily justified as any of the major operations of surgery. 2. That so far as its secondary results are yet known it is an operation which yields abundant encouragement for its further trial; as conclusions which are indicated but not wholly proved, he thought he might formulate a statement that removal of the ovaries alone is not sufficient to arrest menstruation but that removal of both tubes and ovaries does at once arrest it. So far as some of these cases have gone the arrest would seem to be permanent. This conclusion is quite in harmony with what is known of removal of both ovaries for large cystomata, for in such cases the tubes are almost uniformly included in the clamp or ligature. Three at least of the cases, and probably two others, show that the arrest of menstruation by this means leads or may lead to the atrophy of uterine myoma. Finally, there is some close connection, here pointed out, he believed for the first time, and worthy of very close study, between uterine myoma and its accompanying hemorrhages and cystic disease of the ovaries. In two of the cases cystic disease seemed to be the cause of the hemorrhage without any myoma intervening. One other conclusion, he thought, was justified, that the whole subject is worthy of careful study, and should not be made the subject of premature and hostile conclusions.

MEDICAL NEWS.

Not a failure of Vaccination as a Prophylactic.

It can scarcely be doubted that the surest way to overcome the assailants of our great safeguard against variola is to determine with absolute accuracy the limits of its protective power, in order that we may not enthusiastically claim too much for Jenner's beneficent discovery. Hence a careful consideration of circumstances attending the recent complete destruction of a band of Esquimaux in France by smallpox is especially important at the present time, when vaccination is being so violently attacked by many ignorant or prejudiced enemies. From the official report of Dr. Leon Colin (Professor d'Epidémiologie du Val de Grâce), made after a thorough investigation of the whole subject, we learn that a party of eight Esquimaux brought from their native Labrador (probably to take part in some kind of exhibition or theatrical performance) disembarked at Hamburg the 26th of September, 1880, and visited in succession Berlin, Prague, and Frankfort, arriving at Darmstadt on the 13th of December, stopping at Crefeld, a small town of Rhenish Prussia, from the 18th to the 30th of that month, and reaching Paris, where they were taken to the Jardin d'Acclimation, on the last day of the year. On the 14th of September, just two weeks after leaving Prague, where an epidemic of variola was raging, a young girl of the troupe died of smallpox, the eruption being fairly apparent. At Crefeld, thirteen days afterward, the wife of one of the party died with the symptoms of hemorrhagic smallpox, but without any eruption being visible, and on the 31st of December, at the same place, another young girl died, exhibiting the characteristic eruption.

On the 1st of January, the day after their arrival, the remaining five Esquimaux were carefully vaccinated with animal vaccine virus, which had been preserved in tubes, and five days later the operation was repeated, in both instances, however, unfortunately without effect. This failure is attributed by Dr. Colin to the fact that, the systems of the Esquimaux being already infected with the variolous poison, they were all on both occasions in that stage of incubation of smallpox in which want of success in vaccination is (he states) the rule. It seems strange that, in view of the great previous mortality among the troupe, arm to arm vaccination was not daily practised, and varied, indeed, to different parts of the body, in order to give these unhappy exiles a chance of deliverance from the terrible disease which proved fatal to them all before the middle of January. And yet it is obvious that the time when the prophylactic should have been applied was when they first landed in Hamburg, or certainly at Prague, which was known to be the seat of an epidemic, or at any rate at Darmstadt, when

the death of a first victim, marked with the characteristic eruption, gave a primary signal of the terrible danger to which the whole band was exposed. But since the precaution was not thus resorted to *in time*, it is equally manifest that there is no proof that the failure of vaccination to protect these unfortunates from smallpox was due to aught but a neglect of the proper method of its timely application, or in any sense owing to a deficiency in its prophylactic power.

The fact that all of the patients in this lamentable series of cases died after a few days' illness, and two of them without showing any eruption, suggested to some medical men in Paris that variola was here so modified by racial peculiarities, or other causes, as to be less amenable to the influence of vaccination. But if we investigate the course of smallpox in nations among whom it has not previously been prevalent, and where consequently there is, so to speak, a new field opened to its ravages, we will find that it has often in the past history of mankind manifested the same virulence and fatality. The circumstance also that no epidemic of variola seems to have been originated by these Esquimaux, strongly indicates that for their associates and caretakers, a certain amount of *inherited* insusceptibility (which probably exists in the inhabitants of countries, where smallpox frequently occurs, and weeds out, as it were, the families which are most easily affected by its poison) combined with the *acquired* protective influence of vaccinia to preserve them from its deadly power. All the employés of the Garden of Acclimation were re-vaccinated with human vaccine lymph taken from the arm of an infant on the eighth day, the apartments occupied by the Esquimaux were disinfected with sulphurous acid, and their effects either burned, or purified by prolonged exposure to boiling or to dry heat of high degree. The Parisian Council of Health in seeking to profit by this remarkable example, urges upon the proper authorities, the prompt vaccination immediately upon landing of all foreigners arriving at French ports, from countries such as Labrador, where neither prevalent variola nor vaccine disease has tested their susceptibility to smallpox. This wise precaution might well be adopted here in America in regard to the arriving emigrants, annually crowding to our shores from regions where systematic vaccination and re-vaccination are neglected, especially as the health reports of our western States record numerous local epidemics, the germs for which have been imported by Scandinavian and other settlers. Furthermore, the Council earnestly advocates the missionary work of introduction as rapidly as possible of the process of vaccination among the various nations to whom it is comparatively unknown; pointing out that the operation would not only preserve a few individuals from the perils of variola attending a voyage to Europe, but would protect whole populations from danger by the germs of smallpox imported by sailors or travellers, to which they are continually more or less exposed without its aid.

Infected Meat.

A short time since we called the attention of our readers to the danger of tuberculosis being transmitted by the ingestion of diseased meat, and the recent panic on the continent of Europe in regard to trichinosis in pork indicates that a knowledge of the exact extent of other dangers from infected animal food can scarcely be too often or too earnestly urged upon the community at large. Strenuous efforts, evidently inspired by the immense pecuniary interest involved, have been made to allay popular anxiety on this point, and a late account states that, among four hundred hogs examined at random in Chicago, no trace of Trichina was discovered. Investigations, which we may readily suppose were less partial, and, therefore, more searching, place the number of American hogs infected with trichina at four per cent., and when we consider that a large proportion of the cats and rats in cities contain trichina, and are occasionally eaten by swine, we comprehend at once why the wise old Hebrew lawgiver forbade pork to his followers. The obvious reason for our comparative immunity in this country from epidemics of trichinosis is found in our habit of *thoroughly cooking* all animal food, a culinary precaution which is infallible, and should never be omitted. Any one interested in this subject may consult with profit Dr. Noah Cressy's address on "Diseased Meat and its Consequences upon our Health and Happiness," published at Hartford, Conn., last year.

The American Laryngological Association.—The third annual congress of this association convened in Philadelphia, on May 9, 1881, and continued until May 11th, holding morning and afternoon sessions. The meeting was held in the hall of the College of Physicians, the use of which had been tendered by the College to the Association. A full attendance of the Fellows was present, and a number of candidates were elected. The meeting was presided over by Dr. J. Solis Cohen, and the papers presented were of great interest, and, as a rule, practical in their character; the discussions were spirited. Entertainments were tendered the Association by the President; and by the Philadelphia Laryngological Association. An excursion to Atlantic City on the afternoon of the last day included the exercises of the meeting, which was considered the most successful that has yet been held by the Association.

First Day's Proceedings.—The President, Dr. J. Solis Cohen, opened the session, at 10.30 A. M., on Monday, May 9th. Dr. Harrison Allen made a brief address of welcome, and the President then read his annual address.

The reading of papers being next in order, Dr. Frederick J. Knight, of Boston, read a clinical paper on Lupus Laryngis, followed by one on Lupus of the Pharynx and Larynx, by Dr. Morris J. Asch, of New York, which led to considerable discussion, in which a remarkable variety of opinions were upheld regarding the pathology of Lupus.

Dr. Andrew H. Smith, of New York, read a communication on Certain Neuroses of the Throat, in which laryngeal disorder was shown to exist in some cases as the result of reflex irritation, frequently uterine in its origin.

In the afternoon, papers were read by Dr. Beverley Robinson, of New York,

on the Laryngeal Affections of Pulmonary Phthisis; by Dr. Wm. Porter, of St. Louis, on the Prognosis of Laryngeal Phthisis, and by Dr. F. H. Bosworth, of New York, on Tubercular Ulceration of the Mouth, with a report of Cases. In their essays, and in the discussion following them, a more hopeful view of the prognosis of laryngeal phthisis was given than is generally stated; the treatment being largely local by means of medicated sprays.

Second Day.—A business meeting was held from 10 to 11 o'clock, at which candidates were balloted for, and other private business transacted; reports of the Treasurer, of the Committee on Nomenclature, and of the Publication Committee were received and approved. The following were elected to active membership: Drs. D. Bryson Delavan, of New York; Urban G. Hitchcock, of New York; George W. Major, of Montreal; Ethelbert C. Morgan, of Washington; Herman Mynter, of Buffalo, and J. W. Robinson, of Detroit.

In regard to the following question, referred by the Council to the Association for their decision: Shall the inaugural theses of candidates for Fellowship be published as a part of the transactions of the Association in the Annual Volume? it was decided that it should be left to the discretion of the Council at each annual meeting.

Dr. Louis Elsberg, of New York, read a Contribution to the Histology of the Thyroid Cartilage, in which recent views on the structure of so-called hyaline cartilage structure were discussed, and the bio-plasmic character of the inter-cellular material maintained. He also exhibited an improved apparatus, by which the calcium light was made available for office use for laryngoscopic examinations, and, secondly, Trouvé's Galvanic Accumulator for illumination and cautery purposes. The President said that he had tried it as a means of illumination and for actual cautery, but it had not been satisfactory in his hands.

Dr. Wm. C. Glasgow, of St. Louis, read a paper On the Operation for Deviation of the Nasal Septum, in which Steele's method of cutting the cartilage by radiating incisions and restoring its position by pressure was advocated. The paper was freely discussed, this operation not being sanctioned by the Society generally.

An interesting essay, by Dr. Carl Seiler, upon the Effect of the Condition of the Nasal Cavities upon Articulate Speech, was listened to with marked attention, as it discussed the physical conditions of articulation and the functions of the upper air-passages in speech.

By permission, Dr. J. O. Roe, of Rochester, reported a curious case of Laryngeal Whistling; Dr. Glasgow also read a volunteer paper, containing the notes of a case of paralysis of the abductor muscles of the larynx.

Dr. Clinton Wagner read a paper On Sub-Hyoidean Pharyngotomy for the Removal of the Epiglottis, with an illustrative case; in which the advantages of the horizontal wound were discussed, and its enlargement by an antero-posterior incision recommended (a T incision) in difficult cases.

The question of Hemorrhage after Tonsillotomy was discussed by Dr. Geo. M. Lefferts, of New York, and the danger of serious bleeding pointed out, due, in the author's opinion, to section of the enlarged branches of the ascending pharyngeal arteries of the external carotid, rather than to the trunk of the interna carotid, as is usually stated by writers. In the free discussion which followed, the comparative advantages of the guillotine, the bistoury, the galvano-cautery, and the destruction by caustic applications, each found advocates.

A paper, by Dr. C. E. Sajous, on Paralysis of the Vocal Cords due to lead-poisoning, was read by title.

Third Day.—Dr. Wm. C. Jarvis read a paper on Chronic Irritative Hyperæmia of the Larynx, which was favourably discussed by Drs. Elsberg, Shurley,

A. H. Smith, Seiler, Cohen, and Bosworth. Dr. Jarvis also exhibited an ingenious instrument for removing hypertrophied tissue from the inferior turbinated bone.

Dr. J. O. Roe read a paper on the Comparative Value of Atomized Fluids in the Treatment of Diseases of the Larynx, which advocated this method of medication.

Dr. Delavan, of New York, by permission, also exhibited an instrument, which was an inverted Säss's tube for throwing an upward spray into the pharynx, and which was considered by several fellows as a decided improvement.

Dr. Wm. H. Daly concluded the public exercises by reading a communication upon the Relations of Hay Asthma and Nasal Catarrh, and the Congress went into executive session.

On motion of Dr. Knight, it was resolved that fellows who take no active interest, either by paper or presence, in the sessions of the Congress for a period of three years, may, unless proper and satisfactory excuse to the Council be made, be dropped from the roll.

A communication was received from the editor of the *Archives of Laryngology*. On motion, the whole subject of publication of proceedings was referred to the Council with power.

The following fellows were elected Delegates to the Subsection on Laryngology of the International Medical Congress of 1881: Drs. Cohen, Lefferts, Lincoln, and Bosworth.

On recommendation of the Council, Dr. Morell Mackenzie, of London, was elected an honorary fellow, and Drs. M. Krishaber, Paris, L. Mandel, Paris, Karl Stoerck, Vienna, Leopold Schrötter, Vienna, Felix Semon, London, and R. Voltolini, Breslau, were elected corresponding fellows.

The following officers were duly elected for the succeeding year: *President*, Dr. F. J. Knight, of Boston. *Vice-Presidents*, Drs E. L. Shurley, of Detroit; Wm. Porter, of St. Louis. *Member of Council*, Dr. Harrison Allen, of Phila.

Next place of meeting, Niagara Falls, N. Y., during the month of June, the exact date to be decided by the Council, so that it shall not interfere with the meeting of the American Medical Association.

After the customary votes of thanks, the Association adjourned.

—

The Pennsylvania State Medical Society.—The thirty-second annual meeting of the State Medical Society was held at Lancaster, Penna., on May 11th, 12th, and 13th, 1881. It was the largest meeting of this Society that has ever been held, nearly three hundred members signing the register. The session was harmonious, and the proceedings were enlivened by many interesting papers and appreciative discussions.

The formal opening of the meeting by prayer was followed by an Address of Welcome from Dr. Henry Carpenter, of Lancaster.

Dr. Allis offered a resolution that the Philadelphia County Medical Society be made custodian of the publication of the Proceedings of the Pennsylvania State Medical Society and of the Transactions of such other State medical societies as shall exchange with it, until the Pennsylvania State Medical Society shall make other provisions for the same, and that the Publishing Committee shall be a Library Committee to report to next meeting of this Society. Adopted.

Dr. Sutton offered the following, which lies over under the rule:—

Section 2, Article III., of the Constitution shall be so amended as to read as follows:—

Every member of a county medical society in Pennsylvania shall, so long as he

is in good standing, be a member of the State Medical Society and a delegate to its annual sessions.

In the afternoon, Dr. Albert H. Smith, of Philadelphia, offered a resolution in regard to giving the control of female insane patients in hospitals exclusively to women, and calling upon the Legislature to recognize this principle in making its appointments for the hospital at Warren, as had been done elsewhere in the State. After some discussion it was made the special order for the succeeding day.

Dr. S. M. Ross, of Blair Co., read the Address in Surgery, and several other papers were read, including one by Dr. S. D. Risley upon Diseases of the Lachrymal Passages, and one on the Pathology of Shock, by Dr. C. C. Seabrook, in which the phenomena are declared to be due to a paralyzing effect upon the vasomotor centre in the medulla oblongata.

The President's Annual Address, by Dr. John T. Carpenter, of Schuylkill Co., was mainly devoted to the discussion of the management of the insane. He pointed out the defective system of treatment prevailing in many asylums in the United States, and urged the adoption of some comprehensive system of superintendence of all the insane hospitals, with a view of securing an approach to uniformity in classification and administration.

A complimentary musical entertainment was given to the delegates, at the close of the President's Address, at Fulton Hall, which was well attended.

Second day.—After the appointment of the Nominating Committee, the resolution of Dr. Smith came up for action, and after considerable discussion the motion was lost. Several other amendments were adopted.

The amendment to the Constitution offered by Dr. Carpenter last year, allowing representation of the College of Physicians of Philadelphia, also failed to be adopted.

Dr. S. S. Schultz, of Danville, read a very interesting Report on Mental Disorders, in which the want of sufficient accommodation for the insane in our public institutions was pointed out, the number of the insane in our constantly growing population being steadily on the increase; he estimated the number of insane poor in this commonwealth at nearly 6000.

In a volunteer paper, Dr. John Curwen, of Dauphin Co., insisted upon the value of rest and careful attention to nutrition as restorative agents in nervous disease.

This was followed by an interesting communication from Dr. Traill Green, of Easton, entitled "The State Medical Society and the Preparatory Education of Medical Students," in which great stress was laid upon the necessity of proper preliminary studies for medical students.

Dr. O. H. Allis also read a paper upon the same question, "In what should Preliminary Examinations consist, and what step should be taken to make them uniform throughout the State?"

Dr. W. M. Findlay, of Blair Co., offered the following, which was adopted:—

Resolved, That a committee be appointed to prepare a schedule of subjects on which applicants for permission to study medicine shall be examined by the Board of Examiners of county societies.

The President appointed on this committee to report at the next meeting, Drs O. H. Allis, Traill Green, W. R. Findlay, John B. Roberts, and W. B. Ulrich.

At the afternoon session, Dr. Wm. Goodell read a paper on "The Extirpation of the Ovaries for Insanity," in which some illustrative cases were reported showing the value of this procedure in certain cases; the author noticing the strong hereditary tendency of mental disease, advocated the trial of this operation, which possessed the incidental advantage of preventing the propagation of insanity.

Dr. J. Aug. Uhler, Chairman of Committee on Nominations, made the follow-
g report: *President*, Jacob L. Ziegler, of Mount Joy. *Vice-Presidents*, 1.
s. A. Reed, of Allegheny; 2. W. L. Roland, of York; 3. J. W. Houston, of
nester; 4. W. Murray Weidman, of Berks. *Place of Meeting*, Titusville, Craw-
rd County, on second Wednesday of May, 1882. Adopted.

A Report on the State Board of Health was presented by the Permanent
ecretary.

On motion John Norris, Esq., of the *Philadelphia Record* was allowed to ad-
ess the association upon the progress of the bill to create a State Board of
ealth. A vote of thanks was subsequently tendered the *Record* for its services
aid of medical legislation and medical reform. Dr. R. L. Sibbett, of Carlisle,
esented a report on Medical Legislation, which was adopted. A resolution was
ssed indorsing the bill then before the State Legislature for creating a State
ard of Health, and regulating the practice of medicine.

Dr. Benjamin Lee, of Philadelphia, read the Annual Address on Hygiene, in
ich he discussed certain matters connected with the purity of the atmosphere,
ecially in large cities, calling especial attention to the dangers of inhaling
eet-dust, and of breathing sewer-gas in the houses; and recommending a mer-
y valve for water-closets.

Dr. R. G. Curtin, of Philadelphia, read a paper on Catarrhal Inflammation of
e Pancreas, a heretofore undescribed Disease. The principal symptoms were
rrhœa, with fatty stools, followed by dyspepsia, and later symptoms of anæmia
d starvation, to be treated in the early stages by the use of food containing little
y matter and inunction of oil by the skin.

Dr. O. H. Allis gave a short lecture on Why Deformity so frequently follows
acture of the Lower End of the Humerus? and Why Fractures just above or
ow the Knee are so dangerous?—the latter being on account of the danger of
morrhage, the former being due to rotation of the fragments, and vicious union.
e recommended keeping the arm extended during the treatment of fracture of
e condyles of the humerus, in order to prevent the sliding of the fragment.

Dr. Tyson read a short paper upon the Pathology of Albuminuria, which, with
e preceding, was ordered to be published.

Third day.—Dr. Laurence Turnbull read a paper enlarging upon the dangers
Defective Hearing in Locomotive Engineers, and at his recommendation a re-
lution was adopted referring the consideration of the subject to a commission.
e was then appointed Chairman of a committee to bring the subject before the
lroad authorities, and to draft a memorial to present to the State Legislature.

The Address in Medicine by Dr. J. Solis Cohen, in which some new remedies
re discussed and their dangers indicated, was well received, and led to an in-
resting discussion.

Dr. R. J. Levis explained his method of treating Hydrocele and Cystic
umours by the Injection of Carbolic Acid (full strength from 20–60 minims may
e used, half a drachm being usually sufficient).

Dr. Jacob Price read a practical paper on The Importance of Local Treatment
Congestion and Inflammation of the Cervix Uteri in Pregnancy, whose title
dicates its scope. The local application used most frequently consisted of equal
rts of iodine, phenol, and tannin, in four parts of glycerine.

The President appointed Dr. Chas. K. Mills to deliver the Address on Nervous
isorders at the next annual meeting.

The new incumbent, Dr. J. L. Ziegler, was escorted to the presidential chair,
nd the meeting was then adjourned.

The Sanitary Measures proposed by the National Board of Health for the contr of New Orleans during the present Summer.—The National Board, in a letter t Dr. S. E. Chaillé, as Supervising Inspector, has set forth explicit instructions f his guidance. The Board desires to obtain the earliest possible information the existence of yellow fever in New Orleans or its vicinity; to secure free co mercial intercourse between New Orleans and other points, so long as such inte course is unattended with danger; to so arrange matters when such intercour must be restricted as to cause no more interference than is absolutely necessar and in case of the appearance of yellow fever, to co-operate in every way to lim the spread of the disease and to stamp it out if possible. The Board of Heal of Memphis, Tenn., of Shelby County, Tenn., and of Vicksburg, La., ha communicated resolutions to the National Board, requesting early and efficie action on its part, anticipating the coming summer season as a critical one, a requiring clean bills of health, or inspection certificates, issued or countersign by an inspecting officer of the National Board, from all water or land trav where it is deemed necessary, the Shelby County Board of Health also tenderi the quarantine grounds and building on President's Island to the National Boa for use as an inspection station.

The proper enforcement of these ordinances requires that the Supervising I spector shall obtain suitable co-operation and information from the health autho ties and physicians of New Orleans and the river parishes below New Orlean and, in furtherance of this object, the State Board of Health of Louisiana ha tendered the use of a commodious room adjoining its own rooms to the inspecto and have requested his attendance at the meetings of the Board. The details the instructions to the Supervising Inspector comprise regular daily reports fro a National Board inspector at the Mississippi River Quarantine Station, who, cases of difference between himself and the quarantine inspector, furnishes repo to both the Supervising Inspector and the President of the Louisiana Board Health. All reports of deaths, in doubtful and suspicious cases, to be proper investigated, and information as to the presence of cases of yellow fever, or cas which are doubtful or suspicious to be furnished by request of health authoriti of other States and municipalities, *with* the approval of the resident member the Board and independent of the co-operation of the local board. Caution enjoined in determining what constitutes dangerous infection to avoid, as far possible, any undue restriction upon travel or traffic. The inspection of stea boats was to commence with the first of May, as conducted last year; two i spectors, and when necessary two sanitary policemen, being employed. N rigid railroad inspection further than the examination of freights is as yet reco mended. The Supervising Inspector is advised to secure the co-operation of t Louisiana State Board of Health, so as to cause the passage by them of an or nance similar to "resolution No. 6," as passed by the Sanitary Council of t Mississippi Valley, which, in effect, establishes a careful inspection of ships Eadsport, the proper certificate from the inspector of the National Board at Sh Island Quarantine Station to be the only authority which would allow a ves from infected ports to pass without inspection.

The Louisiana State Board of Health, at its meeting of May 19th, adopt the report of Dr. Formento, which was based upon these instructions to D Chaillé, and which renders them nugatory in almost every particular, so far the co-operation of the Board is concerned. Ship Island was not considered sui able for a quarantine station, and if it were, the State Board would not feel wa ranted in using it as such. The only station which the Board thought suitab was the State Mississippi River Quarantine Station, as the best equipped ar

rganized outside of New York. The Board also took occasion to express its rant of sympathy with the Mississippi Valley Sanitary Organization.

The National Board of Health, at its recent meeting, June 1st and 2d, has, it eems, taken no further action upon this condition of things.

—

Scarlet Fever in Charleston.—Dr. F. PEYRE PORCHER, of Charleston, writes s that "a severe epidemic of scarlet fever prevails in this city, many deaths have ccurred in children—the throat being generally involved. As usual the cases ary; sometimes the eruption being not prominent. Deaths have occurred orty-eight hours after the invasion. Many recover. We are of the opinion that afety will be found in early treatment, by efforts to reduce the fever of the first ew hours by fever mixtures, by repeated warm baths, cold sponging to the head nd arms, and application to the throat externally and internally—Labarraque's olution of chlorinated soda and chlorate of potash being admirable in the com- osition of internal applications to the throat. Many have used a solution of sul- hide of sodium as a prophylactic (℥j to water Oj—dessertspoonful t. i. d.), as ecommended first, we believe, by Prof. Elliott, of Sewannee. We know of ree instances where children had the disease, in a mild form, through taking is substance regularly.

"We prefer, and have used for this purpose, a combination of chlorate of potash, uinia, and hyposulphite of soda,[1] which we long since suggested and employed the best prophylactic in diphtheria—to be taken by those exposed to these iseases. It is besides harmless and an excellent tonic. Some children of black ersons have had the scarlet fever here, but there has been a most singular ex- nption in this race. The proportion of whites to blacks seized has, we believe, een as 100 to 1—perhaps much higher than this."

—

International Medical Congress, London, 1881.—The following general ar- ngements for the meeting of the Congress are announced.

An informal reception will take place at the Royal College of Physicians, Pall- all East, on Tuesday afternoon, August 2, from 3 P. M. to 6 P. M., at which the Executive and Reception Committees will meet the members of the Congress. The opening meeting of the Congress will be held in St. James's Great Hall on Wednesday, August 3, at 11 A. M. Entrances in Regent Street and Piccadilly. The other general meetings will be held in the Theatre of the University of London.

The Congress will be organized on Wednesday August 3. In the evening a onversazione at South Kensington Museum will be given by the English mem- ers of the Congress to the foreign members.

On Thursday Aug. 4, an address will be delivered by Prof. Maurice Rey- aud, of Paris, on "Le Septicisme en Médecine, au temps passé et au temps résent." In the evening a banquet will be given at the Mansion House to ertain members of the Congress by the Lord Mayor of London.

On Friday Aug. 5, Dr. J. S. Billings, of Washington, will deliver an address n "Our Medical Literature," and in the evening a conversazione will be given t the Royal College of Surgeons.

On Saturday Aug. 6, there will be no general meeting. The Sections will neet daily from 10 A. M. to 1 P. M. In the afternoon Sir J. D. Hooker will eceive at the Kew Gardens, and Mr. and Mrs. Spencer Wells, at Golder's Hill, Hampstead.

---

[1] ℞.—Chlorate of potash, ʒij; quinia, gr. xv; hyposulphite of soda, ʒij; tr. chloride of iron ʒij; water, ʒvij.—Dessertspoonful t. i. d., used as a preventive.

On Sunday special services will be held at Westminster Abbey by Dean Stanley in the morning, and at St. Paul's Cathedral by Canon Liddon in the afternoon. Sir Trevor Lawrence, M.P., will entertain at luncheon a number of the members at his place at Boxhill, in Surrey.

On Monday Aug. 8, address by Prof. Volkmann, of Halle, and in the evening a dinner will be given to certain members of the Congress by the Society of Apothecaries in their Hall in Blackfriars, also a soirée in the Albert Hall.

On Tuesday Aug. 9, concluding general meeting. Address by Prof. Huxley "The Connection of the Biological Sciences with Medicine." After the conclusion of the meeting the members will be carried by special train to the Crystal Palace, and will be entertained at an informal dinner in the Concert Room. At dusk the fountains will play during a display of fireworks.

Arrangements have been made to enable the members to visit the prominent hospitals, the principal places of public interest, as well as a number of the private galleries in London. Attractive excursions have also been planned for Greenwich, Folkestone, Hampton Court, etc.

—

The Association of Medical Editors met at Richmond, on Monday evening, May 2. In the absence of Dr. J. F. Shrady, President, Dr. Octerlony was called to the chair. Dr. D. S. Reynolds acted as Secretary.

Dr. Shrady's address was read and ordered to be printed.

The Committee on Nominations of Officers for the ensuing year reported as follows: President, Dr. Landon B. Edwards, Richmond, Va.; Vice-President, Dr. Ralph Walsh, of Washington; Secretary, Dr. D. S. Reynolds, of Louisville.

The Association adjourned to meet on Monday evening preceding the next Annual Meeting of the American Medical Association.

—

Health of New York.—The city's mortality has steadily diminished during the last month. The number of deaths for the weeks ending June 4 and 11 was, respectively, 660 and 633, while the numbers for the weeks ending May 1 and 15 were 814 and 822.

The number of new typhus fever cases developed during May was somewhat larger than in April. During the eighth week of the prevailing endemic (ending May 7), there were 28; in the ninth week 14; in the tenth week 34, and in the eleventh week (ending May 29), 13 cases were reported. Smallpox increased slightly in May, in spite of the energetic efforts of the Health Board to check its career.

The quarterly report of the Bureau of Vaccination, recently published, states that in the three months ending March 31, 3616 primary and 19,653 other vaccinations were performed by the Bureau. Several cases of smallpox have been discovered on incoming European steamships, and promptly quarantined. A number of new cases have also been reported in Brooklyn and Jersey City. On June 1 there were 129 cases of variola and 52 of typhus at the Riverside Hospital. Scarlatina has decreased during May, but diphtheria has slowly gained ground, and measles has rapidly increased. German measles has prevailed in almost epidemic form for some months. It has chiefly affected very young children. The heat was less intense in the latter part of May than in the second week of that month, but was sufficient to produce 20 cases of insolation on May 21, 2 of which were fatal.

A compromise street-cleaning bill was passed by the legislature, and received the Governor's signature. Although the time granted by the Governor to the proprietors of the factories on Hunter's Point and Newtown Creek for the abate-

ment of the nuisances connected with their establishment has expired, the odours are as offensive as ever.

—

Indiana State Medical Society met at Indianapolis, May 18th, under the presidency of Thomas B. Harvey, M.D., of Indianapolis. The following officers were elected for the ensuing year: President, Dr. Marshall Sexton, of Rushville; Vice-President, Dr. F. J. Van Vorhis, of Indianapolis; Secretary, Dr. E. S. Elder, of Indianapolis.

—

Illinois State Medical Society held its thirty-first annual meeting at Chicago, May 17th, 18th, and 19th, Dr. George Wheeler Jones, of Danville, President, in the chair. A number of scientific papers were read, and the proceedings were of marked interest. The following officers were elected for the ensuing year: President, Dr. Robert Boal, of Peoria; Vice-Presidents, Drs. A. T. Darrah, of Colono, and Ellen A. Ingersoll, of Canton; Assistant Secretary, Dr. Wm. A. Byrd, of Quincy. It was voted to hold the next meeting at Quincy.

—

Health of Chicago.—An epidemic of Rötheln or German measles is widely spread in Chicago. There were about one hundred cases of it in the Orphan Asylum. No case of death from the disease has been reported. A mild epidemic of diarrhœa, generally referred to the drinking water, also exists. Not long ago the Desplaines River overflowed its banks and a part of its stream entered the Chicago River, flooding the city in some places and carrying filth of the worst description into the lake as far as the Crib, whence Chicago gets its supply of drinking water.

Scarlet fever, diphtheria, and smallpox are still prevalent, and the mortality from each is high.

—

A New Home for Inebriates.—The laying of the corner stone of the "New York Christian Home for Intemperate Men," at the corner of Madison Avenue and 86th Street, took place on June 7. The Home will accommodate about twenty-five men. The cost of the site was $30,000, and the building expenses are estimated at about $60,000. The Home will be constructed of brick and brown stone. It will be four stories high, and its dimensions will be 60×100 feet. There will be private rooms for those patients requiring isolation, bathrooms, sitting-rooms, a library and a chapel. The house will be ventilated, drained, and lighted by the most approved modern methods.

—

Registration of Plumbers.—The bill requiring New York and Brooklyn plumbers to be registered, and to subject all their work to the inspection of the City Health Board, has become a law.

—

The Sick Children's Mission.—A charitable institution under the direction of the Children's Aid Society, has begun its summer work of providing sick children of the lower classes, with gratuitous nourishment, medicines, and medical attendance. Druggists in different parts of the city will furnish medicines free of charge on the presentation of authenticated prescriptions from any of the twelve physicians whose services have been secured by the Mission. Substantial food and suitable delicacies will be furnished by the superintendent of the Mission, who will also provide trained female nurses for cases requiring their services.

Medical and Chirurgical Faculty of Maryland.—The 83d annual meeting o the Faculty was held in Baltimore, April 12 to 16, 1881, Dr. H. P. C. Wilson of Baltimore, President, in the chair. The annual oration was delivered by Dr William Goodell, of Philadelphia. A number of scientific papers were read i the sections. The following officers were elected for the ensuing year: President Dr. Frank Donaldson; Vice-Presidents, Drs. A. H. Bayley and I. E. Atkinson Secretary, Dr. W. G. Regester.

—

Instruction Preparatory to the Study of Medicine in the University of Penn sylvania.—In the assignment of Prof. Joseph T. Rothrock to a Chair of Botan and Dr. Andrew J. Parker to a Chair of Biology in the Towne Scientific School the Trustees of the University have not merely enlarged the curriculum of tha school by the addition of two subjects of great importance, but they have als provided the means of rendering effective the *Sixth Course* as laid down in th general catalogue—*a course preparatory to the study of medicine.* The schem of the course has not been fully elaborated, but, as now published, include English Composition, History, Social Science, Latin, French, German, Physics Chemistry, inorganic and organic, with laboratory practice, Botany, vertebrat and invertebrate Zoology, Mineralogy, and Geology. With the completion o the course, and the passing of appropriate examinations, the degree of Bachelo of Science is conferred.

It will be seen that this course includes a large number of subjects which no only lead to the higher culture so important to the physician, but directly pre pare him for the special studies in human anatomy, physiology, medical chem istry, etc., which should occupy him during the first year of his medical studies as well as furnish the knowledge of physics and mathematics, now so essentia to an intelligent study of certain branches of practical medicine, notably physica diagnosis, ophthalmology, laryngology, and otology.

Too high a value cannot be placed upon such a course. Since the establish ment of scientific schools, both independently and in connection with college courses have been adapted preparatory to the special studies of a large numbe of occupations, including now, with the establishment of the Wharton School o Finance and Economy at the University, the various branches of mercantile pur suit. Not only has the mass of facts which the physician of to-day has to maste increased a hundredfold, but he requires also rare mental qualities to be acquire only by training, in order that he may sift the true from the false, appropriately us the former and discard the latter. Much more, perhaps, to the study of medicin than to that of any other profession should be shaped the previous training an knowledge of the student.

So far as we know, the University of Pennsylvania is the first institution t adopt such a curriculum in its collegiate department, and we cannot but thin that it will commend itself to students who desire to be thoroughly prepared t enter upon a medical course of study.

Still another advantage of such a course may be pointed out. It is constantl occurring that a young man looking forward to the study of medicine feels tha he cannot, on account of his age or want of means or other sufficient cause, tak a full collegiate course before beginning his professional studies, while he ca still spend a year or more at college. To such a one the Sixth Course in th Towne Scientific School affords an admirable opportunity. For by a judicious selection he can avail himself of those branches a knowledge of which will b of the greatest use to him in his medical studies, and thus virtually prolong th period of those studies most advantageously.

With the better grade of material thus afforded, the Medical Department of ıe University hopes to be able also to make still more effective the measures of eform in medical education which it inaugurated four years ago.

—

Jefferson Medical College, Philadelphia.

The continued increase in the size of the Jefferson classes has rendered addi-ɔnal accommodations absolutely necessary; hence, in the recess since the close the winter term, the main building is being remodelled by an extension of the ɔnt, by adding a new story, and by constructing new Laboratory Rooms. By is extension of the front, the seating capacity of each lecture room will be ıterially increased. Thorough ventilation is secured to each lecture room by e introduction of the *Manchester system.* By the addition of another story a w and more commodious dissecting room will be constructed, and the present ssecting room will be converted into a laboratory for experimental therapeutics ıd pharmacy. A large, well-lighted room has been provided for practical ob-etrics, and another with special reference to microscopic work, and for a labora-ry of pathological histology and morbid anatomy.

The Faculty have made important changes in the curriculum. They have ex-nded the winter term about one month, so that the Commencement exercises will xe place at the end of March. Two very important objects to the student have en secured by this change; the weekly number of lectures is reduced in some the branches, which gives the student more time for practical and laboratory ork, and affords him an opportunity to review and digest the lectures. The ıole number of didactic lectures in each department will be about the same as fore, the only difference being the distribution of the lectures over a longer riod.

Courses of practical and laboratory instruction are to be given in connection th all the chairs, and are designed for, and obligatory upon, candidates for the gree—who are not already graduates of other schools—and are free of charge them, except in the case of practical anatomy. Candidates for *partial examı-tion* will be required to attend those branches on which they desire to be ex-ıined at the end of the session.

—

New York Academy of Medicine.—At a meeting of the New York Academy Medicine, held May 19, Dr. E. G. Janeway, the retiring member of the Health ɔard, read a paper upon the present endemic of typhus fever in the city, tracing course from its inception.

At the same meeting Dr. C. C. Lee offered a resolution congratulating Mr. ɔencer Wells upon the completion of his one-thousandth case of ovariotomy, and ɔon his wonderful success in the operation—769 lives having been saved by his dividual efforts. The resolution was unanimously adopted, and the president, r. Barker, appointed to personally present the same to Mr. Wells.

—

Louisiana State Medical Society.—The fourth annual meeting of this society as held at New Orleans, March 30th, Dr. C. W. Smith, President, in the chair. r. J. S. Herrick, Corresponding Secretary, reported that there are in the State 9 physicians, of which 642 are regular, 65 doubtful or unknown, and 92 irreg-ar. The following officers were elected for the ensuing year: President, Dr. A. . Lyon, of Caddo; Vice-Presidents, Drs. D. R. Fox, of Plaquemines, J. P. avidson, of Orleans, A. B. Snell, of Iberville, R. H. Day, of Baton Rouge, V. W. Ashton, of Caddo, J. D. Hammond, of Morehouse; Secretary, Dr. L.

F. Solomon. The next annual meeting will be held in New Orleans on the l Wednesday in March, 1882.

—

New York Health Commission.—The Mayor has nominated Dr. Wools Johnson for the position of Health Commissioner in the place of Dr. E. G. Ja way, whose term of office has recently expired.

—

Iodine Fumigation of the Ear.—Dr. Guéneau de Mussy speaks highly the employment of iodine in affections of the cavity of the tympanum. A v firm little ball of iodized cotton surrounded by wadding is introduced into meatus. The iodine gradually exhales, filling the tympanum with an iodi atmosphere. At the end of from twenty-four to thirty-six hours the cot becomes decolourized and requires renewal.—*Med. Times and Gazette*, A 23, 1881, from *Journal de Thérapeutique*, March 25.

—

Prosecution of Unqualified Practitioners.—Still another unqualified medi practitioner is being prosecuted in New York for unlawfully practising in vio tion of Chapter 513 of the Laws of 1880. The prosecution was instituted by Medical Society of the County of New York.

—

The Seaside Sanitarium, at Rockaway Beach, will soon be opened for the ception of destitute sick children. This institution was founded five years a and has received, during the summer months since its establishment, over 40,0 sick children from the tenement houses. 245 weekly inmates, besides 200 da visitors, can be accommodated at the Sanitarium.

—

Obituary Record.—Died, in Philadelphia, on the 10th of June, aged years, H. Lenox Hodge, M.D., Demonstrator of Anatomy in the Univers of Pennsylvania, and Surgeon to the Presbyterian Hospital and to the Childre Hospital.

Dr. Hodge was the son of the late Dr. Hugh L. Hodge, the eminent Profes of Obstetrics in the University of Pennsylvania. He was educated at the U versity, and graduated in the arts in 1855 and in medicine in 1858. He s sequently served a term as resident physician at the Pennsylvania Hospit During the war he was attached to the Satterlee Hospital, at Philadelphia, a also served in the field with the Army of the Potomac. On the organization the Presbyterian Hospital in 1872 he was appointed on the surgical staff. was elected President of the Pathological Society in 187–. In 1870 he w appointed Demonstrator of Surgery in the University of Pennsylvania.

Dr. Hodge was distinguished for his integrity and uprightness. He was a co scientious student and pains-taking surgeon; and as a teacher he was alwa deeply interested in the welfare of his students, and, in turn, was greatly belov by them. Charitable associations for the relief of the poor and afflicted found him a ready co-worker, and at the time of his decease he was a director in t Pennsylvania Institution for the Deaf and Dumb, and President of the Socie for the Organization of Charity. Of kindly nature and generous heart he w ever ready to give aid and counsel where it was needed, and deeply imbued wi the true religious spirit, its practical lessons were beautifully exemplified in h daily life.

—

To Readers and Correspondents.—The Editor will be happy to receive ear intelligence of local events of general medical interest, or which it is desirab to bring to the notice of the profession. Local papers containing reports news items should be marked.

CORNIL & RANVIER'S PATHOLOGICAL HISTOLOGY—Now Ready.

ANUAL OF PATHOLOGICAL HISTOLOGY. By V. CORNIL, Prof. in the Faculty of Medicine, Paris, and L. RANVIER, Prof. in the College of France. Translated, with Notes and Additions, by E. O. SHAKESPEARE, M.D., Pathologist and Ophthalmic Surgeon to Philada. Hospital, Lecturer on Refraction and Operative Ophthalmic Surgery in Univ. of Pa., and by J. HENRY C. SIMMS, M.D., Demonstrator of Pathological Histology in the Univ. of Pa. In one very handsome octavo volume of over 700 pages, with over 350 illustrations. Cloth, $5 50; leather, $6 50; very handsome half Russia, raised bands, $7.

We have no hesitation in cordially recommending the English translation of Cornil & Ranvier's "Pathological Histology," as the best work of the kind in any language, and as giving to its readers a trustworthy guide in obtaining a broad and solid basis for the appreciation of the practical bearings of pathological anatomy.—*Am. Journ. of Med. Sciences*, April, 1880.

EMMET'S GYNÆCOLOGY—New Edition—Now Ready.

HE PRINCIPLES AND PRACTICE OF GYNÆCOLOGY, for the use of Students and Practitioners of Medicine. By THOMAS ADDIS EMMET, M.D., Surgeon to the Woman's Hospital of the State of New York, etc. Second edition, thoroughly revised. In one very handsome octavo volume of 875 pages, with 133 illustrations. Cloth, $5; leather, $6; very handsome half Russia, raised bands, $6 50.

The appearance of a second edition of this work so short a period justifies the high estimate we ed upon its merits, and must be peculiarly flatng to the author. The high encomiums generally bestowed by the British and European journals bear witness to the fact that Dr. Emmet's work is a valuable and worthy addition to American medical literature.—*Am. Journ. of Med. Sciences*, July, 1880.

ERICHSEN'S SURGERY—Now Ready.

E SCIENCE AND ART OF SURGERY; Being a Treatise on Surgical Injuries, Diseases and Operations. By JOHN ERIC ERICHSEN, Prof. of Surgery in Univ. College, London, etc. Carefully revised by the author from the Seventh and enlarged English edition. Illustrated with eight hundred and sixty-two engravings on wood. In two large and beautiful octavo vols. of nearly 2000 pages. Cloth, $8 50; leather, $10 50; half Russia, $11 50.

the many treatises on Surgery which it has been ask to study, or our pleasure to read, there is which in all points has satisfied us so well as classic treatise of Erichsen. His polished, clear e, his freedom from prejudice and hobbies, his rpassed grasp of his subject, and vast clinical rience, qualify him admirably to write a model text-book. When we wish, at the least cost of time, to learn the most of a topic in surgery, we turn, by preference, to his work. It is a pleasure, therefore, to see that the appreciation of it is general, and has led to the appearance of another edition.—*Med. and Surg. Reporter*, Feb. 2, 1878.

LEISHMAN'S MIDWIFERY—Now Ready.

YSTEM OF MIDWIFERY, INCLUDING THE DISEASES OF PREGNANCY AND THE PUERPERAL STATE. By WILLIAM LEISHMAN, M.D., Regius Professor of Midwifery in the University of Glasgow, etc. Third American edition, revised by the author, with additions by JOHN S. PARRY, M.D., Obstetrician to the Phila. Hospital. In one large and very handsome octavo volume of 733 pages, with over 200 illustrations. Cloth, $4 50; leather, $5 50; half Russia, raised bands, $6.

e gladly welcome the new edition of this excelltext-book of midwifery. The former editions been most favorably received on both sides of Atlantic. In the preparation of the present edithe author has made such alterations as the ress of obstetrical science seems to require, and annot but admire the ability with which the task has been performed. We consider it an admirable text-book for students during their attendance upon lectures, and have great pleasure in recommending it. As an exponent of the midwifery of the present day it has no superior in the English language.—*Canada Lancet*, Jan. 1880.

THE NATIONAL DISPENSATORY—Second Edition—Now Ready.

E NATIONAL DISPENSATORY, CONTAINING THE NATURAL HISTORY, CHEMISTRY, PHARMACY, ACTIONS AND USES OF MEDICINES, including those recognized in the Pharmacopœias of the United States, Great Britain, and Germany, with numerous references to the French Codex. By ALFRED STILLÉ, M.D., LL.D., Prof. of the Theory and Practice of Medicine and of Clinical Medicine in the Univ. of Penna., and JOHN M. MAISCH, Ph.D., Prof. of Mat. Medica and Botany in the Phila. Coll. of Pharmacy, Secy. to the Am. Pharmaceutical Association. Second edition, thoroughly revised, with numerous additions. In one very handsome octavo volume of sixteen hundred and ninety-two pages, with two hundred and thirty-nine illustrations. Extra cloth, $6 75; leather, raised bands, $7 50; half Russia, raised bands and open back, $8 25.

is evidence of success, seldom paralleled, shows ly how well the authors have met the existing s of the pharmaceutical and medical professions. ifying as it must be to them, they have embraced opportunity offered for a thorough revision of whole work, striving to embrace within it all that at have been omitted in the former edition, and hat has newly appeared of sufficient importance ng the time of its collaboration, and the short inal elapsed since the previous publication. After having gone carefully through the volume we must admit that the authors have labored faithfully, and with success, in maintaining the high character of their work as a compendium meeting the requirements of the day, to which one can safely turn in quest of the latest information concerning everything worthy of notice in connection with Pharmacy, Materia Medica, and Therapeutics.—*Am. Journ. of Pharmacy*, Nov. 1879.

FOTHERGILL'S HANDBOOK OF TREATMENT—Second Edition—Just Ready.

E PRACTITIONER'S HANDBOOK OF TREATMENT; OR, THE PRINCIPLES OF THERAPEUTICS. By J. MILNER FOTHERGILL, M.D. Edinb., M.R.C.P Lond., Asst. Physician to the West London Hospital; Asst. Physician to the City of London Hospital, etc. Second edition, revised and enlarged. In one very neat octavo volume of about 650 pages. Cloth, $4; very handsome half Russia, raised bands, $5 50.

HENRY C. LEA'S SON & CO.—Philadelphia.

PROSPECTUS FOR 1881.

THE AMERICAN JOURNAL OF THE MEDICAL SCIENCES.

In commencing its sixty-first year, the publishers of the "AMERICAN JOURNAL OF THE MEDICAL SCIENCES" have much pleasure in assuring its wide circle of readers that at no period has it had the prospect of a more extended field of usefulness.

For 1881 the "American Journal" has the promise of its usual variety of important contributions from distinguished members of the profession in all parts of the country. Special attention will be bestowed, as heretofore, on its Bibliographical Department and Quarterly Summaries to keep its subscribers informed as to all subjects of professional interest from every quarter.

With its attendant periodical, "THE MEDICAL NEWS AND ABSTRACT," it combines the advantages of the elaborate preparation which can be given to a quarterly, and the prompt conveyance of intelligence by the monthly, while, the whole being under a single editorial supervision, the subscriber is secured against the duplication of matter inevitable under other circumstances. These efforts the publishers seek to second by offering these periodicals at a price unprecedentedly low—a price which places them within the reach of every practitioner, and gives the equivalent of three large octavo volumes for the comparatively trifling cost of FIVE DOLLARS *per annum*.

The "NEWS AND ABSTRACT" consists of sixty-four pages monthly, in a neat cover. It contains a CLINICAL DEPARTMENT in which will be continued the series of ORIGINAL AMERICAN CLINICAL LECTURES, contributed by gentlemen of the highest reputation throughout the United States, together with a choice selection of Foreign Lectures and Hospital Notes and Gleanings. Then follows the "MONTHLY ABSTRACT," systematically arranged and classified, and presenting five or six hundred articles yearly; each number concluding with an EDITORIAL and a NEWS DEPARTMENT, giving current professional intelligence, domestic and foreign, the whole fully indexed at the close of each volume, rendering it of permanent value for reference.

The subscription price to the "NEWS AND ABSTRACT" will be Two Dollars and a Half per annum, invariably in advance, at which rate it will rank as one of the cheapest medical periodicals in the country. But it will also be furnished, free of all charge, in commutation with the "AMERICAN JOURNAL OF THE MEDICAL SCIENCES," to all who remit FIVE DOLLARS in advance, thus giving to the subscriber, for that very moderate sum, a complete record of medical progress throughout the world, in the compass of about two thousand large octavo pages.

These terms may be recapitulated as follows:—

TERMS FOR 1881.

The AMERICAN JOURNAL OF THE MEDICAL SCIENCES, published quarterly (1150 pages per annum), and
The MEDICAL NEWS AND ABSTRACT, published monthly (768 pages per annum),
} **Five Dollars per annum, in advance.**

SEPARATE SUBSCRIPTIONS TO

The AMERICAN JOURNAL OF THE MEDICAL SCIENCES, when not paid for in advance, } **Five Dollars.**
The MEDICAL NEWS AND ABSTRACT, invariably in advance, Two Dollars and a Half.

*** Advance-paying subscribers can obtain, at the close of the year, cloth covers, gilt lettered, for binding the volumes of the JOURNAL (two annually) and the NEWS AND ABSTRACT (one annually), free by mail, on remitting ten cents for each cover.

The safest mode of remittance is by bank check or draft, or postal money order drawn to the order of the undersigned. Where these are not accessible, remittances for the "JOURNAL" and "NEWS AND ABSTRACT" may be made at the risk of the publishers by forwarding in REGISTERED letters. Address

I. MINIS HAYS, A.M., M.D.

PHILADELPHIA:
HENRY C. LEA'S SON & CO.
1881.

PUBLISHED MONTHLY AT $2.50 PER ANNUM IN ADVANCE.
Furnished in conjunction with the Quarterly American Journal of the Medical Sciences (in all nearly 2000 octavo pages) for $5.00 in advance.

ered according to the Act of Congress, in the year 1881, by HENRY C. LEA'S SON & Co., in the Office of the Librarian of Congress. All rights reserved.

SOLD ONLY BY SUBSCRIPTION.

HOLMES'S SYSTEM OF SURGERY—Americanized.

A SYSTEM OF SURGERY

THEORETICAL AND PRACTICAL.

IN TREATISES BY VARIOUS AUTHORS.

EDITED BY

TIMOTHY HOLMES, M.A.,

Surgeon and Lecturer on Surgery at St. George's Hospital, London.

AMERICAN EDITION, THOROUGHLY REVISED AND MUCH ENLARGE

BY

JOHN H. PACKARD, M.D.,

Surgeon to the Episcopal and St. Joseph's Hospitals, Philadelphia.

Assisted by a Large Corps of the Most Eminent American Surgeons.

In three large and very handsome imperial octavo volumes of about 1000 pages each, v
over 1000 illustrations on wood, and 18 lithographic plates, beautifully colored.

	Cloth.	Leather.	Half Russia.
Per volume	$6.00	$7.00	$7.50
Per set	18 00	21.00	22.50

VOLUME I. (*now ready*) contains GENERAL PATHOLOGY, MORBID PROCESSES, INJURIES GENERAL, COMPLICATIONS OF INJURIES AND INJURIES OF REGIONS.

VOLUME II. (*shortly*) contains DISEASES OF ORGANS OF SPECIAL SENSE, CIRCULATORY S TEM, DIGESTIVE TRACT AND GENITO-URINARY ORGANS.

VOLUME III. (*shortly*) contains DISEASES OF THE RESPIRATORY ORGANS, JOINTS, BONES. MUSCLES, OPERATIVE AND MINOR SURGERY, GUNSHOT WOUNDS, HOSPITALS AND MIS LANEOUS SUBJECTS.

This great work, issued some years since in England, has won such universal confid wherever the language is spoken, that its republication here, in a form more thorou adapted to the wants of the American practitioner, has seemed to be a duty owing to profession.

To accomplish this the aid has been invited of the most distinguished gentlemen in e part of the country, and for more than a year they have been assiduously engaged u the task. Though the original work presents the combined labor of the most emi members of all the most prominent schools of England, yet the lapse of time since appearance of the last edition, the progress of science, and the peculiarities of Amer practice have rendered necessary a most careful, thorough and searching revision. E article has been placed in the hands of a gentleman specially competent to treat its subj and no labor has been spared to bring each one up to the foremost level of the times to adapt it thoroughly to the practice of the country. In certain cases this has rend necessary the substitution of an entirely new essay for the original, as in the case of articles on Skin Diseases, and on the Diseases of the Absorbent System, where the vi of the authors have been superseded by the advance of Medical Science, and new arti have therefore been prepared by Drs. Arthur Van Harlingen and S. C. Busey respectiv So also in the case of Anæsthetics, in the use of which American practice differs from of England, the original has been supplemented with a new essay, by J. C. Reeve, M treating not only of the employment of ether and chloroform, but of the other anæsth agents of more recent discovery. The same careful and conscientious revision has b pursued throughout, leading to an increase of about one-fourth in matter, while the se of illustrations has been more than doubled, and the whole is presented as a compe exponent of British and American Surgery, adapted to the daily needs of the wor practitioner.

In order to bring it within the reach of every member of the profession, the five volu of the original have been compressed into three by employing a double-columned impe octavo page, and in this improved form it is offered at less than one-half the price of original. It is beautifully printed on handsome laid paper, and forms a worthy compa to REYNOLDS'S "SYSTEM OF MEDICINE," which has met with so much favor in every sec of the country.

The work will be sold by subscription only, and in due time every member of the pro sion will be called upon and offered an opportunity to subscribe.

Clinical Lectures.

THE TREATMENT OF THE NIGHT-SWEATING OF PHTHISIS.

A CLINICAL LECTURE DELIVERED AT THE PENNSYLVANIA HOSPITAL.

BY J. M. DA COSTA, M.D.,

PROFESSOR OF PRACTICE OF MEDICINE AND OF CLINICAL MEDICINE AT THE JEFFERSON MEDICAL COLLEGE; PHYSICIAN TO THE PENNSYLVANIA HOSPITAL.

[Reported by Frank Woodbury, M.D.]

GENTLEMEN: The first case to which this morning I shall call your attention is that of Mary E., 26 years of age, unmarried. There is a bad family record; the mother is supposed to have died of pneumonia; more likely it was a tubercular affection, as she was ill for some time. The patient herself has never been in very robust health, and last August she had, it is said, an attack of intermittent fever, which lasted for four weeks. The menses were regular until April, since which time they have not appeared; and for the last three months she has had a troublesome cough, night-sweats, fever, and has lost forty pounds in weight. There has been no hæmoptysis. She has been obliged to work all the time, until she found herself absolutely unable on account of shortness of breath and debility. One point I want to make here clear to you—the thoracic symptoms came on suddenly, beginning in November, as a chest-cold following exposure.

Upon admission, she was found to have a cough and a troublesome hectic fever. Under the left clavicle the percussion-note was dull, and upon auscultation blowing respiration, and some moist râles indicated the advanced tubercular deposit. Her feet were œdematous, the urine was normal.

As regards treatment, she has been placed, since admission, upon pills of quinia, digitalis, and opium, and on these, with a liberal diet, she somewhat improved. But there was an element in the case which did not improve—her night-sweats—until, after being in the hospital for some time, the gentleman who had charge of her ordered her atropia (gr. $\frac{1}{60}$), to be given at night. The effect was most evident in putting a stop to one annoying symptom, the habit of getting up frequently at night to urinate.

Upon the sweating the influence of the drug was not so positive. It is, indeed, noted that even under one-sixtieth of a grain of atropia each night, with quinia, iron, and good food, the night-sweats continued, and the atropia was stopped. This note was made on the 13th of January, the atropia having been begun on the 8th.

I will not go on with the history of the case further than to say that a troublesome diarrhœa broke out about this time, and was met with bismuth and opium. The diarrhœa only for a time improved; she was then with better effect placed upon oxide of silver and opium. But what became of the sweats? They persisted. The atropia, as I have said, was discontinued after about ten days' trial, having produced some, but not a striking, effect; after the diarrhœa appeared it was not considered advisable to continue it. Upon the 28th of January, she was placed upon salicylic acid. It was noted at this time that the other symptoms were better; the diarrhœa no longer existed.

But what I wish to call your attention particularly to here, is the subsequent course of the fever and of the sweats, how influenced by salicylic acid, and what other remedies were made use of. The first effect of the salicylic acid given in doses of thirty-grains at night was an undoubted influence upon the sweats; they were less, they became localized more about the neck and face, and far less general. She slept well, her cough also was somewhat better, which cannot be attributed to the salicylic acid, but to the steady improvement in the nutrition, under good diet and the pills of quinia, opium, and digitalis, which kept the fever temperature in check. I exhibit to you the chart, which is the daily axillary thermometric record. You see it is sometimes as high as 103° or 104° in the evening and nearly normal the next morning; it seems almost like the record of remittent fever, so great is the difference between morning and evening. Her affection was therefore characterized by irregular fever, or rather by what is the regular fever of this type of pulmonary disease. The highest point reached was on the 4th of February (104.6° in the afternoon), while she was still taking salicylic acid.

I found that while the acid had some effect, it did not influence the sweats sufficiently, and a material change in the treatment was decided upon. I then put her upon a remedy to which I wish to call your attention—a remedy which I have been using in this hospital for the last three years—ergotine. The salicylic acid being suspended, she was ordered ergotine, two grains in pill, three times a day. The results were successful. I do not tell you that the salicylic acid had no effect, for it had, but the ergotine had a better effect. What is particularly observable is that the temperature has declined, the range is lower, and, indeed, it has been on several occasions lately a normal temperature. The highest point reached since taking the remedy is 101½°, the lowest 98½°.

Now having explained the case, and especially the treatment of the symptom for which I brought her before you, let us make an examination of her present state in order to compare it with her previous condition.

Her temperature this morning is 98½°, normal; last night it was 100½°. She says that she had a slight sweat last night about the face and neck; it was, however, of short duration, and nothing like as profuse as it has been. This was the first sweating for nearly a week. There has not even been any moisture.

As regards the physical signs, you observe dulness on percussion, still very marked at the left apex. Upon auscultation, I perceive harsh respi-

ration, almost bronchial, with distinct prolonged expiration. Harsh respiration extends all over the lung, with here and there moist crackling, but this is particularly noticed at the upper part of the lung, both anteriorly and posteriorly. On the right side, the vesicular murmur is somewhat harsh, only there is no marked dulness, except immediately under the clavicle. In other words, the signs of consolidation are here very light.

Her appetite is better, though the tongue is still somewhat coated. She has, since Feb. 13, been taking the syrup of the iodide of iron in twenty-drop doses, the pills of quinia, digitalis, and opium having been stopped at that time. The ergotine has been continued, and has been increased to four times a day. [Let me add that sweating was never again marked. The patient died about a month afterwards from exhaustion.]

Case II.—There was another case similar to this, occupying bed No. 1 which I shall bring before you. I will give you very briefly her history. She has a tubercular deposit, especially in the right lung, of about one year's standing; she lost a brother by tubercular consumption. The history is that of a gradual disease with considerable wasting, purulent expectoration, and softening just beginning. Her most troublesome symptom was night-sweating. For this she was first ordered atropia, one-sixtieth of a grain at night on the 21st of December of last year, and the remedy was continued until Jan. 3, 1881, at first with good results, but finally losing its effect. Oxide of zinc with hyoscyamus, aromatic sulphuric acid, strychnia, quinia, all answered partially for a time, but only partially, and salicylic acid, ten grains three times daily, was used for four or five days (the evening temperature being about 101°), with some, but not with very decided result. On Feb. 6, ergotine, two grains four times daily, was ordered, while the same general tonic and nutrient treatment was continued. After the second night she began to improve, and by the 13th the sweats had stopped, with the exception of the night of the 12th, when there was a little sweating on the face and breast. From this time to the 28th, she took the medicine far less regularly, though she remained more or less under its influence. For twenty days there was no night-sweating, only occasionally a little moisture about the face and breast; with the stoppage of the exhausting discharge, her general health improved markedly. Unfortunately, by the 5th of March, the remedy began to lose its effect, and she soon afterwards left the hospital. She returned in about one month for a few weeks, and the night-sweats, which, however, had never been so bad as prior to the ergotine treatment, were for a time again very favourably influenced by this agent.

I shall now call your attention to a couple of cases for some time under my observation in the men's medical, in which also profuse sweating was a very distressing symptom.

Case III.—John McC., bed 37, a case of pneumonic phthisis of left lung, followed by tubercular complication of both. There is beginning softening at left apex; the cough is most troublesome, so are the night-sweats. They have been going on for eight months, and gaining in intensity. The patient is weak, but his disease was not actively progressing; the temperature was but little above the normal, and sometimes normal. A treatment by pills of quinia, opium, and digitalis, and by the compound syrup of the phosphates improved his cough and general condition, but had no influence on the sweats. A granule of one-sixtieth of a grain of atropia at night arrested them promptly, but though continued for a week had no permanent effect on them; oxide of zinc was

temporarily of service; strychnia, one twenty-fourth of a grain three times a day, did better; and, being free from sweats for nearly two weeks, and under the effect of his general treatment, he improved decidedly. But the sweats returned, and he was placed, instead of on the strychnia, on ergotine, two grains three times daily. After the second night they were very much better, but they did not stop until the fourth. They were absent for a week, then he had a rather profuse sweat during a restless night. The ergotine was now given four times daily, and prevented further sweating. After about a week of this increased dose it was suspended, except occasionally, and though the disease was progressing, sweating was not again a prominent symptom.

CASE IV.—In this man of fifty years of age, a large cavity was found at the left apex, and, when he came under observation, decided night-sweats had existed for two months. The evening temperature did not exceed 102°. He passed six pints of urine daily of spec. gr. varying from 1007 to 1010, and free from albumen and sugar. Chlorodyne benefited his cough very much; the night-sweats were markedly and permanently controlled by ergotine in two-grain doses three times daily, which also strikingly lessened the quantity of urine passed.

But it is needless to multiply cases. I merely brought these forward because they were all marked instances of the symptom I wish to discuss with you—the night-sweating of phthisis; and they illustrate it in some of the various forms and different stages of the disease. Now sweating in phthisis is both an annoying and a serious symptom. It very often happens in the early morning hours, and the patient is languid all day from the drain. It may follow the decline of the paroxysm of the hectic fever, but also occurs in those who have but little if any fever, and certainly nothing like hectic paroxysms. To arrest it is not only to give the patient comfort, but to save his strength and thus to retard the progress of the disease. The remedies which influence the destructive malady and improve nutrition, restrain it; but they do so slowly, and we turn, therefore, naturally, to agents which, while they act much more quickly in so doing, assist at the same time the influence of the general treatment. A great many of these remedies are empirical: some take into account the supposed pathology of the sweats, and apply the fine experimental therapeutical research of the laboratory to the benefiting of a serious symptom. We might do this with even more accuracy if the pathology of the occurrence were better understood; if it were known how it is that the morbid conditions act on the sweat-centres which are so profoundly disturbed. Yet both physiology and pathology are in this matter of sweating, alike in health and in disease, still a good deal in the dark, notwithstanding such excellent observations as those of Luchsinger, Nawrocki, and Vulpian, and the increasing knowledge concerning the sweat-centres situated in the medulla and adjacent cord.

But I shall not wander away from my subject, the treatment of night-sweats in the light of actual experience. And here I shall select for discussion the action of such remedies as are valuable yet comparatively new, and not of such tried veterans as oxide of zinc, the mineral acids, tincture of iron, and decided doses of quinia.

Yet before I examine into the value of the medicinal substances I will allude to some subjects connected with clothing and with bathing which I know are constantly ignored and are yet of importance. The clothing

is often much too heavy. Take a case just seen in the female ward. Her night-sweats were kept up by heavy clothing. We found her wrapped up in shawls; she said that she could not take them off because she felt chilly; she felt chilly, and next was sweating, then sweating and next chilly, and so she wanted still more clothes, and the sweating was kept up. I wish then to impress upon you that one of the first things to be taken care of in the management of night-sweats is to see that the patient's clothing is light, particularly that he be not weighted down with heavy bedclothing; and very often you may by paying attention to this simple means prevent or certainly very much lessen the exhaustive perspirations. In addition, direct your attention to the state of the skin; let the patient take a daily slightly astringent sponge-bath, having in the water alum, rock-salt, or even whiskey or alcohol, or let him be sponged with quinia dissolved in whiskey or alcohol, or with water to which a small amount of solution of ammonia has been added; and follow this by friction to give a healthy glow to the skin. You will find that in some persons very hot water checks the excessive sweating, but in the majority moderate friction, following astringent washes is better.

In reviewing the remedies with which the last few years have made us familiar, we find quite a number with which the experiments and the sagacious observations of Dr. William Murrell have acquainted us. In the *Practitioner* for 1879 and 1880 they are detailed in full, and a summary of the use of them might be thus made, which I think will be borne out by the experience of any one who will try them: *Muscarine* stops sweating on the second or third night without causing abnormal dryness of the skin. It is best given in three doses, at the interval of an hour, in quantity not less than five minims of a one per cent. solution of a liquid extract. *Picrotoxine* produces, generally, no effect the first night; may be given solely at bedtime, either in pill of one-sixtieth of a grain, or in solution with a little glacial acetic acid. *Nitrite* of *amyl*, a good, though not a very certain or pleasant agent. Dose from one to three minims.

Dover's powder, although it cannot be called a new remedy, since its use was advocated many years since by Stokes, has come again into prominence, and in doses of two to ten grains at bedtime undoubtedly shows power in controlling colliquative sweats. I wish I could give you a theory that accounts satisfactorily for its action. But I have none in my own mind to which I turn unfalteringly. There is the same difficulty in explaining its influence on pathological sweating that there is with all the agents, as, for instance, picrotoxine and jaborandi, which are excretors of perspiration. I suppose the solution will be found in their peculiar action on the sweat-centres; but we are still remote from it. Nor can I exactly tell you in what cases Dover's powder does better than the astringent class of remedies. I think, however, that it is in cases with decided rise of temperature. I am persuaded that it is to the ipecac in the composition that much of the good is due. For I have tried giving ipecac in small doses frequently repeated, about one drop of the wine every second hour, and have seen it have a most undoubted influence on the morbid discharge. In these small doses its action may be that of a tonic to the sweat-centres in the nervous system.

I have just referred to *jaborandi*. I shall presently explain to you how I have for some years used it, added in small doses to atropia, to correct some of the unpleasant effects of this. And it is while so using it that I began to be aware of its influence on night-sweating of phthisis. But I

only half knew the fact until I read the interesting observations of Dr. John M. Keating,[1] who, prescribing it in small quantities of the infusion, found it answer extremely well; he believes that it contracts the capillaries, and thus explains its action. Dr. William Murrell, whom I have already quoted, has administered it or pilocarpine in thirty-three cases, in all stages of the disease. Of pilocarpine the dose employed was generally $\frac{1}{20}$ of a grain, either at bedtime or three or four times daily. It acts somewhat slowly, but is said to be very efficacious, and even to lead to permanent results. I confess that I have not formed so high an estimate of it. Indeed, I cannot say that, given by itself, it ranks with me very high.

Salicylic acid has attracted attention more for its supposed influence on the febrile conditions of phthisis than as a remedy for the sweating. Still it has been so employed. Köhnhorn[2] has recommended dusting with salicylic acid three parts, ten of starch, and eighty-seven of talc earth, the entire surface of the body. Internally salicylic acid has been resorted to for night-sweats by my colleague, Dr. Hutchinson, and from him I learnt its use for that purpose. In some cases it seemed to have a good influence, but the cases are not yet numerous enough to warrant a definite conclusion as to its merits.

I was led to use *physostigma* for the same reasons which led me to investigate jaborandi, to try and counteract with it some of the disagreeable effects of atropia, while preserving its useful ones. But in doing so it was first necessary to observe whether calabar bean had in itself any influence on night-sweats; and during the winter of 1879–1880, with the active and zealous aid of Dr. Henry M. Wetherill, at that time the resident physician in my wards, we tested the matter in this Hospital. We found that calabar bean had an influence. To cite a few of the observations: In a man with advanced tubercular consumption, attended with profuse night-sweats, two minims of fluid extract of physostigma were given; he was sweating at the time; his respirations were 30; the pulse, 120; the temperature, 100°. In an hour afterwards the skin was almost dry; respirations were 24; the pulse was 104; the temperature, 96.6°; it rose in two hours after this to 97.8°. There had been no unpleasant effects, except great thirst. In another case we first noticed the sweating carefully, while a placebo only was given. It came on profusely at 12 P. M., and while profuse, the respirations were 32, pulse was 122, the temperature, 97°; the sweating lasted four hours; as it passed away, the respirations were 28, the pulse, 114, the temperature, 99.8°. At the same period of the next twenty-four hours, and when the sweating had fairly begun, although the temperature then was 99.5°, a dose of two minims of the fluid extract of calabar bean checked the sweating in an hour and a half, the temperature rising to 100.6°. In a third case of marked phthisis with night-sweats, the temperature before the sweats at 3 P. M. was 100.5°; in an hour afterwards, with a profuse sweat it had declined to 98.6°; four minims of the fluid extract were then given, the sweat was completely checked in an hour, the temperature rising to 99°; there was no decided effect on the pupil, and no unpleasant symptom. In a fourth case, the profuse early morning perspirations were arrested in two hours by the same dose, the pupils being slightly contracted, the pulse becoming less strong, the temperature declining from 100° to 97.6°. Now, both in these and other cases the remedy was given in two minim doses, once or

[1] Phila. Med. Times, June, 1877. [2] Berliner klin. Wochenschrift, No. 1, 1880.

twice in the evening, sometimes four minims at one dose (the preparation being of the strength of one of the bean to a minim of fluid), and the sweating was undoubtedly to a great extent prevented; but only in one instance was the effect at all permanent; and, on the whole, while the action of calabar bean is undoubted, it is decidedly inferior to atropia and to ergot.

I shall now pass to the two remedies which I think pre-eminent—atropia and ergotine. The use of *atropia* is now so widely known, and it has been so much resorted to, that, although having employed it systematically in this Hospital for night-sweats for years before it began to attract general attention,[1] we may claim for it the strong partiality of early knowledge, I shall only state that it is at present accepted as the most potent agent we possess to control inordinate sweating, particularly in consumption. Not one of the remedies which I have mentioned to you has, in my opinion, anything like its power. But atropia has a most serious drawback. Even the smallest dose, to be effective, $\frac{1}{80}$ of a grain, produces such a dry mouth and throat that it often keeps the patient awake, and, in not a few instances, increases his cough. Duboisia, so much like atropia, even in its influence on sweating, has the same unfortunate effect. Local remedies, such as sucking pieces of ice, chewing chamomile flowers or sassafras pith, sipping infusions of slippery elm, only afford partial relief, moreover they prevent sleep. And the inconvenience witnessed led me to a series of observations, that I have here carried on for the last four or five years, to find among the agents which possess a physiological antagonism to atropia one which, without materially, if at all, diminishing its action on the skin, might mitigate its influence on the salivary secretion. Not to detain you too long, I will speak particularly of strychnia, calabar bean, and jaborandi, added to belladonna or atropia. With reference to strychnia, it is in many respects not antagonistic to belladonna; one, indeed, may promote the activity of the other; and I was led to hope all the more from a combination being effective with a smaller dose of the belladonna or atropia, and was induced to persevere with my observations after reading Lauder Brunton's remarks on the unaided action of strychnia in the night-sweating of phthisis.[2] But this expectation has only been partially realized. The atropia preponderates, and even in decreased doses dries the throat.

From both calabar bean and jaborandi we get better results. I have already laid before you my observations with the former given alone, and you will recall the fact, which has been made very apparent by the experiments of Fraser, Bartholow, and other investigators, that in most respects it is a true antagonist to atropia. It leads to an increased flow of saliva, and is said to increase the perspiration. But it certainly does not do so in phthisis, whatever be the explanation; and if you add gr. $\frac{1}{8}$ to gr. $\frac{1}{4}$ of the solid extract, or two to three minims of the fluid, to $\frac{1}{80}$ to $\frac{1}{40}$ of atropia, you preserve or heighten the good effect of the latter, and lessen its evil ones. Still better I find is jaborandi. The drug, you are aware, illustrates in its action a complete antagonism to atropia and produces profuse secretion from the salivary glands. Yet, though in health it promotes the most active discharge from the skin, its powers in small doses to arrest morbid sweating have been abundantly proved, and added in small doses to atropia, say ten to fifteen drops of the ordinary

[1] Clinical Lecture, Phila. Med. Times, Feb. 15, 1871; and Ib., Oct. 1872.
[2] St. Bartholomew's Hospital Reports, 1879.

fluid extract to $\frac{1}{60}$ of a grain, or, as I have often done, a dose of thi quantity given two hours in advance of the atropia, and repeated with it, the sweats will be as well influenced, while the discomfort arising from the dryness of the mouth will be greatly diminished. The effect o the combination is undoubted, and its power is not confined to the night perspirations of phthisis. You will remember the man in bed 34 with chronic pleurisy and sweats, which here were increased by the dose of jaborandi he was taking to reduce the effusion. $\frac{1}{60}$ of atropia at nigh relieved the night-sweating completely, gave him in so doing comfortabl nights, and enabled us to continue the other treatment. He had no in convenience with his throat, until we suspended the jaborandi, placin him on iron, but continuing the atropia ; yet when this parched his throat a single dose of jaborandi quickly relieved him.

Still we cannot, even by the combination of jaborandi with atropia always remedy the annoyance. It is difficult to hit upon the exact dose and the atropia will at times overpower the jaborandi. I have thus bee led to look for an agent which should possess something of the certaint and permanence of action of atropia without its drawbacks, and I thin I have found it in *ergotine.* My first observations, made some years ago were with the fluid extract of ergot, but I have abandoned this for ergo tine as better and more easily administered. The power ergot has of con tracting the arterioles and of checking excessive discharges suggested it use, and the results have been very satisfactory. Ergotine was prescribe in the cases with which I introduced the subject to your attention thi morning, and I could give you many more in illustration, showing it effects in the various forms of phthisis. The dose of ergotine I emplo is usually two grains three or four times daily, and by the second nigh the influence begins to manifest itself. The remedy may then be continue and gradually abandoned; it produces no annoyance or discomfort wha ever, and its good effects persist after it is withdrawn. It will fail o lose its effect as every other remedy will fail or lose its effect in the trea ment of such an unrelenting disease, but the proportion of failures small compared with that of the successes.

You will ask for a comparative estimate between it and atropia. Fo immediate results ergotine is far inferior. If you see a patient in th morning in whom you wish to prevent a violent sweating in the evening there is no remedy which for promptness can compare with atropia there is, moreover, no remedy which is so potent in cases where th skin pours forth quantities of fluid. But where such speedy and decisiv action is not demanded, where you are obliged to keep up a remedy fo some time, where to do so with atropia becomes very difficult or occasion first discomfort and then actual distress, you have then in ergotine a agent to which you can turn with confidence. Less prompt, perhap less certain, it is better borne, and shares with atropia the valuable powe of often making a durable impression. Nay, I have seen it do so whe atropia has failed.

Gentlemen, I have now laid before you the results of a series of in quiries into a matter of deep and practical interest. In summing it u in your minds you will see that there are many articles, some of whic do the work required of them well, others not so well. It is not easy t say which agent in a given case will succeed best, and you ought to be a accurately as possible acquainted with the action of many. Speakin generally there are remedies which act as astringents and as arresting th

secretion; there are others which under normal circumstances promote perspiration, and allay the morbid sweating, either because they substitute a normal discharge for an abnormal one, or, what is more likely, because given in small doses they tone up and gently stimulate to healthy action the sweat-centres and the respiratory centres. But whatever the explanation, the latter class of remedies, Dover's powder, jaborandi, picrotoxine, are, on the whole, greatly inferior to the former, and not so permanent. And it is permanency of action at which we must, as far as possible, aim. This gives time for the general treatment to take effect; it arrests a serious drain, and what I have endeavoured to show you in the case of several of the agents, if we once succeed in making for more than a very short period a decided impression, the annoying, dangerous symptom may be altogether relieved or at least for ever broken in intensity.

CLINICAL REMARKS ON TWO CASES OF TUMOUR OF THE BLADDER.

Delivered at the University College Hospital on January 17th.

By BERKELEY HILL, F.R.C.S.,
Professor of Clinical Surgery in University College, London.

GENTLEMEN: There have been recently in our wards some excellent examples of those rare affections, tumours of the bladder. I propose to-day to select for remark two of these cases, partly for their rarity, partly because we have the morbid growths themselves for your inspection.

In speaking of tumours, I mean true morbid growths; and exclude those swellings of the hypertrophied prostate met with in certain old men, which, by their deformity, produce a train of suffering sufficiently acute. During the year last past, we have had several such patients in our wards, affording examples of some or other of the consequences of hypertrophy of the prostate. But with such cases it is not my intention to occupy your time to-day.

The list of morbid growths comprises:—

1. *Fibrous polypi*, fibrous outgrowths from the surface of the bladder, an extremely rare affection, described by Civiale and one or two others. Of these growths, a few specimens are preserved in museums.

2. *Scirrhus and encephaloid* of the walls of the bladder, growths nearly always secondary to cancerous disease elsewhere, but occasionally occurring primarily in this situation.

3. *True epithelial cancer*, beginning in and slowly extending in the wall of the bladder.

4. *Villous tumour*.

These growths may all begin in the bladder itself; but affections of other organs may lead to projections into, and invasions of, the bladder, as, for example—

5. *Malignant disease of the prostate*, generally encephaloid in character.

6. *Tubercular disease* of the vesiculæ seminales, or of the vesiculæ seminales and prostate.

At this moment, there is an old man in Ward 10, seventy years of age, and in fair general health, who has, for the last eighteen months, been unable to void any urine by natural efforts. He draws it off through the catheter, by which the urethra is easily traversed until the prostate is reached, where, if not well curved

or very supple, it stops short. There is no suprapubic dulness; but, when the prostate and floor of the bladder are examined *per rectum*, an irregular mass of stony hardness is felt; one firm nodule projects at the upper margin of the sphincter ani into the rectum. This condition of the base of the bladder not only obstructs the flow of urine, but is also the cause of the tenesmus to which he is frequently subject, though the rectum itself is at present free from the growth. The urine is normal, always clear, and free from blood or pus; but the increasing irritability of the bladder is the patient's constant torment. By night or day, he seldom passes an hour without being compelled to use his catheter; for, as soon as two or three ounces of urine collect, his bladder makes violent efforts to expel it. The wide extent of the induration of the prostate and floor of the bladder, and its irregular stony hardness, are the grounds on which we consider it to be a case, not of simple hypertrophied prostate, but of malignant, probably scirrhous, disease.

There is also at the present time, in Ward 9, a young man, whose life is tormented by cystitis and great irritability of the bladder, sometimes more, sometimes less acute, but of already more than twelve months' standing; and occasioned by a condition of the vesiculæ seminales which we believe to be tubercular. He has already undergone Syme's amputation at the ankle for strumous disease of that joint. On another occasion, I shall draw your attention to tubercular disease of this region, of which, from time to time, we get examples sent in as cases of stone. I will pass to the two cases of which the bladders are before you.

The first is the case of epithelial primary disease, whose history has been carefully recorded by Mr. A. J. Grant, the ward-clerk. The patient, No. 2448 in the hospital register, was sixty-three years old; and, until four months before his admission, had no sign of disorder of his urinary organs. The first symptom of his disease that attracted attention was hemorrhage. The urine became red and the blood increased so much that in a week's time it came away from the bladder in clots. Soon, but after the appearance of clots, pain began to be felt but only after the bladder was emptied. So long as the patient was still, and did not pass urine, he was free from pain. This character of the pains continued until after his admission to hospital; but, in a few days, there were added violent attacks of spasmodic effort to void urine, which, always painful, became excruciating towards the end of his life, growing more and more frequent, and at the end almost constant.

The frequency of micturition, at first not unusual for a man of his time of life —twice by night and about every four hours by day—steadily increased during the three months which elapsed after the first appearance of the blood, until the call to pass urine came every quarter of an hour. Up to this time, the urine, though bloody, was not offensive, and had no sticky deposit. At this stage of his malady, an irregular practitioner sounded the patient for stone. After this exploration of his bladder, which he described as being prolonged and very painful, his sufferings increased; micturition became necessary every quarter of an hour, and the urine, still loaded with blood, grew very offensive. Probably the exploration was the immediate cause of the cystitis, though this affection was almost certain to arrive sooner or later. Still, the danger of thus aggravating the patient's sufferings by instrumentation should always be kept carefully in view, when deliberating on the expediency of sounding a patient. On his admission, on December 7, 1880, he was found to be a fairly stout man, and in pretty good general condition; of this stoutness he lost little before death; but his state as to micturition was pretty much as already described; frequent (half-hourly) calls to pass urine—its ejection being accomplished with much straining and pain, the latter referred to the end of the penis; and blood and ropy pus passed every time with

the urine. The sound introduced into the bladder struck no stone, but caused great pain in passing over the neck; indeed, the exploration could not be completely carried out, owing to the pain it excited. The prostate was not enlarged, nor could any unusual condition of the bladder be detected by rectal examination. There were no enlarged glands to be felt in the inguinal or the iliac regions.

Thereafter, various remedies were employed to allay the cystitis and consequent irritation of the bladder, but without avail. On one occasion, the patient was anæsthetized, the bladder carefully sounded, and its ammoniacal ropy contents washed out by Clover's bottle. As before, no stone was found; but, in the purulent deposit from the fluid so exhausted, shreds of tissue were found on microscopical examination, by Mr. Stanley Boyd, our surgical registrar; these consisted of patches of epithelial and nucleated cells, to some of which a shred of fibres was attached. In spite of anodynes, of attempts by tying in India-rubber catheters, or by washing out with quinine or astringent solutions, or simple warm water, to diminish the accumulation of fetid urine, the patient's sufferings increased; the catheter could not be retained more than four or five hours; then the spasm it excited became unbearable. At this time constitutional disturbance began. His tongue became dry, and coated with brownish fur; and his strength rapidly diminished. In these circumstances, I proposed to him that he should submit to operation—not with any expectation of cure, but, by establishing a free drain for the urine as fast as it reached the bladder, of relieving him of the constant pain and straining excited by its accumulation and putrefaction therein. With this object, on December 29th, I performed the usual lateral operation for the removal of stone from the bladder, making at first a small opening in the neck of the bladder, through which I introduced my finger, and recognized a soft mass projecting from the floor on the right side. By enlarging the incision in the neck of the bladder, I was able to bring away, in a lithotomy forceps, the mass felt, which proved to be a pedunculated growth of cellular tissue, as large as a marble, but too much disorganized by sloughing for its structure to be minutely examined. By free injections of cold water, several such masses were washed out, along with much stinking pus and mucus. The hemorrhage during the operation was unimportant. The patient was but little relieved by the operation, though bleeding ceased and the urine drained away continuously through the wound. His spasms, though less frequent, continued with nearly the same severity until his death, on the third day after the operation.

Post-mortem, the condition of the urinary organs was very interesting, and especially so when compared with that of the case of villous disease, whose examination we made on the same afternoon. The bladder was contracted, of about six ounces' capacity, and, when laid open along the mesial line from the neck by the anterior part to the apex and everted, it revealed this condition. There is a growth, which, commencing on the inner surface opposite the pubes, continues along the right side to the apex, and there crosses to the left. On the right, the growth is much the thickest; while, on the left, its advancing margin is well defined, being raised near the apex a quarter of an inch above the general level of the mucous membrane. The surface of the growth is generally sloughy and very irregular; long shreds hang down from the upper portion, and from the right side depends a finger-like process, one inch long and a quarter of an inch across. The mucous membrane of the bladder elsewhere is gray and pigmented, thus showing considerable chronic inflammation. The walls are rugose, from moderate hypertrophy of the muscular tissue. Here are some sections of the growth, showing the nests of nucleated epithelial cells, occupying the meshes of a fine connective network, freely supplied with capillaries. You should compare it with the specimen from the villous growth, showing the delicate branching

processes hanging freely from the tumour. The ureters are but little, if at all, dilated, though, like the bladder, the mucous membrane and that of the pelvis, especially of the pelvis in the left kidney, are thickened, grayish, and marked with small hemorrhages. The kidneys themselves are congested and interstitially inflamed, the left particularly so. These changes in the kidney are of recent origin, set up by extension of the irritation from the bladder.

You will note that the condition of the body after death confirmed the indications of the symptoms during life, that the patient died of exhaustion consequent on the irritation of the bladder, and from the cachexia of the tumour. The general system was but to a small extent invaded. A few of the lumbar lymphatic glands were enlarged, and pale gray on section, but no consecutive multiplication of the growth beyond the bladder was found.

Next come the notes of the case of villous growth. J. M., 38 years old (No. 2615 in hospital register), a lamplighter, and, therefore, walking much daily, had been a healthy man, and noticed nothing unusual in his habit of passing urine until April, 1880, eight months before admission. Then suddenly his urine became red with blood after exercise, and flowed less freely than before. This red coloration was for some time only observed during and after exercise; never on rising from bed in the morning. The intermixture of blood continued, without intermission, to be the main trouble until last Christmas, with the exception only of three or four days, during which his urine was of ordinary aspect. About Christmas new symptoms appeared, namely, constant desire to micturate and uncontrollable dribbling. On Christmas day, clots of blood came away during the efforts to pass urine; at the same time pain commenced to be felt in passing urine, and, for three or four minutes afterwards, at the end of the penis. When admitted on December 30th, he walked to the hospital from Kentish Town, and the urine passed on his arrival was dull crimson. The next day the patient was passing urine and blood every few minutes, with much painful straining to void the last few drops; often black clots, without any urine, were then ejected. There were no renal or suprapubic tendencies; no swelling of the testes or cords. The prostate was of normal size, but the trigone of the bladder, felt through the rectum, appeared to be thickened though yielding. The finger experienced the kind of resistance afforded by a moderately distended bladder. To clear up this doubt, a flexible *coudé* catheter was passed into the bladder, encountering no difficulty, and giving rise to no pain in its passage; but, as only a few drops of blood escaped through it, some water was injected; this returned almost untinged with blood, being forcibly driven out both through and along the sides of the catheter. The bladder being thus proved to be empty, the catheter was withdrawn, and brought away in its eye a gray granulation. This was at once put under the microscope, when it was seen to be a compound papilla, covered by slender columnar epithelium. This discovery materially aided the diagnosis, otherwise difficult, of vascular tumour of the bladder. This diagnosis, suggested by the persistent painless hemorrhage, and by the fact that villous is the most frequent form of tumour of the bladder, was rendered certain by the structure of the papilla. This examination took place the day after the patient's admission, viz., December 31st. The treatment ordered was turpentine, in five-minim doses, every four hours, opiates to relieve spasm, rest in bed, and ice to the perineum. It was also determined that, if this did not check the hemorrhage in twenty-four hours, recourse should be had to subcutaneous injections of sclerotic acid, a form of the active principle of ergot. As the bleeding had not diminished by 11 A. M., on January 1st a subcutaneous injection was given, not of sclerotic acid, but of ergotine itself, specially prepared on a new method by Mr. Gerrard,

he hospital pharmacist. The injection was repeated at 5 P. M., and again at 1 A. M. on the next morning (January 2d). On each occasion half a grain was injected, about half the dose usually employed. By 11 A. M. the hemorrhage had greatly diminished, though not wholly ceased, when suddenly syncope set in, and he died. *Post-mortem* examination twenty-seven hours after death. The body was somewhat blanched, and the viscera were all more or less drained of blood. The heart contained a small quantity of fluid blood, free from clot, and was firmly contracted in rigor mortis. The pulmonary arteries were clear of coagula. Owing to the obscurity surrounding the cause of death, all the viscera were carefully examined, and were all found to be free from disease, with the exception of the urinary organs. These, from the great size of the growth, formed an admirable example of a villous tumour in the bladder; such tumours usually are not larger than a marble or small strawberry; but this, you see, is as large as a hen's egg, measuring over two inches in length, by one and a half inches in breadth. The growth itself is formed of long delicate villi of deep red colour, and attached by a short pedicle, measuring less than half an inch across, to the margin of the orifice of the right ureter, around which it so grows that a probe passed down the ureter reaches the bladder only after traversing the growth. These growths are scarcely ever, if ever, found away from the trigone, and usually spring from one of the three orifices. In structure they are true papillomata, almost warts; and they prove fatal, not by any malignant character of their growth, but mainly by their mechanical action, wearing the patient out with pain and irritation, and partly by exhaustive loss of blood, for the structure of the tumour is loose and highly vascular, each of these delicate papillæ being provided with its capillary vessel, so that the frequent rupture of bloodvessels is an unfailing occurrence. We owe to our surgical registrar, Mr. Stanley Boyd, the preparation of the specimens for our inspection, and also these beautiful sections of the growths under the microscope now before you. You will at once recognize the fine branching papillæ, each one containing its capillary, and covered by slender columnar epithelium, of which the mass is almost entirely composed.

The bladder, ureters, and kidneys are excellent examples of the changes which take place as simple results of impediment to escape of urine from the bladder. The bladder itself is of ordinary capacity, its mucous membrane is healthy, not chronically inflamed as in the example of epithelial cancer. It is rugose and slightly sacculated from the great hypertrophy of the muscular coats, being half an inch thick in some places. The ureters are vastly dilated on both sides, that from the right kidney almost admitting the little finger, and having its coats much thickened, but, like the enormously dilated pelvis and calyces, presenting no trace of inflammation, either recent or old. The kidney itself shows an extreme result of distension, being little more than a bag of fluid. All signs of papillæ or pyramids are gone, their sites at the heads of the calyces being occupied by depressions. The cortex forms a thin layer, nowhere more than a quarter of an inch thick, and with the expanded pelvis and calyces constructs the bag which the kidney has become. The left kidney in all respects resembles the right, except that the dilatation of its several parts is considerably less. The cortex is of ordinary thickness, pale yellow, and of normal consistence; and a good deal of the pyramids still remains. It is obvious how these changes come about. The growth began at the outlet of the right ureter, consequently impediment to the escape of urine from the right kidney commenced very early, and was kept up, long before any difficulty occurred to the entry into the bladder of urine from the left ureter; thus expansion of the left ureter and kidney began only when the tumour had gained such a bulk that would enable it to overlie the

orifice of the left ureter, when it fell on the floor of the bladder, or was com pressed against the trigone in the empty state of the viscus. So, again, th hypertrophy of the muscular coat of the bladder was caused by the impedimen to the discharge of urine when the tumour blocked the neck. This position o the tumour against the neck of the bladder probably excited the violent spasmod contractions which were so painful during the last days of the patient's life.

It is interesting to compare the absence of inflammation in this bladder wit the abundant evidence of cystitis, pyelitis, and nephritis in the case of epith lioma. There we have the slaty gray colour and punctiform hemorrhages in th mucous membranes, the shiny muco-pus adhering to the walls of the bladde ureter, and pelvis, and the nephritis most decided in the left kidney, and n quite absent in the right one. You will recollect, in the patient's account of h state previous to his admission here, that his urine, though bloody, was neith ropy nor offensive before the sounding by the quack; in fact, probably it wa very similar to that which our patient with villous tumour passed—dark red though fairly clear, and with a sediment consisting almost wholly of blood-clot After the sounding the urine quickly changed, and showed evidence of cystiti Cystitis being set up, it was not difficult, in a bladder deformed by thickening o its coats, for a shred of putrid muco-pus to slip into, or be driven into, the orifi of an ureter during some expulsive effort of the bladder, and there excite inflam mation, which would quickly travel along the irritated mucous surface to th pelvis of the kidney. This is one mode, though probably not the only one, b which pyelitis is set up in cystitis; but it is a mode that explains why, in case of cystitis and pyelitis set up by upwardly extending irritations, one ureter an kidney shall be affected while the other escapes.

In both these patients the sign that enabled us to make a correct diagnos during life was the evidence obtained by putting under the microscope fragmen of the tumour itself, these fragments coming away in the fluid withdrawn fro the bladder in the one case, and being brought out in the eye of the catheter i the other. But such good fortune is rare, and probably portions of the growt are separated only when it has attained considerable development. Hence i many cases the diagnosis (on which depends the treatment) has to be made o symptoms. Now the three leading symptoms of tumour are—1. Irritabl bladder; 2. Hemorrhage; 3. Pain of a particular kind. But these symptom also often accompany several other affections, namely, stricture of the urethra stone, chronic retention from enlarged prostate, malignant and tubercular diseas of the prostate and vesiculæ seminales, and certain diseases of the kidney; eve piles or ulcer of the rectum are occasional reflex causes of irritable bladder. Th presence or absence of such possible causes as these must be ascertained b physical examination of the parts. In these two cases the exclusion of all cause of vesical irritative hemorrhage and pain, but stone, was easy during life. The con dition of the urethra, and of the prostate and rectum, could be ascertained, whil the clinical symptoms, though not strongly indicative of stone, did not certainly contradict that disorder.

Irritability of the Bladder.—In cases of stone, stricture, and prostatic reten tion, it usually happens that too frequent and somewhat painful desire to pas urine is the first symptom for which relief is sought. When stone excites it, irritability is an early sign, because the cause of irritation, the stone, most fre quently lies on the neck, being continually thrown thither by the action of the vesical muscles. Cases of tumour commonly differ from the rest, in that bleeding is the first symptom to attract the attention. Irritability of the bladder is a late symptom. It did not appear in our two patients for some time (four weeks in

one man, and several months in the other) after hemorrhage had become habitual. The early or late variation in the time of the appearance of frequent calls to pass urine in cases of tumour when bleeding has become a prominent feature of their malady, depends much on the position of the growth; that is, in its proximity to the outlet from the bladder. In our case of epithelioma, the morbid growth began at the right side of the bladder, and, spreading in all directions along the mucous membrane, soon reached the neck. But in the case of villous tumour, the tumour was attached to the right ureter by a pedicle, and could affect the neck only when it had attained bulk sufficient to enable it to fall against that part. In the former, irritation soon came; in the latter, only shortly before death. Nevertheless, the character of the irritation they excited had features strongly unlike the irritability caused by calculus.

Hemorrhage.—The bleeding had characters differing from that customary with stone; it was the first symptom sufficiently urgent to attract attention; it was from the beginning comparatively copious, and soon consisted in great part of clotted blood. Again, the hemorrhage was persistent, and was almost throughout the leading symptom. This is very characteristic of tumour, though intervals of cessation of hemorrhage do occur during the course of a tumour. Even several weeks may at first intervene between the discharges of blood; no other symptom is developed, and the urine may remain in the intervals quite free from blood or albumen. But when once bleeding is set up, it becomes more and more copious, and the intervals between the bleedings grow more and more short, while the irritability is continuous, slight, or altogether absent. When a stone causes hemorrhage, it is seldom copious at first, and never prolonged; but it very rarely refrains from causing irritability.

Hemorrhage from calculus is caused by the stone eroding the mucous surface of the bladder where it lies, and opening a vessel whence blood escapes; but such vessels are commonly of small calibre, and are quickly closed by coagulation of the blood. Hence, characteristic of such bleedings, is the small quantity lost, being often sufficient merely to furnish traces of albumen in the urine, or to appear as a few drops of blood *per urethram* distinct from the urine. Copious intermittent hemorrhage may be caused by stone, but only in cases complicated by hypertrophied prostate, on which some dilated veins are coursing. Such veins often bleed when grazed by a stone, just as they will bleed copiously for a short time, even when there is no foreign body in the bladder, if the organ become congested by exposure to cold, by venereal excitement, etc. But, when the gorged vessels have drained themselves, and their orifices are plugged by coagula, the bleeding ceases until they are again over-distended, or again injured, and their coats give way anew. There is no regular increasing frequency and gravity of the hemorrhages. It is different with the bloodvessels of a rapidly enlarging tumour. They are very numerous, have but thin walls, and are ill-supported in the soft cellular tissue, in which the fibrous element is but scanty. In such new structures the vessels that first give way are plugged, and shrink, while new ones develop rapidly in their place, which are ruptured in a similar manner. Thus a continual escape of blood from the surface of the tumour is maintained for some considerable time.

Pain.—I have spoken of the *irritable bladder* and of *hemorrhage* as symptoms of tumour, and how, in their niceties, they vary from the peculiarities of irritability and hemorrhage set up by stone. The *pain* felt in these cases of vesical tumour closely resembles that due to stone, being felt at the end of the penis, sometimes elsewhere also; but the pain of stone is most acute immediately *after* the bladder is emptied. It is explained by supposing that the bladder's muscular contraction squeezes the stone against the ulcerated patch which it has worn for

itself, and that the pain subsides when enough urine has trickled into the bladder to expand its sensitive surface away from the stone. This explanation is probably a true one in many cases, but not in all. The character of the pain in our case of tumour was not exactly of this kind. It was caused by micturition, it is true; but during micturition it was most severe, and culminated in one or two agonizing spasms during the ejection of the last drops. It then began to subside, and soon disappeared, until the next act of micturition revived it. Hence the pain was one felt *during*, more than *after*, micturition. In the case of epithelioma there was ulceration of a great part of the surface of the bladder; in the other patient there was no ulceration, but there was a foreign body, the villous growth, which was embraced by the extrusor muscles of the neck of the bladder, and prevented their natural contraction. Both conditions accounted for the agonizing spasms. These differences in the symptoms were not sufficient to warrant the exclusion of stone as the cause of the patient's sufferings. But they were so far different as to suggest tumour rather than stone. This exclusion of stone was rendered more probable in the case of epithelioma, by failure to detect it with the sound. Sounding is useful to gain information respecting the condition of the bladder, beyond the proof it affords of the absence of stone. The presence even of villous growths sometimes may be felt by the sound, while, when no such growth can be found, the sound forms an useful landmark for the finger in the rectum when searching all that portion of the bladder which can be reached by that means. Sounding should certainly have been performed in the second patient when the loss of blood had been somewhat checked, and the patient's condition improved by opiates and rest. As it was, instrumentation in both cases obtained positive evidence for us, though in that of villous growth the sound was represented by a soft, flexible catheter.

To sum up, then, gentlemen, the remarks which I have made. The symptoms of tumour of the bladder resemble very closely those of stone; this, on reflection, we can see is only what we might expect on *à priori* grounds, for a tumour is, in all that concerns the functional activity of the bladder, as much a foreign body as a stone. The pain in tumour, though like that caused by stone, has its distinctions, which, though not very strong, are useful in diagnosis. It is due in some cases to ulceration; in some, to the efforts at expulsion brought about by grasping of the tumour by the extrusor muscles. Hemorrhage is in tumours an early symptom, and, once established, is the most constantly present; signs of irritation of the bladder are later on in their occurrence. With stone, the reverse holds good; bladder-irritation is an early and almost constant symptom, and hemorrhage, as a rule, is not copious, and is always markedly intermittent; in the cases where stone does produce copious bleeding, this proceeds from an enlarged prostate.

Exercise, perhaps, influences hemorrhage from stone more than bleeding from tumour; though it has a marked influence over the latter. But exercise is most provocative of pain to the calculous patient; witness the suffering caused by a ride in a jolting cart. On the other hand, exercise seldom causes pain to the patient with tumour. Sudden stoppage occurs with both classes of patients, though more frequently with the calculous ones. Owing to this want of broad distinction between the diseases, it will be proper in every case to sound the bladder, in order to gain all information possible respecting the state of the contents and of the neck and base of the bladder, and the structures in relation with it, by the sound and the finger.—*Brit. Med. Journal*, May 14, 1881.

Hospital Notes.

BELLEVUE HOSPITAL, NEW YORK.
(Service of Dr. AUSTIN FLINT, Sr.)
(Specially reported for the MEDICAL NEWS AND ABSTRACT.)

Diabetes Mellitus; Treatment with Codeia.

Peter S., æt. 35, Ireland, liquor dealer; admitted May 5th. In earlier life e patient's occupations were of a laborious nature, and led to frequent exposures d hardships. His later years have been spent in leisure. He has always ank malt liquors, in moderation, but never was addicted to the use of spirits til five or six months ago. Since then he has used them to excess, and often on an empty stomach. He had the initial lesion of syphilis twenty years ago, ich was promptly treated, and was not followed by secondary or tertiary mptoms. He has not indulged in excessive venery. He has not had malarial er, gout, or rheumatism. The patient enjoyed perfect health until about six nths ago, when he became very dissipated. He spent almost every night, for umber of consecutive months, in gaming and debauchery. He drank brandy ry often during the night, ate nothing, and, being absorbed with gaming, bitually retained his urine longer than was natural. He suffered from gastritis, h frequent vomiting. For four or five months he hardly took a substantial rishing meal. He cannot remember that he received any injury during this e, to his head or abdomen. Three months since he began to be debilitated d habitually constipated, having no fecal evacuations for eight or ten days at a e. One day, after having induced free catharsis with a saline purgative, he iced that his urine became suddenly abnormally abundant. He believes that passed several gallons daily. He suffered from urgent thirst. A month later appetite became voracious. He was obstinately constipated. He suffered m progressive asthenia, extinction of venereal desire, capricious appetite, ht febrile movement, and progressive emaciation, but did not take to the bed il his admission, on May 5th. He now complains of asthenia, but has no pain, staxis, œdema, or emesis. He has great thirst and an enormous appetite. His ne is pale, acid, sp. gr. 1036, and has no albumen nor casts. It contains thirteen ins of sugar to the ounce.

Treatment.—His diet was restricted to meats, milk, fish, eggs, cabbage and atoes, coffee, tea, and sherry wine. The only remedy employed in his case sisted of codeia, gr. ½, three times a day. On May 6th he passed 184 oz. of ne; on the 7th, 170 oz.; on the 8th, 135 oz.; on the 9th, 130 oz.; and on the h, 140 oz. [He left the Hospital a few days later to go to Europe. The improve-nt was progressive, although not marked, up to the time of his departure.—REP.]

—

Acute Articular Rheumatism; Treatment with Salicin.

William N., æt. 26, Ireland, clerk; admitted April 30, 1881. The patient es that he belongs to a healthy family, none of the members of which have r been afflicted with rheumatism. Five years ago, after exposure to inclem- weather, he was attacked with acute pain in his left ankle, with marked red- s and swelling of that joint. The inflammatory symptoms were subsequently y developed in the knees, hips, shoulders, elbows, and wrists. This attack fined the patient to his bed for two entire months, at the end of which time resumed his occupations, but suffered from constant dyspnœa, vertigo, epis- is, and cardiac palpitation. Two and a half years ago he had another attack acute articular rheumatism, which was milder, and incapacitated him for labour

only three weeks. The third attack occurred in March, 1881. He was admitted to Bellevue Hospital and treated during two weeks, with salicylate of soda. At the end of that time he was discharged quite cured, but returned on April 30th with acute inflammation in his knees and his left shoulder. His temperature was 101½°. His urine was normal. His heart was notably hypertrophied, the apex beat being in the 7th intercostal space. An organic systolic cardiac murmur was heard over the aortic orifice and was transmitted into the carotids. An endocardial systolic murmur was heard over the left ventricle, but was not transmitted.

Treatment.—Dr. Flint being of the opinion that endocarditis constitutes a contraindication to the employment of so powerful cardial depressants as salicylic acid or the salicylates, ordered salicin, grs. xx, to be administered every two hours, and sod. bicarb., grs. xxx. every three hours. On May 1st the urine had been rendered dististinctly alkaline. The temperature was 101°. The pain had not been relieved. On May 2d the temperature was 100¾°, and the pain had almost disappeared. On May 4th not a vestige of inflammation could be detected in the affected joints, and there was absolutely no pain. The cardiac murmurs persisted. The patient was allowed to sit up, and on the next day to walk about.

May 12. There is still some slight stiffness in the joints, which were the seat of the inflammatory symptoms. Aside from this the patient is quite well. The heart murmurs are still audible, although the endocardial murmur is very faint.

—

Insolation; Treatment by Cold Shower-Bath; Recovery.

THEODORE TURNBULL, M.D., of Monticello, Florida, reports the following case:—

C. A., æt. seven years, female, rather delicate, while returning from school on the afternoon of May 15, 1881, became suddenly unconscious and fell headlong to the ground. Her companions thinking her playing, deserted their little schoolmate, but afterwards observed their mistake, and then alarmed the neighbourhood; she was removed to the nearest house, which was only a few yards. When I arrived a few hours later, I found her in a comatose state; pulse quick and feeble; temperature in axilla 106.5°; respiration stertorous and somewhat accelerated; relaxation of sphincter ani; sighing and moaning sounds on expiration; no tracheal râles or convulsions; pupil neither contracted nor dilated, but not responding to light.

The treatment consisted of the wet-sheet method advised by Dr. Flint. The girl was stripped and placed in a sheet, water being sprinkled over the whole surface at intervals of half a minute; whiskey was given at short intervals, and in small doses to prevent vomiting. She began to rouse up in about ten minutes, the shower-bath being kept up for at least half an hour, at which time her pulse was soft and slow; temperature in axilla 100°. After being removed from the wet sheet, she was wiped dry and put to bed, ordered whiskey and carbonate of ammonia every hour.

May 16. Feeling comfortable, dismissed.

Cases of sunstroke are exceedingly rare in this section of the country, yet persons who have never spent the summer in Florida generally suspect that the profession is often called on to treat such cases. The non-occurrence of insolation is due, perhaps, to our delightful summer nights, which counteract the heat of the day, as it were, which are very much unlike the oppressive nights experienced by the residents of large cities. The day was intensely warm, yet the sun was hidden by clouds the greater part of the time, and, as we afterwards observed, these few hours of intense heat were the forerunner of a heavy rain and wind.

MONTHLY ABSTRACT.

Anatomy and Physiology.

The Reflex Relations between Lungs, Heart, and Bloodvessels.

The influence which the respiratory movements exert upon the blood-stream the lungs, heart, and bloodvessels is a subject which must always attract the ention of the physician and the physiologist. At first sight, it might appear t the problem was a simple mechanical one, explicable by physical laws; but e, as elsewhere within the body, it is necessary to take into account the vous apparatus and the influence it exerts directly or in a reflex manner in difying the action of the organs concerned. In considering the relation of the piratory movements to the heart, lungs, and great vessels, it has recently been practice to look, perhaps, too much to the subject as a physical problem, to exclusion of the nervous apparatus and its effects thereon. We consider, refore, that Dr. Julius Sommerbrodt of Breslau has done good service in ecting the attention of physicians and physiologists to the "reflex relations ween lungs, heart, and bloodvessels." Dr. Sommerbrodt shows that afferent ve-impulses proceed from the lungs, and modify by reflex action the activities the heart and bloodvessels in even a greater degree than is already known to he case.

The recent histological investigations on the nervous apparatus of the lungs in newt, frog, and other animals, by Egerow, W. Stirling, and Kandarazki, rd an anatomical basis in support of the physiological results. The results of e observers are conclusive that the lungs are supplied by a very large number nerve-fibres—medullated and non-medullated—in the course of which many ve-ganglia, as Remak showed, are intercalated. It is quite certain that all e nerve-fibres do not end in the non-striped muscle which exists in the bron- l wall and between the air-vesicles; but that many of them are afferent fibres, ch convey impressions from the lungs to the respiratory and cardiac centres, s to modify the activity of these centres by reflex agency. The present hing on this question is that, during inspiration, the intrathoracic pressure is ered, more blood flows from the veins into the right side of the heart, the od-stream in the lungs is affected, so that more blood passes into the left side he heart. Both these factors, as well as the increased number of heart-beats ing inspiration, increase the arterial blood-pressure during inspiration. During iration, the increased intrathoracic pressure causes a diminution of the supply lood to the right and left heart; and the decrease in the number of heart- ts during expiration—through stimulation of the terminations of the vagus in lungs—causes a fall in the arterial blood-pressure.

t has been attempted to show the influence of respiration on the circulation by ygmographic investigations. In these investigations during normal breathing, increase of the heart beats during inspiration, and the decrease during expira- , is scarcely perceptible, but occurs very markedly during forced respiration, when the respiratory movements are interfered with (Marey). It would seem t all the phenomena of the influence of the respiration on the circulation are plicable on mechanical grounds, except the changes in the number of heart- ts, which are of a nervous nature. The first proof of a reflex relation between lungs and the heart was given by Hering, who showed that moderate inflation

(30 to 35 millimetres of mercury) of the lungs in dogs caused an increase in the number of heart-beats. The first effect was always a fall of the blood-pressure; the second, an increase in the number of heart-beats, and that to the extent of double or treble the number of beats before the experiment. As soon as the inflation of the lungs was interrupted, the acceleration disappeared. Hering came to the conclusion that the afferent nerve-fibres of the lung bear the same relation to the inhibitory cardiac centre in the medulla that the depressor nerve bears to the vaso-motor centre. Both centres appear to be in a state of excitation, which is diminished by stimulation of certain afferent nerve-fibres.

There can be no doubt that one might expect to find a similar relation between the lungs and heart in man. Dr. Sommerbrodt has analyzed more than one thousand sphygmograms of the radial artery, especially during the performance of Valsalva's experiment, and during the inhalation of compressed air. During Valsalva's experiment, three marked changes occur in the sphymographic curve: 1. When the expiration with closed glottis begins, the sphygmogram rises above the abscissa, then falls slightly, and rises again before the end of the experiment; 2. During the experiment, and for a few pulse-beats thereafter, the individual pulse-beats become dicrotic; 3. The heart-beats are accelerated during the experiment, and for a few beats after free respiration. The rapidity of the rise in the sphygmographic curve depends on the rapidity, force, and duration of the expiration. The dicrotic or hyperdicrotic condition of the pulse-beats is always present, and is the most important sign of a diminished tension of the arterial wall and a fall of blood-pressure. The acceleration of the pulse-beat is always most marked in the latter half of the experiment, and the increase may reach 75 per cent. of the original number of beats.

With regard to inhalation of compressed air, its effects are twofold: first, purely mechanical; and, second, a reflex nervous action. The mechanical effects —apart from the ventilation of the lung and the gymnastics of the lung—are these. After a minimal increase, the blood-pressure in the aorta is much diminished, venous blood accumulates in the extrathoracic veins, the lesser circulation is thereby relieved, and the arteries become emptier. The reflex nervous effects are shown in the acceleration of the heart-beats, the diminution of the tension in the arterial wall, and the fall of the blood-pressure. Whilst the inspiration of compressed air is itself a hindrance to the circulation, its further effects exert a favourable influence on the circulation by accelerating the blood-stream. In cases of lesion of the valves of the heart, all of which hinder the circulation, inhalation of compressed air, as it favours the circulation, must be useful; and both Waldenburg and Sommerbrodt speak very strongly of its therapeutic effects in certain cases of valvular lesion of the heart.—*British Med. Journal*, June 25, 1881.

—

Nerve-plexuses of the Extremities.

Professors FERRIER and GERALD YEO have recently contributed a valuable monograph on this subject to the *Proceedings of the Royal Society*. They prove that a plexus has a great functional significance, and does not merely represent a convenient arrangement for the distribution of nerves to individual muscles. They rightly insist on the determination of the effects of excitation or destruction of the individual roots of a plexus, as being the only possible method by which we can discriminate between the sensory and motor constituents of the nerve-trunks, or indicate their functional relations and distribution. In order to throw light on these questions by physiological researches which may be regarded as almost directly applicable to man, these physiologists have made a series of experiments on the motor roots of the brachial and lumbo-sacral plexuses. Excepting in the

absence of a branch to join the phrenic nerve, the brachial plexus is essentially the same in the higher quadrumana as in our own species. Reckoning the first lumbar as a thirteenth dorsal vertebra, and counting the last lumbar as a first sacral, then numbering the nerves in harmony with this arrangement, it is found that, in the old-world monkeys, the mode of distribution of the lumbar and sacral plexuses is the same as in man. In observing the effects of stimulation of exposed motor roots, after numerous precautions, attention was directed more especially to the resultant muscular combination, rather than to the mere number of muscles thrown into action; since the actions thus excited are all complex co-ordinated movements of great significance. It was found very difficult, when so many events are occurring simultaneously, to analyze each muscular combination into the individual factors at work; and, on that account, the muscles stated to be in action when any one particular root was stimulated, were only definitely registered as being thrown into action, under such a condition, after repeated observations, the suspected muscles being partially exposed when it was found difficult to be otherwise sure of their co-operation.

The movements resulting from stimulation of the individual roots of the brachial, lumbar, and sacral plexuses, appear to represent a highly co-ordinated functional synergy, and not mere contraction, more or less strong, of a given number of muscles, although many muscles are excited to contraction by more than one root, as previous observers have already discovered. The muscles thrown into action by irritation of each root being innervated, in most cases, by several nerve-trunks, it would appear that the plexuses which contiguous roots form with each other, serve to distribute the requisite motor fibres in different trunks to the various muscles engaged in each functional combination. Section of any motor root was found to paralyze, not the individual muscles involved, but their power of combination.

Irritation of the eighth cervical root, for example, caused firm closure of the fist, pronation and flexion of the wrist, extension of the forearm, and retraction of the upper arm; an action precisely imitated by pulling some object, hanging in front, downwards and towards the hip. Stimulation of the seventh cervical produced invariably a complex action, which brought the back of the hand against the nates. On irritation of the fifth lumber (the fourth in man), the lower extremity was straightened directly backwards, in the position which immediately precedes the lifting of the foot to take another step forward in the act of walking. Although division of the roots above mentioned involved complete loss of voluntary exercise of the given combinations, it was found not to cause paralysis of the individual muscles contributing to each combination. This is what was to be expected, since many of these muscles are innervated by more than one root, and hence, though weakened, they might still act in other combinations in so far as they were supplied by other roots. Panizza has gone so far as to believe, from experiment, that there is no absolute immobility of a limb until every root is cut.

In conclusion, these experiments tend to show that the cervical and lumbar enlargements of the spinal cord are centres of these highly co-ordinated muscular combinations. We understand that important work, to elucidate this question, is at present being carried on by the same physiologists—work that may bear fruit of great physiological and pathological value.—*British Med. Journal*, June 25, 1881.

Physiology and Pathology of the Excretion of Urea.

In a prize essay on the Physiology and Pathology of the Excretion of Urea, Dr. H. Oppenheim (Pflüger's *Archiv*, B. xxiii. p. 446) endeavours to ascertain

the effects of food upon urea excretion. The observations detailed in this important paper were chiefly made upon the author himself, after the following manner. He was at pains to bring himself into such a condition that the quantity of urea excreted in the twenty-four hours remained nearly constant, and the urine and feces contained as much nitrogen as reached the body in the form of aliment. The urea-estimations were performed according to Liebig's method; and he believes that the results were free from the sources of error which, according to Pflüger, may occur in such analysis. During the first seven days, the quantity of urea excreted varied from 32 to 35 grammes in the twenty-four hours. The average hourly excretion of urea was 1.42 grammes. In the night (that is, in the hours after an albuminous meal) it stood at 0.13 gramme per hour over the average. The urea left the body in a solution which was never near saturation, but there was a distinct relation betwen the water and the urea excreted; so that, other things being equal, when the quantity of water passed was greater, the quantity of urea which it contained was also increased. The taking of coffee, while producing diuresis, caused a diminution in the quantity of urea, but along with this there was an increase in nitrogenous elimination by the bowel. Quinine caused an increase of the elimination of urea in the twenty-four hours to the extent of 4 grammes. This action began soon after taking the dose (2 grammes), and lasted for about twenty-four hours. The use of pilocarpin showed that the artificial production of great perspiration and salivation did not bring about any remarkable elimination of nitrogenous material from the body.—*London Med. Record*, June 15, 1881.

Materia Medica and Therapeutics.

Barium in Mineral Springs.

Dr. NEALE (*London Med. Record*), referring to the fact of the existence of barium in natural waters, says that we are not inclined to attach much importance to the presence of small quantities of barium in the Harrowgate waters, for several reasons; first, because their action (supposing it were to be considerable) must be greatly interfered with, when burdened with the presence of the large quantity of other salts. Next, the chloride of barium has been at times very extensively used, and in large doses; for instance, Hufeland used to give 4 to 5 grains of the crystallized chloride three or four times daily; and Lisfranc began with 6 and went on to 12 grains every hour, and at last gave 48 grains in one dose. Similar instances could be quoted, but we have said enough to show that probably the very small doses have not much operation. Further, chloride of barium and chloride of calcium had both fair trials, chiefly in glandular and scrofulous cases, but were both practically given up. Their effects were considered to be very similar, and some in those days thought that the calcium was more powerful than the barium. This, however, seems certainly not to be the case. Dr. Wimmer has called attention to the share which chloride of calcium may have in the operation of the Kreuznach and some other waters. We would venture to suggest that, as that salt is present in the Harrowgate waters in at least fifteen times the quantity of barium, it would be well worth Dr. Oliver's while to take up the consideration of the operation of a substance which occurs in so very tangible a quantity that its action must in all probability be stronger than that of the barium (*vide* Dr. G. Oliver's paper in the *Practitioner* for May, 1881, on "Barium in Medicinal Springs, with Special Reference to the Presence of it in some of the Harrowgate Waters").

Bromide of Ammonium in Whooping-cough.

As the result of five recently observed cases, KORMANN (*Jahr. für Kinder.*, Heft 1 and 2, 1880) asserts unhesitatingly that bromide of ammonium is more useful in whooping-cough than quinine. The bromide acts with greater certainty, and after a few doses (for young children, 5 centigrammes ($\frac{1}{4}$ grain), for older children, from 25 centigrammes (4 grains), to 40 centigrammes (6 grains) every two hours) a marked improvement is observable. Should it be rejected by coughing, it must be repeated. There is only one contraindication to its use; and that is, when there is in addition chronic bronchial catarrh. The author was much struck by the wonderful efficacy of the bromide in whooping-cough, and is at a loss to understand the prejudice against it. In only a few cases was there marked drowsiness, and this was quickly overcome by suspending the remedy for a few hours. When the medicine is not retained, it should be abandoned, and tannic acid or quinine substituted, or an attempt might be made to give it in a syrup, or with liquorice. —*London Med. Record*, May 15, 1881.

—

The Action of Aconitine in Neuralgia.

M. DUMAS of Cette has been studying the action of aconitine in facial neuralgia, and comes to the following conclusions (*Journ. de Thérap.*). Crystallized aconitine is a powerful medicine. Very efficacious, especially in congestive facial neuralgia, and in some other forms of neuralgia *à frigore*, it is useful in the majority of catarrhal affections, in which it may replace the various preparations of aconitine. It deserves to be preferred over the other kinds of aconitine, which are ill-defined and unequal in their action. It is but slightly efficacious in tic-douloureux of the face, in which it only produces temporary sedative effects. As with the other alkaloids, it is tolerated when it is methodically administered. It may be long continued, without fear of the effects of an accumulation in the organism. It should be commenced in small doses and progressively increased. Unless in cases of tic-douloureux, the average dose should be restricted to two milligrammes daily. Carefully prepared granules containing a quarter of a milligramme (.0038 grain) of the alkaloid, or half a milligramme (.0077 grain) of the nitrate, deserve preference.—*London Med. Record*, June 5, 1881.

—

Aconite in Remittent Fever.

Dr. BOMFORD (*Practitioner*, March, 1881) records three cases of remittent fever treated with aconite. In its general course and uncertain duration, remittent fever somewhat resembles acute rheumatism, and especially on the West Coast of India is not uncommonly accompanied by slight inflammation of the joints. In the first of Dr. Bomford's cases, the patient, an officer, aged 20, had for four days been treated with large doses of quinine, but without effect. there being a daily exacerbation of fever at 3 P. M. On the fifth day the symptoms had increased in severity; the patient was sleepless, his tongue dry and glazed, skin dry, temperature in the axilla 103 deg., and pulse 88. The quinine was discontinued, and he was given one minim of tincture of aconite at 3 P. M., the dose being repeated every quarter of an hour until 4.30; it was given again at 5, and then every hour until 9. On the following day he was much better; he had slept well, his tongue was moist, the appetite was returning, the temperature was 100.4 deg., and the pulse 82. The tincture of aconite was again given in minim doses at 10.30 and 11 A. M., and then every hour until 7 P. M. At 3 P. M. there was free perspiration, temperature 99.5 deg., pulse 66. At 9 P. M., 97.5 deg., pulse 62. He had no relapse, and a week later returned to duty. The

other cases are similar and equally striking. The author considers that the good effects of aconite in this class of fevers may be summed up as follows: 1. It reduces the temperature. 2. It reduces the rapidity of the pulse, and makes it full and strong. 3. It cleans the tongue, and restores the digestive functions. 4. It induces sleep. 5. It increases the quantity of the urine, and seems to have a direct effect in removing the symptomatic congestion of the kidneys. 6. It promotes perspiration. Dr. Bomford has often given aconite, sometimes for days together, to typhoid cases to clean the tongue and induce sleep. If pushed, it will reduce the temperature, but only slightly. The fall of temperature is not always accompanied by profuse sweating, and cannot be explained on the "heat-loss" theory as being merely the result of evaporation of the sweat. There can be no doubt that aconite acts best when given in frequent small doses.

Dr. William Murrell, of London, in commenting upon the above communication in the *London Medical Record*, makes the following practical remarks in regard to the administration of aconite in fever: "The author is quite right; aconite does act best in small doses, frequently repeated. Many practitioners get no good from aconite because they do not know how to use it. The dose of the tincture recommended in the *British Pharmacopœia*—from 5 to 15 minims—is absurdly large, and no one with any respect for his patient's safety or his own reputation would ever think of giving it. The best way is to put half a drachm of the tincture in a four-ounce bottle of water, and to tell the patient to take a teaspoonful of this every ten minutes for the first hour, and after this hourly for some hours. Even smaller doses may be given in the case of children. The great indication for the use of aconite is elevation of temperature; the clinical thermometer and aconite bottle should go hand-in-hand. If properly used, aconite is one of the most valuable and indispensable drugs in the *Pharmacopœia*."

—

The Arsenical Treatment of Chorea.

Arsenious acid is strongly recommended by Dr. SAWYER (*Brit. Med. Journ.*, Dec. 18, 1880) as being by far the best remedy for chronic chorea; and it is pointed out that the dose of liquor arsenicalis, as laid down in text-books, is too small. The quantity given should be cautiously increased. One exceptional case is mentioned, in which the dose was experimentally increased until as much as a drachm of Fowler's solution was given thrice daily, apparently with good effect on the chorea, until signs of gastro-intestinal irritation were produced.—*London Med. Record*, June 15, 1881.

—

Atropia in Vaseline.

Dr. KLEIN, of Vienna, recommends, in place of the ordinary solutions of atropin, to use an ointment prepared as follows: Sulphate of atropia, ½ gr.; vaseline, 160 gr. If the atropin salt be thoroughly triturated with the vaseline, it is unnecessary to use any solvent. The application of this ointment is much easier than the instillation of the solution. It is best applied by means of a camel's-hair brush to the inner surface of the lower eyelid pulled down.—*London Med. Record*, June 15, 1881.

—

Atropia as a more Effectual Remedy than Extract of Ergot in Menorrhagia and Hemoptysis.

TACKE (*Berl. Klin. Wochen.*, No. 6, 1881), having injected sulphate of atropia subcutaneously for eczema in a female patient ($\frac{1}{100}$ grain twice daily in distilled water for two days), noticed that the menses, which had been very profuse, became moderate, and remained so. The same result he has seen follow five

times in two other patients, and in a case of hemorrhage from the lungs the hemorrhage twice ceased immediately on the injection. He holds that as a remedy for visceral hemorrhage it is preferable to extract of ergot: 1st, on account of its certainty, and 2d, because, in the strength used by him (about ⅛ grain to an ounce of distilled water), it does not cause the inflammation which almost invariably follows the subcutaneous injection of extract of ergot.—*Lond. Med. Record*, April 15, 1881.

—

Administration of Cod-liver Oil.

Mr. FAIRTHORNE (*Pharmaceutical Journal*) suggests a new method of taking cod-liver oil, which consists of adding two drachms of tomato or walnut "catsup" (according to a new contemporary, the accurate and most appropriate orthography), to each ounce of the oil, the mixture being shaken before taken. He very pertinently remarks that taking an ordinary emulsion of cod-liver oil is like eating cod-fish or lobster with a dressing of sugar and gum. He has found the mixture of catsup and cod-liver oil to agree with many persons much better than in any other form in which cod-liver oil had been taken, and this he attributes to the association of substances generally employed as additions to food bringing into operation those digestive faculties of the stomach which might otherwise remain dormant when such incongruous substances as sugar, and one of the principal ingredients of fish, are introduced together into the stomach. Some years ago a paper was published in one of the scientific journals, showing that the condiments usually employed with particular kinds of food were the most appropriate ones, since they developed an electrical current, a phenomenon which did not appear to be indicated by the galvanometer when what would be considered by epicures to be incongruous articles of food were experimented with. Possibly the action of different adjuncts to food on the nervous system, and through it on the digestion, may deserve more attention than is generally devoted to that subject. Mr. Fairthorne also states that the following mixture is readily taken by the patient: Liebig's extract, ½ ounce; extract of celery seed, ½ fluidrachm; vinegar, 1 fluidounce; water, 2 fluidounces; cod-liver oil, 5 ounces. The extract of beef is dissolved in the water, the vinegar and oil are added, and the whole shaken with the extract of celery.—*British Med. Journal*, April 2, 1881.

—

Tetanus treated by Calabar Bean.

The case of a boy, aged 11, is related in the *Lancet*, Jan. 29, 1881. Tetanus followed a lacerated wound of the heel. Chloral and belladonna in full doses were first tried, but the patient became worse, and was presently unable to swallow his medicine, convulsive attacks being brought on by each attempt. Subcutaneous injections of morphia also caused convulsions and did no good. Gelatine lamels, containing one-sixtieth of a grain of extract of Calabar bean in each, were next obtained. One was given every four hours, being slipped between the teeth and allowed gradually to dissolve in the mouth. Improvement was noted two days later. The lamels were continued for seven days, by which time the boy was convalescing satisfactorily. He has since completely recovered. The case was an extremely unfavourable one at the time when the administration of Calabar bean was commenced. The boy's age, and his ability to take plenty of nourishment throughout his illness, were of course greatly in his favour, but the result affords a fair presumption that the drug had a beneficial effect. It, therefore, deserves a further trial (in the form of gelatine lamels) in similar cases.—*Lond. Med. Record*, June 15, 1881.

Resorcin in the Treatment of Cholera Infantum.

Andeer, of Würzburg, having asserted that resorcin ($C_6H_4(OH)_2$) has a marked antifermentative and antiputrefactive action, Dr. TOTENHÖFER, of Breslau, was induced to try it in an epidemic of cholera infantum during the summer of 1880 (*Breslauer ärztl. Zeitschr.*, 1880, No. 24). Of 91 children treated as out-patients in this way, there died 17. Of these last, three died from complications (pneumonia, croup, and meningitis); deducting these, the mortality was 15.4 per cent., against 34.4 and 30.7 per cent., the two previous years. The writer attributes the following actions to resorcin: 1. The vomiting ceases. 2. Symptoms of collapse are neither caused nor increased. 3. The number of stools is diminished. 4. Resorcin is not so irritant as carbolic acid, but quite as antimycotic. 5. It is readily taken without any corrigent, and is well borne. 6. It brings about rapid absorptive action in the stomach and intestine. Andeer gives adults internally a solution of 15 to 30 grains in 3½ ounces of water; and in accordance with this the drug was administered to children during the first months of life, in a solution of 1½ to 5 grains in 2 ounces of infusion of chamomile. Soltmann, in whose clinic the treatment was carried out, gives subcutaneous injections of ether when collapse is present, before commencing the resorcin treatment; in cases of peritoneal irritation after removal of collapse, resorcin with one to three drops of tincture of opium.—*London Med. Record*, June 15, 1881.

—

Tannate of Quinia in Whooping-Cough.

In 1867 BINZ (*Berl. Klin. Woch.*, No. 9, 1881) was induced on theoretical grounds to employ quinine in the convulsive cough of children, other drugs having frequently failed in his hands to give relief. He found it most effectual in alleviating the violence and duration of the paroxysms of whooping-cough. The attacks became less frequent and less severe, and the vomiting ceased. When quinine was given quite at the commencement of the illness, the spasmodic element was suppressed, and the attack assumed the form of a severe, though manageable bronchitis. To obtain these good results, it is necessary to give the remedy with no sparing hand. Twice a day the patient must take as many decigrammes as he is years old (a decigramme is a grain and a half), so that a child four years old would require 6 grains at a dose; at ten years of age he would want 15 grains; at fourteen, 21 grains, and so on.

The treatment must be steadily persevered in, for no immediate effect is observed. As a rule, there is no improvement until the patient has taken the full dose for three or four days, but then the progress is rapid. These results have been confirmed by one of Binz's pupils, JANSEN (*Klin. Beiträge zur Erkenntniss und Heilung des Keuchhustens*, 1868), and by HAGENBACH (*Correspondenz für Schweizer Aertz.*, 1881, and GERHARDT'S *Handbuch der Kinderkrankheiten*, 1877), who, as director of the Children's Hospital at Basel, has had many opportunities of investigating the subject. Hagenbach considers that, in the treatment of convulsive cough, quinine must be awarded the foremost place. The difficulties—at times insuperable—of inducing children to take such a bitter medicine as quinine, have been overcome by using the tasteless tannate of quinine. During a severe epidemic of whooping-cough in the neighbourhood of Rheindorf, Dr. Becker used this preparation with the greatest success. Hagenbach, in corroborating Becker's statements, says that it is best to give the tannate of quinine as early as possible, the dose being twice a day as many decigrammes as the child is years old. In his experience, the attacks have in a few days considerably

abated, and the vomiting has ceased. He also used it with considerable success in the ordinary catarrhal affections of children. It is best given in a little sugar and water. In only one case did it induce constipation, whilst, in another, it arrested an attack of diarrhœa. Unfortunately, tannate of quinine is a very uncertain preparation, containing at one time 10 per cent., and at another 25 per cent., of the alkaloid. On this account it is a good plan to use the neutral tannate of quinine, made by precipitating the alkaloid with tannate of ammonia. The great objection to the employment of these salts is their expense, but there is good reason to suppose that they will soon be obtained by a new chemical method at a more reasonable rate.

It would appear that quinine produces its beneficial effects by a specific action on the organism which causes whooping-cough; salicylic acid and carbolic acid acting in the same way. Chloral-hydrate probably acts by lessening reflex action, and we know that its effects on the spinal cord are so marked that it is used as an antidote in cases of strychnia poisoning. The great objection to chloral in whooping-cough is, that it soon loses its effect unless the dose be increased. With quinine this is not the case; and, although it acts slowly, it is certain. It exerts no direct action on the nerves, but gradually destroys the poison itself. No hesitation need be felt in increasing the dose of tannate of quinine if necessary.—*London Med. Record*, May 15, 1881.

—

Use of Thymol in Burns.

Dr. FULLER, of Neukirchen, a mining district in which burns caused by explosions or fire damp or powder are frequent, has adopted a mode of treatment of burns by thymol, which he has found attended by most favourable results (*Hom. Rundschau* and *Therapeutic Gazette*). Each patient, as soon as admitted to the hospital, receives a warm bath. The burnt surface and its surroundings are then washed with an aqueous solution of thymol (1 to 1000), followed by the application of thymol spray for several minutes. The blisters are not disturbed, but are handled with extreme care. The raw surface is then painted with a one per cent. thymolized linseed oil. The patient is then laid on a waterproof mattress, the temperature of the room being kept comfortably warm. Particles of coal or other foreign matter, if not too minute, are, as a matter of course, at once removed. It is often very difficult to so lay the patient that the burned places are relieved of pressure, and it is frequently necessary to allow him to remain in a sitting posture, sometimes for several days, with support for the chin, or even *a la vache*, by suspending him by means of wide strips of muslin, passing under the chest or abdomen—the strips being fastened above. The application of thymol should at first be repeated every ten minutes; and as it relieves pain very remarkably, the patients themselves call for it. For this purpose large soft-haired paint-brushes are used. At first the oil is absorbed somewhat rapidly, and as soon as this has occurred a sensation of intense burning follows. The applications are gradually made less frequently; as an indication of their necessity, the appearance of the skin is sufficient. As soon as the oil is entirely absorbed, it should be replaced by a fresh portion, as it is important to prevent contact with the air. During the first few days the thymol spray is also applied as often as possible, which does much toward alleviating the pain.—*Lond. Med. Record*, June 15, 1881.

Medicine.

The Nature of the Infecting Agent in Diphtheria.

In an unusually interesting paper in the *British Medical Journal* for July 2, 1881, Dr. MICHAEL W. TAYLOR, of Penrith, discusses the Fungoid Origin of Diphtheria, especially as shown in an isolated outbreak in which dampness appeared to act as a favouring cause. In regard to the special agent he offers the following solution of the question:—

"The results of the investigations of scientific pathologists, during the last fifteen years, all tend to further the broad theory, that 'all contagia are probably particulate,' and that the infective particles enjoy endowments not known to exist otherwise than in association with life and organization; and, moreover, microscopy and experimental inoculation have incontestably demonstrated the presence of distinct specific vegetative forms in the contagious liquids of at least four contagious diseases. These are smallpox, sheep-pox, splenic fever, and relapsing fever. It has been shown—first, that the minute organisms discovered infiltrating the tissues and blood in these diseases, which have been described, according to their form and structure, as the micrococcus, bacillus, spirilla, etc., are not congeneric with the animal body in which they are found, but are apparently of the lowest vegetable kind; and, secondly, that they constitute the essence, or an inseparable part of the essence, of the contagia of these diseases.

"It has been proved, so late as the present year, by Toussaint, of Toulouse, that the very infectious disease amongst poultry, called the *cholera des poules*, consists of a minute bacterium, which is capable of cultivation out of the body, in chicken-broth; and it has been long known that the epizöotic parasite which infests the silk-worm, and the house-fly, is a mould with fungal threads and mycelium, which is almost identical with oïdium, or peronospora, so well known in connection with the potato and vine plagues.

"Thus we see that the progress of modern research justifies the conclusion, that the vastly multiplied minute organisms and vegetable sporules, inducing and produced by the ordinary processes of fermentation and putrefaction going on in nature, may be absorbed into the blood of animals, or be engrafted on their tissues, so as to assume an intimate relationship with many of the diseases most fatal to human life. Hence there is really nothing startling nor singular in the proposition I enunciate, that the diphtheria in this particular instance had its origin in some of the fungoid sporules which infested this chamber.

"In the year 1858, Professor Laycock, of Edinburgh, put forth the theory, that diphtheritic exudation depended on 'oïdium albicans,' or potato fungus;[1] the same conjecture was supported by Dr. Wilks and others;[2] long before which—in 1844—Gruby, of Paris, and afterwards Ch. Robin, had shown, by the microscope, that in the pseudo-diphtherite, or muguet, and in thrush, the buccal pellicles displayed the tubular filaments and mycelium of a vegetable form analogous to the oïdium. This hypothesis, however, in regard to true diphtheria did not receive acceptation, in consequence of the general failure at that time of sufficient microscopic evidence, in the false membrane itself, of the presence of vegetable growths.[3] The more recent researches, however, of Nassiloff and

[1] Lancet, 1858. Laycock, Lecture on Diphtheria.

[2] Medical Times and Gazette, vol. xxxviii. On Diphtheria and its connection with a Parasitic Vegetable Fungus.

[3] Since I have been engaged with this paper, I find from a communication kindly forwarded by the Rev. John E. Vize, M.A., Forden Vicarage, and published in 1880, that this able fungologist has strongly maintained the dependence of diphtheria on an oïdium.

Oertel in Germany, Leloir in France, Burdon Sanderson, and other workers in scientific pathology, show that pharyngeal diphtheria is a true mycosis, or infiltration of living tissue with micrococci, and that the development of these minute spheroids is intimately associated with the morbid process. It has been found that the pseudo-membrane consists of layers of stratified epithelium, more or less mingled with products of exudation from blood-plasma and some micrococci, but that, in the mucous and submucous tissues, the channels communicating with the lymphatics are filled with granular matter, which is mainly micrococci, or masses of vegetation; so that observation has tended to establish a certain analogy in the morbid processes of diphtheria with those in the respective diseases I have mentioned—splenic fever, or woolsorters' disease, for example, which we know to be produced by vegetable sporules existing outside of the body.

"As was well shown by Sir James Paget, in his masterly address at the Cambridge meeting of the Association, some of the obscure processes of human pathology are capable of receiving much elucidation from a comparative study of diseases in plants, and of the action of parasites on the vegetable kingdom. We have described to us, by the practical mycologist, an infinite multitude of distinct structural forms of fungi, each of which has its own habitat, and affects certain sites of decaying vegetable or animal matters, or preys on certain living species or natural orders of plants; each has its own feeding ground. We cannot advance far in this study without being struck with the marked parallelism which exists between the action of the parasitic spore in producing local and general morbid changes in the plant, and the action of a bacillus, or oïdium, affecting animal tissues. The resting-spore, let us say, of the peronospora infestans, capable of resisting the hardest winter frosts, and the greatest heats of summer, lies dormant underneath the ground, until the time of germination arrives; its habitat, or feeding-ground, is the potato; at the proper season it meets with a tuber; it attaches itself to the skin by its little lash-like appendage; it germinates there; it starts out its rootlets into the parenchyma of the tuber—this is its mycelium; it branches and penetrates in all directions; it poisons the tissues; the plant looks sickly; the stalk withers, and the leaves blacken; it has fulfilled its end, the reproduction of its kind. So, when the leaves of phanerogamous plants are attacked, the zöospores of the fungus gain entrance by the stomata, throw out their mycelium through the cellular tissue of the leaf; the thread-like filaments burrow underneath in search of food; whilst the epidermis is raised like a blister, and perishes and exfoliates, just as does the epithelial false membrane from a diphtheritic throat. No theory in regard to the essential cause of diphtheria explains so well many known facts in its history as that of its fungoid origin. For example, the persistence of vitality in the so-called resting-spores of fungi lying dormant in drains, or amid heaps of putrescible matter, for an indefinite time after an outbreak, affords a ready explanation why the disease so often inveterately clings to certain dwellings and localities."

—

Hay Fever.

M. DE BUDBERG, in a communication to the Société Vaudoise de Médecine, calls attention to the value of the method of treatment devised by Helmholtz, which is less widely known than it should be. The first case was observed by M. de Budberg in an Englishwoman, who had suffered from it for twenty years. The treatment employed consisted of nasal irrigations of solution of quinine, recommended by Helmholtz (1 part in 750 of water). This irrigation brought away masses of brownish mucus, in which were found small round yellow corpuscles, of smaller dimensions than the blood-corpuscles. It did not contain either vibrios or bacteria. After two or three douches, the patient was perfectly well. The

attack was arrested from that time. A solution of chlorate of potash was employed, and no relapse occurred, although the patient frequently passed flowering meadows. Every time that she attempted to suspend the treatment, a relapse occurred, which, however, was promptly ameliorated by the use of the douche. M. de Budberg thinks that the yellow corpuscles found in the nasal mucus of this lady were pollen-corpuscles. The nasal douche freed the mucous membrane from them; hence its curative effect. In cases in which the mucus contained bacteria, Helmholtz's solution of quinine would probably be indispensable. In all cases, it is necessary that the douche should be made most carefully, so as to entirely wash out the whole of the nasal mucous membrane. Dr. Blackley, in his excellent monograph, relates that he induced hay fever in his own person by the introduction, on the nasal mucous membrane, of various kinds of pollen. He cites more than sixty different kinds of them—as a rule, graminaceous pollens.—*British Med. Journal*, July 2, 1881.

—

Treatment of Enteric Fever by Prolonged Lukewarm Baths.

For many years the reduction of the pyrexia of fevers by cold or lukewarm baths has been the subject of careful and extended inquiry both in this country and in Germany. Among those who have done much useful work in the investigation are Brand, Ziemssen, and Riess, while Dr. Wilson Fox's accurate and interesting observations on the reduction of the pyrexia of acute rheumatism have added much to our precise knowledge of the immediate and subsequent effect of such baths. The methods of the first three observers differ considerably. Brand uses largely, and more especially in severe cases, the general cold bath, cold affusions, and cold wet packings, the water being at a temperature of 50° F., and the affusions being continued for a quarter of an hour or thereabout. Ziemssen's method consists in placing the patient in a bath at 95°, which, in the course of half an hour or so, is gradually cooled down to 60°. He uses the cold wet packing as an adjuvant to the baths.

Riess's method (*Centralbl. für die Med. Wissen.*, July 24, 1880, p. 545) differs from both these in the duration of the bath, and also in the fact that the water is kept at a constant lukewarm temperature. His procedure is as follows: On the day succeeding the admission of a typhoid patient with high temperature, he is placed in a bath at 88° for twenty-four hours. The duration of the bath in the following days depends on the rectal temperature. So soon as the temperature reaches 101.5° the patient is placed in the bath, which is interrupted at 99.5°, until the temperature again rises to 101.5°. Riess claims for this treatment that it not only keeps the temperature in typhoid patients almost normal, but also that, under it, delirious and comatose patients return to full consciousness and gladly remain in the bath.

Notwithstanding the excellent results obtained by Riess, few test trials of this method have been published, and accordingly the detailed observations by AFANASSIEFF (*St. Petersb. Med. Woch.*, 1881, No. 7) of seven cases of enteric fever, treated by prolonged lukewarm baths, are possessed of some interest. In certain respects, Riess's method was not fully carried out. From circumstances of hospital convenience the bath lasted in general only three hours, being repeated twice daily if necessary, that is, if the rectal temperature rose above 101.5°. Sometimes, also, the baths were of a higher temperature than 88°, in one or two cases as high as 95°. As to the general course of the disease in these seven cases, two were specially severe, but in none was the "typhoid" condition developed. Consciousness was clear, headache slight or absent, and sleep good throughout the whole period of the use of the baths. The tongue was seldom coated, mostly clean and moist, and all the patients preserved a good appetite

throughout the disease. Pain in the region of the cæcum and meteorism were generally present, but required no special treatment. Marked diarrhœa was not present in any of the cases, and the bowels were regularly and naturally opened. Two cases had bronchitis, passing over without treatment. The number of baths given was 114, of which 100 lasted three hours; 14 a longer or shorter time. As regards reduction of temperature: on two occasions the reduction was 5.8°; on seven, approximately, 5.5°; on twenty-one, 4.5°; on thirty-four, 3.5°; on twenty-four, 2.5°; on twenty-three, 1.5°; and on three, 1°. The last two classes were mostly those in which the baths lasted for only half an hour or an hour, the rectal temperature being only 101.5°. The temperature was taken in the rectum before and after the bath; and we must here note a practical point of which the observer seems to have been unaware. The temperature immediately after a bath by no means necessarily indicates the reduction of temperature accomplished by it; for Dr. Wilson Fox has shown, from his cases of acute rheumatism, that the temperature may continue to fall six or more degrees, forty or fifty minutes after the termination of the bath.

The conclusions arrived at by the observer are these: 1. The usual reduction is from 3° to 4.5°. 2. In the later stages of enteric fever, the temperature yields more readily than at first. 3. The temperature sinks more readily in the evening than in the morning, the greatest reduction in the evening among his cases being 5.8°, while the greatest in the morning was 4.5°, both these meaning, however, a reduction to almost the normal temperature. The pulse and respirations also sank in number under the use of the bath. The fall in the pulse was in strict relation to the fall of temperature, the diminution being 20, 50, and in some cases even 70 and 90 per cent. The author considers the treatment well suited for hospital cases, and points out that the attitude of the patient in the bath ought to be as comfortable as possible, for which he recommends a waterproof mattress, covered with a sheet, and a movable pillow attached to the frame of the bath.—*London Med. Record*, May 15, 1881.

The Simulation of Typhoid Fever by Acute Tuberculosis.

Dr. SENATOR contributes to the *Berliner Klinische Wochenschrift*, No. 25, an article bearing on this subject, in which he relates a case of acute miliary tuberculosis that during life was supposed to be typhoid fever. The patient was a man aged forty-eight, who, three years before coming under observation, had gone through a severe attack of typhoid. During its third week a very stubborn and intractable hiccough came on, which lasted eight days. There had also been attacks of epistaxis, with hawking up of blood-stained mucus from the posterior nares; but he quite recovered. He subsequently broke his arm, and again recovered without further trouble. His last illness commenced, about five weeks before he came under Dr. Senator's care, with slight shiverings, malaise, depression, and dyspnœa, which obliged him to keep his bed for a few days. When taken into the hospital he was observed to be a fairly well-built man, well nourished, without cachexia, and with a good family history. There were no abnormalities in the circulatory or respiratory apparatus. After some days the spleen was felt to be enlarged, and several roseola spots showed themselves; then epistaxis came on, and some pulmonary catarrh also; and later, hiccough and slight deafness. About three weeks after admission some inflammation and suppuration occurred over and about the left parotid gland, sanious and fetid pus being discharged. The temperature varied from 100° to 104° Fahr. The patient then died. In view of the enlargement of spleen, the fever, and the roseola, a diagnosis of typhoid was made. The man, it is true, had once before passed

through an attack of typhoid, but authentic cases are recorded where an individual may have the disease twice. Moreover, the occurrence of epistaxis and hiccough (which were marked symptoms during the first attack) occurred during his last illness. Finally, the occurrence of a suppurative parotitis seemed to favour the typhoid view. But at the autopsy, not only were there no appearances of typhoid—there were not even any traces of the previous attack. On the other hand, there was a general tuberculosis of both lungs, with enlargement of the bronchial glands. The spleen, the liver, and both kidneys were also tuberculous. —*Med. Times and Gazette*, July 2, 1881.

—

Massive Pneumonia.

GRANCHER was the first to point out the existence of a variety of pneumonia which showed most of the clinical symptoms of pleuritic effusion, and which deserved the special epithet of massive. Recently, two cases of this kind were observed at Professor Lasègue's clinic (*Archives Générales de Méd.*, Feb. 1881). The first was that of a labourer, aged 50, who developed an acute pneumonia. Examination revealed absolute dulness in front and behind on the right side. At the base and in the axillary region, resonance was still found; in the supraspinous and infraclavicular regions, absence of respiratory *bruit;* in the intraspinous region fine moist râles, but neither crepitant nor subcrepitant. Bronchial breathing was very marked at the inferior border of the scapula, extending from the axillary line to the vertebral column. Below this point there was a faint vesicular murmur, distant in sound and largely masked by sonorous *râles*. In front, similar conditions existed, but there was no respiratory murmur. On the left side there were apparently only the signs of bronchitis. There was little cough, and the expectorated matter was not characteristic of any special lesion. The febrile movement was not severe. The patient died soon after admission to the hospital. At the necropsy, the upper lobe of the right lung was found completely hepatized, having assumed a dirty yellowish colour. The other lobes and the left lung were not greatly altered; but the pathological condition which led to the clinical diagnosis of massive pneumonia was found to reside in the bronchial tubes distributed to the upper lobe. They were completely filled to their finest ramifications with a white, elastic, apparently fibrinous substance, which was not found elsewhere. Other cases are cited, and the writers, MM. Beurmann and Brissaud, finally conclude that, although massive pneumonia may at some time during its course closely resemble in its clinical aspects pleurisy with effusion, yet in certain cases bronchial breathing coexists with the dulness on percussion. This respiratory sound will be likely to exist at the beginning of the malady, when the fibrinous exudation has not yet advanced to the root of the lungs. In doubtful cases, an exploratory puncture would appear to be justified.—*London Med. Record*, June 15, 1881.

—

Progressive Painful Inflammation of Arteries.

Mr. J. H. MORGAN, in a paper read before the Clinical Society of London (*British Medical Journal*, April 23), describes the case of a middle-aged man, who during some years suffered at intervals from pain extending gradually from the trunk along the course of some of the main arteries, viz., both brachials, a carotid, a femoral, and extending from it to the arteries of the leg. The retinal vessels were very unusually small, indistinct, and exhibited a double contour. There was at no time any evidence of embolism. He contracted syphilis when eighteen years of age. The symptoms, according to the author, pointed evidently to disease of an artery, probably inflammation of the fibrous coat, since the pain

passed from the centre to the periphery, was in the course of the various arteries, and was made intense by pressing upon the artery affected.—*London Med. Record*, June 5, 1881.

—

Cardiac Lesions in Locomotor Ataxy.

Dr. LETULLE publishes (*Gaz. Méd. de Paris*, 1881) two cases of locomotor ataxy, in which he met with cardiac lesions, already pointed out by M. Grasset of Montpellier. In the first of these cases, the patient, who died suddenly, had atheromatous lesions of the aorta and inefficiency of the aortic valves; in the other, there were also complex lesions of the aortic opening and mitral lesions.—*London Med. Record*, June 15, 1881.

—

Tuberculous Pericarditis.

Tubercular inflammation of the pericardium is a very rare lesion. Laennec only met with two instances of it, and Louis but one. Although cases have been from time to time recorded in medical literature, their total number is not large. Gray granulations in the pericardium have been met with in cases of general tuberculosis in children, unaccompanied by actual inflammation, but the condition of tuberculous pericarditis is most uncommon. An instance of the affection in a girl of nineteen has been lately recorded by Dr. VAILLARD in the *Journal de Médecine de Bordeaux*. The patient died from tubercular meningitis, with extensive enlargement and caseation of the lymphatic glands. The parietal and visceral layers of the pericardium were connected by soft adhesions, and each was covered by false membrane; the visceral layer was studded with granulations and small nodules of caseous tubercle. At a distance from these nodules the microscopical examination showed the proper tissue of the membrane to be somewhat thickened and continuous with a new membrane on the surface, which was almost perfectly organized. Sections through the yellow tubercles showed, even in the thickness of the visceral layer, a small oblong caseous mass, permeated by the remains of tracts of fibrous tissue in process of destruction. No giant-cells were seen in it. Around this caseous centre was a layer of embryonal cells, most marked in the deep layer of the serous membrane. Over the nodule extended the false membrane already described. The subjacent muscular fibres of the heart were fattily degenerated.

From the comparison of a considerable number of cases of tuberculous pericarditis, Vaillard concludes that it is much less common to meet with effusion than with the dry form, the latter having been met with twenty-seven times out of thirty-seven cases; in only ten was there effusion, of a citrine yellow or sanguinolent aspect. In all the cases of dry pericarditis, with one exception, there was complete adhesion of the two layers of the pericardium. Hence it would seem that adhesion is the habitual termination of this variety. The surfaces are covered by false membranes, in which the tubercles are scattered, as well as in the serous membrane proper. Tubercular granulations may, however, develop in the proper connective tissue of the myocardium, and Fauvel has even traced them through the whole thickness of the wall of the heart up to the endocardium. In the less frequent cases in which there is effusion, this is usually abundant, and may vary from 700 to 1600 grammes (Proust), and even 2800 grammes (Richard). This large effusion is so characteristic of the variety that, given a case of chronic pericarditis, the tubercular nature of the inflammation may be suspected from this characteristic. The layers of the pericardium present changes similar to those met with in the dry form, but the false membranes may undergo degeneration and ulceration, so that ulcers form similar in appearance to the specific

ulcers of the intestine. The question has been discussed whether the formation of tubercles is primary and the inflammation secondary, or whether the opposite is the order of events. Cruveilhier, Empis, and Niemeyer have expressed doubts as to the occurrence of tubercles in uninflamed pericardium; and, according to them, the formation only occurs in the depth of the newly-formed false membranes. The facts of the question have often been difficult to ascertain, in consequence of the close adhesion of the false membrane and serous layer, so that it is not always easy to say where one ends and the other begins. But many cases have been observed in which tubercles were seated in the thickness of the serous membrane without any trace of inflammation, as in a case in which, the patient having died from acute tuberculosis, miliary granulations were found on the parietal layer, and three similar nodules on the surface of the visceral layer. This renders it probable that, in some cases at least, the formation of tubercles is primary and the inflammation secondary. But it does not follow that this is the invariable order of events; a simple pericarditis may be the occasion of the growth of tubercles in the inflammatory products.

The dry adhesive form of pericarditis is often overlooked during life. Its course is latent, and pericarditis not being expected in the course of phthisis, it is often discovered only at the autopsy. Any dyspnœa which it causes is obscured in the greater dyspnœa due to the condition of the lungs, and when adhesions form friction disappears. The occurrence of effusion renders the symptoms more obtrusive, so that this form is usually recognized during life. If there are no lung symptoms it may be difficult even to suspect the nature of the pericarditis, but a correct diagnosis is, in these cases, of great importance, since the pericarditis is occasionally the first local manifestation of tuberculosis, as in cases which have been recorded by Virchow, Proust, and Richard.—*Lancet*, May 28, 1881.

The Phenomena of Neuro-muscular Superexcitability during Hypnotism.

MM. CHARCOT and RICHER, in a contribution to the study of Hypnotism in Hysterical Patients (*Le Progrès Médical*, Nos. 15, 16, 1881), draw attention to the phenomenon of exaggerated excitability of the nerves and muscles during certain forms of induced sleep. This phenomenon includes (1) great increase in the tendon-reflexes; percussion on a tendon giving rise to movements not only in the same limb but in the others, to sharper reflex contraction, to prolonged contraction, and to permanent contraction; the contraction may be brought about by kneading, friction, or simple pressure; (2) increased nervous excitability; pressure on nerve-trunks giving rise to spasm of the muscles to which their branches are distributed; (3) increased muscular excitability; pressure on a muscle causing it to contract; (4) a special increased excitability of the muscles of the face, which cannot be thrown into permanent spasm, but may be excited in any of the foregoing ways, and even by simply pressing each one with a small piece of wood, by which means they reproduced most of the experiments of Duchenne of Boulogne, on the partial action of the muscles of the face under the influence of localized faradisation.

The contraction resulting as above described is generally very intense, resisting the most forcible efforts to overcome it, but it may be made to yield, without force, by simply stimulating in the same manner the antagonist group of muscles. When the contraction is not destroyed during the hypnotic sleep, on awakening the patient, the contraction may disappear with the sleep; or it may persist after waking, if we render the patient cataleptic and awaken her during that state; or it may in some cases persist whether the patient be awakened during either the lethargic or the cataleptic state. Such persistent contractions resemble those of

hysteria; and for their reduction it is necessary to hypnotize the patient again, and then to excite the antagonist muscles.

The transference of artificial contraction by means of the magnet is well known, since the experiments at the Salpêtrière in 1878; but it was not known whether such transferred contraction affected exactly the same muscles as were involved in the primary contraction. One of the patients of MM. Charcot and Richer having been hypnotized, and her muscles completely relaxed, the ulnar group were stimulated by touching the right ulnar nerve at the elbow, and a magnet was then applied to the left arm, the muscles of which remained relaxed; at the end of two or three minutes the fingers of the contracted hand began slowly to open, while those of the opposite hand began to assume the position they were quitting, until the contraction was completely transferred. The same result followed when localized contraction was induced by exciting a tendon or the muscle itself.

Anæmia of a limb produced by Esmarch's bandage prevents the manifestation of contraction, so long as the anæmia persists; but as the blood returns to the limb the contraction shows itself. In the former stage, therefore, it may be considered to be latent. This latent contraction may also be transferred by the magnet; so that, while in the bloodless limb no contraction results from exciting the nerve, a magnet applied to the opposite arm develops in it the spasm of the ulnar group of muscles.—*London Med. Record*, June 15, 1881.

—

Glosso-labial Palsy.

Dr. Andrew Clark has recently had under his care a rapidly fatal case of glosso-labial palsy, which is reported in the *Med. Times and Gazette* for July 2, 1881. He says:—

"The chief features of this case are its rapid course (the patient being quite well three months ago), the transient attacks of loss of voice, the progressive emaciation, and the supervention of permanently dangerous and symptomatic phenomena only a fortnight before death—viz., inability to swallow, and loss of voice, and paralysis of the muscles of the pharynx—and the sudden death by syncope. The nerves involved in this disease are generally stated to be the seventh, the ninth, and the eleventh. In this case, the seventh was only very slightly involved, as evidenced by the slight drawing of the right side of the face. The ninth nerve, evidently, was chiefly implicated, as evidenced by paralysis of the azygos uvulæ and the palato-pharyngeus and palato-glossus of the left side, and the paralysis of the posterior portion of the pharynx. Some amount of loss of taste appears to point to impairment of its gustatory fibres also. The vagus had, no doubt, a share in producing the paralysis of the pharynx, and possibly in slowing the circulation by its inhibitory fibres, and causing the final attack of syncope. It is curious to note how partial is the paralysis in this disease very often. I have seen a case which had apparently become quite well under iodide of potassium, and in which the only lesion left was paralysis of the uvula. When we remember, however, how many individual fibres go to make up a nerve—*e. g.*, in the optic nerve probably some 100,000—the selection of these individual muscles becomes more intelligible. Glosso-labial palsy is somewhat rarer as an idiopathic disease than when occurring along with other well-marked nervous diseases. The causation is obscure, and in this case would appear to be from excessive heat and cold. These changes of heat and cold have a remarkable influence in inducing certain diseases of the nervous system—*e. g.*, progressive muscular atrophy, which Charcot has asserted to be very common amongst stokers. No doubt, had a post-mortem been made, a sclerosis in the medulla would have been found,

involving the nerve-roots (or their cells) of the seventh, ninth, tenth, and twelfth. The disease is not always easy to recognize, but in a well-marked case the features are distinctive enough. The above case, however, had been treated for 'liver complaint' before being sent to the hospital."

—

Paralysis from Apoplexy of the Medulla Oblongata.

Herr M. DE BON relates (*Nord. Med. Archiv*, Band xiii.) the case of an unmarried woman, aged 48, who had for two years had a constant dull pain in the neck, which was much increased when she bent the head forwards. In 1878, her sight began to fail. On April 2d, 1879, she had vomiting and giddiness. On May 2d, she had giddiness and nausea when she lay down. Afterwards, she had difficulty in speaking and swallowing; in the afternoon, she lost speech, and respiration became stertorous. The next day, there was complete paralysis of all limbs. The face was immovable; the right eyelid was paretic, and the right pupil dilated; the left eyelid was unaffected; respirations, 60 to 80; pulse, 150; consciousness appeared to be retained. She died on the same day. At the necropsy, the coats of the basilar artery were found to be much thickened, and its lumen reduced. The same condition, but in a less degree, was found in both vertebral arteries, for the space of about one centimetre. There were no dilatations nor depressions on the outer surface of the vessel. The basilar artery was empty; at the part next the vertebral arteries was a thrombus, half a centimetre (0.2 inch) long, which extended a centimetre into the right, and a centimetre and a half into the left vertebral artery. The pons Varolii was pale; the medulla oblongata was very pale and soft; and under the ependyma, corresponding to the eminentia teres, was a small hemorrhagic clot, which, on section, was found to be pale, soft, and homogeneous. Several small clots were found in the cerebellum. The occipital headache, for two years, might have been due to the anæmic condition of the posterior part of the brain and meninges, in consequence of the insufficient flow of blood from the obstructed basilar and vertebral arteries. The symptoms of affection of the medulla oblongata first appeared when thrombosis of the vertebral arteries, and consequent anæmia and softening of the medulla, took place. From this time, the symptoms became distinctly marked: on the second day, all the nervous functions were thrown into a state of inaction; and the patient died, unable to speak, swallow, or move herself, but apparently quite conscious. The thrombosis occurred, possibly, nearly at the same time in both vertebral arteries, since no unilateral paralysis was observed. No microscopic examination of the vessels was made.—*London Med. Record*, June 5, 1881.

—

Temporary Paralysis after Epilepsy.

Dr. HUGHLINGS JACKSON (*Brain*, Jan. 1881), by many and powerful arguments, supports, elaborates, and, we may say, establishes, the theory of Todd and Alexander Robertson, that temporary post-epileptiform paralysis depends on temporary central exhaustion, consequent on the excessive discharge during the paroxysm. Previous observation has shown that local temporary paralyses most usually occur after epileptiform seizures (the spasm commencing in the terminal part of a limb, or in the side of the face), as distinguished from epilepsy proper. Dr. Hughlings Jackson now shows that, in accordance with Todd and Robertson's theory, paralysis also occurs after true epilepsy; it is distributed over all parts of the body, and has hitherto been regarded as weakness, prostration, coma, etc. When the nervous discharge is partial in its distribution; when, for example, one limb only is affected thereby, that particular limb will suffer from the paralysis due to central nervous exhaustion in the paths or centres most intimately con-

nected with it. If the nervous discharge be distributed along various paths to the whole of the body, then the whole body will be affected by the resulting central nervous exhaustion.—*London Med. Record*, June 15, 1881.

—

Softening of the Brain in Puerperal Pyœmia, as the Result of Infection with Micrococci.

In the *Breslauer Aerztl. Zeitschr.*, 1880 (S. 205), two cases are given by LAFFTER with autopsies. In the first, the woman was taken with pains in the abdomen eight days after delivery, these being followed by somnolence, and paralysis of the right side, extremities, and face. Death occurred three weeks after delivery. The following lesions were found at the necropsy: a pyæmic abscess of the lung, enlargement of the spleen, multiple abscesses in the kidneys, recent aortic endocarditis, and softened purulent thrombi in the plexus of veins around the vagina. In the left frontal lobe of the brain was a patch of red softening, almost as large as a hen's egg. On microscopic examination, numerous micrococcus-emboli were discovered in the vessels of the kidneys, and of the brain in the neighbourhood of the softened spot; the latter being in some cases tightly distended with colonies of micrococci, in others containing only scattered chains of micrococci arranged in a serpentine manner. In the second case, the signs of puerperal pyæmia and endocarditis were also found; and, in addition, a patch of red softening, about the size of a hazel-nut, in the right frontal lobe, and in connection with this a purulent meningitis over the convexity of the brain. The histological condition was identical with that of the first case. Clinically, somnolence only, and no local paralysis, was observed.—*London Med. Record*, June 15, 1881.

—

Determination of Albuminoid Degeneration.

Dr. C. ARNSTEIN, of Kasan (*Central. für die Med. Wiss.*, No. 13, 1881) says he has had the opportunity of examining certain growths from the eyelids sent him by Professor Adamuk, to investigate whether they were amyloid or not. He found that some were decidedly amyloid, but others, although the tissue was translucent, gave no amyloid reaction. In some of these latter there was no cell-proliferation; in others, the degenerated parts alternated with patches of cell-proliferation with numerous giant-cells. In one case he recognized the preliminary stage of hyaline degeneration, to which he gave the name of fibrinous degeneration. In the latter, he could distinguish, along the vessels, fibrous finely striated layers, which permeated the adventitia, and gradually became hyaline, in such a manner that the outer layers appeared already grass-like, while the inner were still finely striated. In the next stage, vessels could be seen, the wall of which appeared like thick clear glass rings or hollow tubes; the striation had completely disappeared, and the lumen of the vessel was reduced to a minimum, or quite obliterated. In the tissue itself, he could distinguish with high powers a finely fibrillated granular-looking reticulum, which, at neighbouring spots, was replaced by a bright hyaline stroma. In the narrow meshes of this stroma, nucleated cells and giant-cells were demonstrated by carmine. He has found cochineal-alum a valuable colouring agent for amyloid matter. The amyloid matter is coloured red, while, in the normal tissues, the nuclei are coloured violet, and the protoplasm and ground substance remain colourless.—*Lond. Med. Record*, June 15, 1881.

Formation of Hyaline Tube-Casts.

RIBBERT has already advanced the hypothesis that hyaline tnbe-casts are formed from altered albumen which has transuded into the glomeruli. This coagulation of albumen in the convoluted tubules he believes to be brought about by reason of the acid reaction of the urine. In order to prove this, he makes certain observations, proceeding upon the hypothesis that, if the acid reaction of the contents of the tubules so acted, then the artificial acidulation of the contents of the glomeruli by the injection of acids into the blood would cause a coagulation of the albumen in the Malpighian tufts. In each of two rabbits he clamped one renal artery, and, after an hour and a half, he injected 20 to 30 grains of a 2½ per cent. solution of acetic acid into the jugular vein. In the one animal, the kidney was extirpated thirty minutes after the operation; in the other, one hour. In both cases, hyaline masses of coagulated albumen were found in the glomeruli.—*London Med. Record*, June 15, 1881.

Quantitative Analysis of Chlorides in Urine.

For some time SALKOWSKI has employed Vothard's method for the estimation of chlorides in the urine by means of rhodan ammonium in the urine, which he carries out in the following manner. Ten cubic centimetres of urine are diluted to about 60 cubic centimetres, then acidulated with 2 cubic centimetres of pure nitric acid, and decomposed with 15 cubic centimetres of the silver solution usually employed for the estimation of chlorides (1 cubic centimetre = 0.01 NaCl). The mixture is then vigorously shaken until the fluid has become clear, diluted with distilled water to 100 cubic centimetres, and filtered through a dry filter-paper; 80 cubic centimetres of the filtrate are taken and to this are added 5 cubic centimetres of a cold saturated solution of rock salt; and then the quantity of silver estimated by means of a solution of rhodan ammonium. The latter solution is to be added to the silver until the red colour no longer disappears on shaking. The calculation is very simple.—*London Med. Record*, June 15, 1881.

Estimation of Urea.

In a paper in Pflüger's *Archiv*, Band xxi. p. 248, E. PFLÜGER gives in great detail his reasons for believing that Liebig's method is liable to error to the extent of 14 per cent., and indicates certain rules whereby such error may be corrected. Expressed shortly, the principal error in Liebig's work, according to Pflüger, is, that he assumes that if one have a solution of a substance A, and to it add the solutions of a second substance B, and of a third C, both of which have a chemical action upon A, the result is identically the same, whether B or C be the first to be added, which is not the case. Into the details of Pflüger's method (which he calls the static method) it is not possible here to enter. It depends in great measure upon accuracy of preparation, and upon the care with which the solutions required in the analysis are prepared. Very full directions are given in the original paper.—*London Med. Record*, June 15, 1881.

Surgery.

Arrow Wounds.

Dr. H. S. KILBOURNE, Captain and Assistant Surgeon, U. S. A., recently made some remarks upon arrow wounds before the Buffalo Medical Club, that form an interesting contribution to the literature of the subject.

As arrows were among the first offensive weapons used by man in ancient and barbaric times, so they are still the favourite weapon of many savage tribes. This antique weapon is, however, being rapidly displaced by rifles among those tribes whose enmities with the whites have taught them its superiority. An American Indian of the plains, who has seen a breech-loader and does not possess one, will part with all he has in the world to procure it. The bow and arrow is therefore disappearing, and with them the surgery of arrow wounds will become only a curious history.

The service bow of the Indian is quite a different thing from the dainty affair of the archery clubs. It is short, thick, and strong. It is made among the southwestern tribes of the bois d'arc or Osage range. The string is of raw hide, or buffalo sinew. The arrow is made of pecan or any suitable wood, not too heavy and having a straight, tough fibre. The arrow head, formerly of flint, is now usually made of soft iron, cut by a file into triangular shape. It is let into the split end of the shaft by a short shank and fastened by wrapping with strips of sinew, put on before it is dry.

In hunting and fighting, the warrior is mounted on a swift and active pony, and in using the bow he comes to close quarters. In action he rides at full speed, slipping over to the side of the horse and discharging the arrows from under the neck of the animal. The horse thus acts as a living shield for his body.

The rapidity, force, and precision of the shots are, in some instances, marvellous. As a rule, however, the accuracy is about that of a fair marksman with the pistol, as at a running mark.

There is in the Army Medical Museum, at Washington, a preparation of a portion of the left scapula of a buffalo, with an arrow head impacted in it. The barbed iron head of the arrow has entered the venter and the point protrudes from the dorsum, so that the missile must have passed through the thorax.

The specimen is from a buffalo killed at Fort Sedgwick, in 1860, by a Cheyenne Indian. There are also other specimens of bones, penetrated, perforated, and fissured in various ways, some of them resembling the appearance of glass, through which a pistol ball has been fired a few yards off.[1] The rapidity of the discharge of arrows rivals the fire of the first breech-loader I know of. The precision is sufficient to make it exceedingly uncomfortable for any one in the vicinity.

As the arrow head is secured to the shaft by strips of dried sinew, the wounds inflicted by it have this peculiarity: that in penetrating wounds, the fastening is softened by the fluids of the body, and, when not at once extracted, the head becomes loosened and is detached when extraction is attempted. In such cases it remains as a foreign body in the wound. If bone has been penetrated, the arrow head is impacted in it and held fast by the compact tissue, when extraction may become a difficult and hazardous operation.

The late Gen. Kearing suffered from a penetrating arrow wound of the superior maxillary bone, received in an affray with hostile Indians, about 1855 or 1856, until his death. The arrow head was so pinched and twisted by the hard bone, and attempts at removal were attended by such copious hemorrhage, that the iron was allowed to remain until a secondary operation was practicable. The missile was finally removed in St. Louis, after a severe operation, but the patient never entirely recovered from its effects. At short range, the arrow will perforate a flat bone, as a rib, making a clean cut, or a slight cracking or splitting. There is seldom any comminution or extensive fissuring like that produced by the impact of a conoidal rifle ball with bone.

[1] Dr. Otis, U. S. A., in Report in Surg. Cases in the Army.

In all the specimens showing penetration of the cranium, there is, according to Dr. Otis, little or no fissuring internally or externally. The inner and outer tables are both cleanly divided. This feature distinguishes arrow wounds of the calvaria from all others caused by weapons used in civilized warfare. Indeed, among all weapons I have seen, I know of none capable of making wounds so peculiar.

There are in the army museum specimens illustrating these features and also the impaction of arrow heads.

For the relief of these injuries, it is most natural to seize the arrow and draw it out of the wound. But that will never do. The head will part with the shaft and remain in the bottom of the wound. If not loosened by softening of the sinew, the head, if barbed, will catch in the soft parts and may, in certain regions, work irreparable injury.

Dr. Bill, of the army, has employed a device for these operations which is often of great service. He passes the loop of a wire snare down along the shaft and over the arrow head, and, when in place, secures it by traction on the outer end of the loop. The missile may then be carefully withdrawn entire. When the iron is impacted in the bone, he employs a loop of annealed wire, passed down along the shaft, which serves as a guide. The arrow head is snared by the loop; the ends of the wire are then passed through a long suture-twisters or double canula, which is passed down to the loop; the ends of the wire are then twisted or secured to the handle, and arrow and instrument are withdrawn together. In a case where a Navajo arrow had penetrated the lung to a depth of five inches, Dr. Bill removed it by means of the simple snare first described.

A prominent army officer, now retired from active service, when serving in Texas as a subaltern, was, while in an encounter with hostile Comanches, transfixed by an arrow. The weapon pierced the upper part of the right chest and passed nearly horizontally through the lung, the point protruding at the back, between the scapula and spine, on the same side. He informed me that, at his own request, a silk handkerchief was fastened to the shaft, which was then pushed on through the body, dragging the silk after it through the whole extent of this formidable wound. He recovered from the effects of the wound and from this novel surgical procedure, and served actively for many years after.

In the report of surgical cases in the army since the war, I find the following somewhat similar case, reported by Dr. Goddard, U. S. A. His employé at Fort Rice, D. T., was wounded in February, 1868, by an arrow, which entered his back three inches to the right of the fifth lumbar vertebra and emerged at a point two inches to the right of the ensiform cartilage. During the following evening the patient lost externally about eight ounces of blood, and a small (estimated) quantity internally. He was confined to his bed some two weeks, suffering from irritative fever and circumscribed peritonitis. In four weeks he was walking about, and on July 1st was actively employed. There are no further particulars or comments on this case.

The route of the missile is a mystery. It would seem impossible that it could have been direct between the two wounds, as the intestines, stomach, and liver lie in the way. Both the great cavities would also have been opened. Penetrating arrow wounds of the abdomen are usually mortal.

Of 9 cases reported in detail, 7 were fatal; and of the 2 which recovered, it is doubtful whether the peritoneal sac was penetrated. One of the fatal cases was mine, and, as it may be taken as a type of its class, I will give it here: A cavalry soldier was wounded while approaching an Indian camp at night, near the Canadian River, Texas, by an arrow which entered the abdomen in the left hypochondriac region, making a wound about three-fourths of an inch in length,

through which about eighteen inches of the small intestine protruded. The gut was cut in four places. The wounds in the intestines were closed by sutures and the protruding portion returned through the wound, which was enlarged for the purpose. When found, the man had lain out all night, and was in a state of collapse. He was carried along with the column, in an ambulance, but died on the second day, never having rallied from the shock of the injury.

The great fatality of arrow wounds of the abdomen is so well known to the Indians that in action they usually aim at the umbilicus.[1]

Another case, which I personally observed, is so unique that I will briefly give its outlines. It is an example of a penetrating arrow wound of the lower part of the trunk. The operation for its relief was done at Fort Sill, I. T., by Dr. Forwood, of the army, who reports the case. I assisted him and saw the patient up to the date of his removal.

"Latimore, a chief of the Kiowas, aged 42 years, applied at Fort Sill for treatment, with symptoms of stone in the bladder. In 1862 he had led a band of his tribe against the Pawnees, and was wounded in a fight. Being mounted, and leaning over his horse, a Pawnee, on foot and within a few paces, drove an arrow deep into his right buttock. The shaft was withdrawn by his companions, but the point remained in his body. He passed bloody urine soon after the injury, but the wound soon healed, and in a few weeks he was able to ride without inconvenience. For more than six years he continued at the head of his band and travelled on horseback many hundreds of miles every summer. A long time after the injury he began to feel pain in urination, which increased, until he was forced to reveal the sacred secret, as it is regarded by the Indians, and to seek medical aid. The urine was loaded with blood, mucus, and pus; the introduction of a sound indicated a large, hard calculus in the bladder. Judging from the cicatrix and all the circumstances, it was apparent that the arrow had passed through the glutic muscles and the obturative (sciatic?) foramen into the bladder. On Aug. 23d I removed the stone by the lateral operation. The calculus was phosphatic, and weighed eight hundred and fifteen grains. On section of the stone, the arrow point was found imbedded near its centre. It was of iron, and had originally been about two and one-half inches long, by seven-eighths of an inch broad in its widest part. The urine began to pass by the natural channel on the third day, and on the seventh day it had nearly ceased to flow from the wound. But the restless spirit of the patient's band could no longer be restrained; open hostilities with the whites were expected to begin every moment, and they insisted on his removal. He needed purgatives on the eighth day, which they refused to allow him to take; on the following day they started with him to their camp, sixty miles away. Fourteen days after he is reported to have died. But his relatives have since assured me that the wound had healed, and that no trouble arose from it."

Notwithstanding a narrow pelvic outlet and the large size of the stone, there was every reason to expect a favourable result in this interesting case. These Indians possess remarkable powers of endurance and recuperation from wounds, due, doubtless, to their active life in the open air of the Western plains. But it is possible that the case may have been complicated by an induced disease of the kidneys.—*Buffalo Med. and Surg. Journal*, July, 1881.

—

Ununited Fracture of the Olecranon treated by Suture of the Bones.

At a late meeting of the Clinical Society of London (*Lancet*, June 4, 1881), Mr. MacCormac read notes of a case of Ununited Fracture of the Olecranon

[1] Dr. Bill, U. S. A.

Process, in which Bony Union was obtained by Sutures of the Bones. The patient (who was exhibited) was a piano-tuner, twenty-six years of age, who four months before coming to St. Thomas's Hospital had fallen upon the right elbow, and sustained a fracture of the olecranon. When admitted the limb was wasted, especially the triceps; there was no power of active extension; the line of fracture ran across the base of the olecranon, the detached portion being separated by two inches, and fixed to the back of the humerus, the condyles of which could be felt in the gap, no uniting medium being perceptible. On Jan. 6th Mr. MacCormac made a vertical incision three inches long, exposing the fractured bone and the articulation. There was no trace of uniting material, the fractured surfaces were covered with smooth fibrous tissue, and adhesions existed between the detached process and the condyles, and also between the end of the humerus and ulna. These adhesions were dissected out, and the periosteum being reflected, a thin layer of bone was cut off with a chisel, and by means of two wire sutures through holes drilled in the bone the surfaces were brought into close apposition. The wires were twisted and cut off so as to project at the centre of the wound, which was afterwards closed with catgut sutures. The operation was performed antiseptically, the joint being washed out with carbolic solution (1 in 30) before closing the wound. The first dressing was made on the fifth day, when the wound was found to be united, except where the bone-sutures emerged, and these were removed in twenty-one days. In forty days the patient left the hospital with very good active movement at the elbow-joint, and apparently firm bony union at the seat of fracture. From first to last he had no pain or inconvenience. The wound healed without a drop of pus; the temperature occasionally rose to 99°.8; it was otherwise normal throughout. He has now perfect power of active extension. The arm cannot be made absolutely straight, but he is able to follow his trade as well as before.

Mr. LISTER believed he was the first to perform an operation of a similar nature many years ago in Edinburgh. The patient was an engineer in the prime of life, who had sustained a fracture of the olecranon. Mr. Lister exposed the ends of the fragments by a longitudinal incision; and after paring away the surfaces, drilled the fragments and tied them together by strong silver wire, using a single suture, which was more convenient than a double suture, for it remained in the line of incision. The result was, as in Mr. MacCormac's case, there was no inflammatory or constitutional disturbance. The man left with bony union and resumed his occupation. Since then, at King's College Hospital, he had similarly treated another case with like result. In neither was the upper fragment fixed to the humerus, as in Mr. MacCormac's case; nor was the separation between the fragments so wide. It was refreshing to hear antiseptic dressings spoken of as a matter of course; but he supposed few members of the Society would perform such an operation as the free opening of a joint without such antiseptic precautions as we possess, which afforded such security against complications.

—

Antiseptic Osteotomy of the Tibia; Rapidly fatal Carbolic Intoxication.

Mr. PEARCE GOULD at a recent meeting of the Clinical Society of London (*Lancet*, May 21, 1881) read a paper on a Case of Antiseptic Osteotomy of the Tibia, in which rapidly fatal carbolic intoxication occurred. A lad, eight years of age, of robust appearance, was admitted, under his care, into Westminster Hospital in Oct. 1880, with rickety deformity of the legs, especially of the left tibia. Other treatment had been perseveringly tried at the National Orthopædic Hospital for some time without avail, and he was sent in for the purpose of having osteotomy performed. His general health was very good. On Oct.

30th chloroform was administered, and the left tibia divided with McEwen's chisel, with a careful observance of the details of Listerism. He quickly recovered from the effects of the chloroform, and slept well through the night; next morning (Oct. 31st) he took his breakfast and appeared quite well; temperature 98.4°. At 11 A. M. (twenty-one hours after the operation) he vomited; and vomited a watery fluid repeatedly up till 9.30 P. M. He also passed two orange-coloured loose stools. At 7 P. M. he was rigid, and at 8 P. M. very restless; at 9 P. M. he was almost unconscious, he was breathing hurriedly, pulse almost imperceptible at the wrist. At 10 P. M. Mr. Gould saw him; he was then conscious; lying quiet and quite flat, respiration 44 per minute, air entered lungs freely, pulse very small and rapid, pupils small. He died, asphyxiated, at 2.30 A. M., Nov. 1st, thirty-six hours and three-quarters after the operation. There was complete suppression of urine after 11 A. M. Temperature rose to 100.2°, and fell to 99.6° at 2 A. M. on Nov. 1st. The treatment consisted in the application of warmth and stimulants to the surface, and brandy internally. At the autopsy all the viscera were apparently healthy, with the exception of congestion of the tracheal and bronchial mucous membrane, and excess of mucus in these tubes, and slight congestion of the lungs. The left side of the heart was empty, the right side contained partly-clotted blood; blood in smaller veins all fluid, in the larger partly in soft clots, all of it black. No petechiæ; no staining of endocardium or intima; no sign of fat embolism. Bladder empty. A small blood-clot in the wound; no crushing of the medulla; no thrombosis of tibial vessels. Microscopic preparations of the organs were made for Mr. Gould by Dr. Heneage Gibbes, some of which were shown at the meeting. From these it was seen that there was thrombosis of the capillaries and smaller vessels of the lungs with minute spots of round-cell inflammatory exudation. Similar minute inflammatory foci were also found in the kidneys, while sections of the stomach showed intense inflammation of its mucous surface, only traces of its glands being visible, and at places the process was evidently advancing to suppuration. No sign of fat embolism.

In discussing the cause of death Mr. Gould pointed out that shock, chloroform, the acute specifics, erysipelas, septicæmia, pyæmia, and fat embolism might be excluded, as was also the ingestion of any irritant matter, but yet both the symptoms and pathological changes showed evidence of the circulation of some irritant in the blood. The symptoms were individually considered, and it was shown that the vomiting, diarrhœa with orange stools, collapse, rigidity, restlessness, loss of consciousness, very hurried respiration, slight rise of temperature, and death from asphyxia, were the symptoms observed in cases of undoubted carbolic intoxication. The urine passed before the onset of vomiting appeared to be normal, and was not preserved; the suppression of urine later on was a new fact in such cases. The softly coagulated and black blood had been noted before, but there was no record of any microscopical examination of the apparently healthy organs usually found. The quantity of acid absorbed was no doubt small, and the great susceptibility of the patient to its toxic effect must at present be spoken of as an idiosyncrasy; but from the absence of other cause, and of any facts to negative the supposition, as well as the agreement of the symptoms and post-mortem pathological changes in the main with those observed in cases of carbolic intoxication, he was forced to the conclusion that such poisoning was the cause of death.

Professor LISTER remarked upon the interest attaching to the suppression of urine, which he had not met with before. He had no doubt that Mr. Gould's view must be accepted, that this patient was one of those who had an unfortunate susceptibility to the toxic effects of carbolic acid. He had met with cases of such susceptibility, and one he called to mind was a lady whose breast he removed and

dressed in his usual manner; intense symptoms of carbolic poisoning came on, and boracic lint was substituted for the gauze dressing, but the spray was used when the lint was changed, and this was sufficient to keep up the symptoms, which only abated when its use was discontinued. As an instance of the special local susceptibility of some patients, he mentioned a case of chronic synovitis of the knee-joint, which he opened and dressed antiseptically, and next day he found all the skin under the gauze intensely red and irritated. It had been stated that there was no antiseptic that could with safety replace carbolic acid, though several had been tried; but he was in a position to say that the oil of Eucalyptus globulus, if used properly, is a powerful and perfectly reliable antiseptic, and is also quite unirritating and without toxic effects. If the oil be made into an emulsion with spirit and water, and then used, it very quickly evaporates; but he had found that gum damar holds it exceedingly well, and the mixture remains soft and strongly odorous of the oil even at the end of several weeks. He had used a gauze prepared with a mixture of one part of the oil, three of damar, and three of paraffine, and he was able to assert that it might be thoroughly trusted as an antiseptic where carbolic acid was unadvisable.

—

Trepanation of the Ilium in a Case of Pelvic Abscess.

The patient, a tailor, aged 24, had disease of the lumbar vertebræ, a cold abscess starting from which had burrowed into the left hip-joint, and invaded the whole pelvis (*Deutsch. Zeitschr. für Chir.*, Band xii.). An opening above Poupart's ligament not affording sufficient drainage, Dr. G. FISCHER trephined the ilium at its upper and posterior part, and afterwards established a transverse drain across the pelvis. The patient died twenty-five days later from exhaustion, due to prolonged suppuration and progressive pulmonary tuberculosis. The necropsy showed that stagnation of pus had not taken place in any part of the pelvis; and hence Fisher considers that he has established the justifiability of trephining the ilium to obtain a counter-opening in cases of pelvic abscess.—*British Med. Journal*, May 7, 1881.

—

Resection of Large Trunk-Veins.

PILZER opposes strongly (*Deutsch. Zeitschr. für Chir.*, Band xiv. Heft 21) the prejudice against ligature of large veins, citing recently recorded cases to prove that the fear of pyæmia is groundless. He gives in detail six cases from the Heidelberg surgical clinic. In all six, malignant disease was present; and the internal jugular vein was resected in four cases, both internal jugulars in another, and the femoral vein in the sixth. All the cases recovered. Resection of the vein is much to be preferred to the dissection of it out of the tumour, with the great risk of recurrence of the tumour from fragments left on the vein.—*British Med. Journal*, May 7, 1881.

—

Treatment of Vascular Tumours by Electrolysis.

Dr. NIEDER, in the *Archives of Ophthalmology*, March, 1881, quotes some illustrative cases. In two of them, a tumour consisting of large veins exerted such a pressure on the upper eyelid that the eye could not be opened. In all instances, a complete cure was effected without any untoward symptoms. He employed from four to six cells (model of Spamer), with a key to connect or interrupt immediately. The needles may be of steel, although a platinum needle is preferable for the positive electrode, to prevent oxidation and permanent staining of the punctured spot. Both needles are introduced into the tumour, and left in place for the space of one to three minutes, whereupon the site of the

negative pole is charged according to the size of the growth. The bubbles of hydrogen arising at the negative needle may disturb the tissues, but are harmless; moreover, they are readily dispelled by pressure. At each sitting a few punctures, not over five or six, are made, while the number of sittings varies according to the size and the location of the angioma. The immediate effect is hardening and shrinkage from coagulation of the blood. Some suppuration occurred in all instances but one, which resulted in loss of substance or formation of unexpected cicatrization. Antiseptic after-treatment was maintained.—*London Med. Record*, June 15, 1881.

—

Neuritis in Stumps.

In an original contribution to the first number of the *Revue de Chirurgie*, Dr. G. Nepveu, of Paris, after a short review of previously recorded cases of neuritis in stumps, relates a case, observed by himself, of ascending neuritis in the leg after amputation of the foot for gangrene from endarteritis. About four months and a half after the operation, the extremity of the stump ulcerated, and the patient, a man aged 44, suffered from severe shooting pains, which reached to the middle of the thigh, from painful contractions of the flexor muscles of the stump, and also from pain and convulsive movements of a similar character in the sound leg. Removal of the painful stump by amputation just below the seat of election was ultimately followed by complete relief, although the stump left at this second operation ulcerated and was very tender for about four months. On examination of the amputated stump, the posterior tibial nerve was found to be thickened and adherent at its lower extremity to the cicatrix; and the lower portions of the anterior tibial and internal saphenous nerves resembled fibrous cords. The microscopic appearances of these nerves even at their proximal extremities indicated a chronic interstitial and parenchymatous neuritis, that is to say, an inflammation affecting both the connective tissue and the nerve elements. This condition, M. Nepveu states, accounts for the convulsive movement of the stump, its ulceration, and the severe pain felt by the patient. Moreover, it enables us to understand why the sound limb had also been involved in the spasm, and why, after the second amputation, relief of the pain resulted very slowly and not immediately. Ascending neuritis in a stump affects, it is stated, two very different forms—the simple form and the complicated. Simple ascending neuritis may be accompanied by persistent neuralgia, or by trophic disturbances in the stump. The complicated ascending neuritis presents itself in one or other of two different aspects. Sometimes it attacks the other and sound limb on the side of the stump—ascending neuritis and unilateral myelitis. At other times the myelitis is called transverse, and then the surgeon has to deal with paralysis of the bladder, and paralysis, neuralgia, or contracture of the corresponding limb on the opposite side. The myelitis may be followed by rapid death. M. Nepveu regards his case as one of recovery. Attention is directed to M. Verneuil's practice of resecting nerve-trunks in the flaps during amputation. This resection, it is thought, would probably result in diminishing among those who have submitted to amputation the number of instances of neuritis, whether ascending or localized. In confirmed cases of neuritis of stumps, surgical intervention (reamputation, neurectomy) has been attended with varying success.—*London Med. Record*, May 15, 1881.

—

The Treatment of Neuromata by Enucleation.

Mr. E. Downes, in the *Lancet*, April, 1881, suggests that, in many cases of nerve-tumour, the morbid mass may be shelled out by a longitudinal incision,

instead of excising the growth with a portion of the nerve itself, or amputating the limb, as in some cases has been done. Three cases are related in which this mode of treatment was successful, the nerve-fibres completely surrounding the tumours, which lay in the centre almost entirely unconnected with the nerve itself. In one case, in which a neuroma of the median nerve was treated by excising the mass with the included portion of the nerve, a large number of smaller neuromata spontaneously disappeared after the larger one was thus removed. [Prof. Kosinski narrated a somewhat similar case (*Medical Times and Gazette*, November, 1874, p. 558); here, after a neuroma of the small sciatic had been excised, a large number of similar tumours spontaneously disappeared.] —*London Med. Record*, June 15, 1881.

—

Removal of the Kidney for Nephrolithiasis.

At the Charing-Cross Hospital is a lad aged fifteen, from whom Mr. BARWELL removed a kidney on May 5th, and who is now convalescent. The boy had been under observation for about a year with pyelitis and retro-peritoneal abscess. An incision was made about ten months ago, with the effect of mitigating the symptoms. The wound had healed, leaving only a sinus. In April, by sounding through this passage, Mr. Barwell detected a stone. Yet although the lad was becoming very anæmic, with irregular hectic temperature, no consent for operation could be obtained until the above date, when lumbar nephrectomy was performed. Two peculiarities rendered the removal unusually difficult—viz., the dense thick cicatricial tissue and the proximity of the rib to the ileum. Mr. Barwell cut through the tissues, and came upon the kidney with the stone impacted. An endeavour to extract this latter caused copious bleeding, hence the operator rapidly enucleated the gland, and passed a ligature round the pedicle *en masse*. Since want of room forbade removing the kidney entire, it was divided and extracted in two parts. The operation was thus completed very quickly, and with scarcely any loss of blood. Since then the boy has been going on uninterruptedly well, his temperature becoming normal and regular, the wound being now nearly healed. This is, we believe, the second successful case of removal of the kidney for stone.—*Lancet*, June 4, 1881.

Rhinitis and Plugging of the Nose.

GOTTSTEIN, in the *Berl. Klin. Woch.* 1881, No. 4, defends his treatment of ozæna by means of a cotton-wool plug against the adverse criticisms of different writers. He holds to the following opinions: 1. Plugging is the best known means of preventing the formation of crusts in rhinitis having a tendency thereto. 2. Fetor arising from the so-called atrophic rhinitis is immediately removed by plugging, not so that arising from necrosis. 3. Plugging is effectual in atrophic rhinitis, only when the plug or tampon is in actual contact with the diseased mucous membrane. The tampon ought to be 1½ to 2 inches long, and at the utmost a fifth of an inch thick, so that it may reach almost to the posterior nares. Both nasal cavities should never be plugged at the same time. The plug should remain, as a rule, two to three hours *in situ;* but sometimes it may remain as much as twelve hours, and some patients wear it during the night. Medical treatment is, he says, useless, but a vigorous nasal douche in the intervals is beneficial. In the hypertrophic form, the plug readily causes bleeding and pain. In defect of the septum with formation of crusts, plugging gives most excellent results.—*London Med. Record*, June 15, 1881.

Discovery of the Micrococcus of Syphilis.

Dr. AUFRECHT of Magdeburg (*Central für die Med. Wiss.*, No. 13, 1881) nnounces that he has discovered in syphilitic condylomota a micrococcus, which ıay be recognized by the following characters. The single cocci are of rather oarse grain; they are generally of the form of diplococci, or two joined together, nd the number of these is greater than of the single cocci. They are very seldom threes. They are stained deeply by fuchsin. He has found them in six cases; ut in one, where the condyloma was ulcerated, and, in another, where it had een painted with corrosive sublimate, they were very scarce. He, therefore, xcludes ulcerated condylomata, or those which have been treated specifically. o obtain the micrococci, the condyloma should be incised with a lancet, and the ood sponged away; then a drop of the serous fluid that follows should be col-ected on a cover-glass, which is put under a bell-jar for twenty-four hours to ry. At the end of that time, a drop of a half per mille solution of fuchsin is aced on an object-glass, and the cover-glass is laid on it. The excess of fuchsin wiped away after two or three minutes, and the object examined with Hart-ick's 9A immersion-lens. To preserve the object, he puts a little dammar var-sh around the edge of the cover-glass.—*London Med. Record*, June 15, 1881.

—

Effects of Excision of the Syphilitic Chancre.

M. MAURIAC reports (*Gazette des Hôpitaux*, 1881, Nos. 7, 10, 14) seven care-lly recorded cases in which he excised the initial lesion of syphilis. In six, cision was performed at periods varying from four to sixteen or eighteen days ter the appearance of the sore. In the seventh case, the initial lesion was ex-ed about fifty hours after it had been first noticed, and before there was the ast trace of glandular enlargement; but in this, as well as in all the others, the eration was unsuccessful in preventing further development of the disease.—ondon *Med. Record*, June 15, 1881.

Pathological Anatomy and Pathogeny of Gonorrhœal and Urethral Epididymitis.

In a paper lately read before the Société de Chirurgie (*Bull. et Mém. de la c. de Chir.*, 1881, No. 2, pp. 119, 155), M. TERRILLON details his views on is subject, derived from a study of cases observed by himself and others, and experiments made by himself on dogs, by injecting irrigating fluids into the s deferens. 1. *Pathological Anatomy.*—There are four different degrees of flammation of the vas deferens. (*a*) In the first, the mucous membrane is one attacked, and presents all the characters of catarrhal inflammation. The ithelium loses its cilia, and the submucous tissue becomes swelled and infiltrated th lymph-corpuscles. The vas deferens is not altered perceptibly when ex-ined externally, and, therefore, this degree of inflammation cannot be recog-zed clinically. (*b*) Much more frequently the inflammation extends to the ro-muscular walls of the vas deferens, which becomes swollen to two or three nes its normal size. The bloodvessels and lymphatics are also much dilated.) The inflammation may spread to the cellular tissue of the spermatic cord, nen the whole becomes welded into a mass, of which the various constituents nnot be recognized. (*d*) The inflammatory process may reach the connective sue and scrotum. During the course of the inflammation, the vas deferens ntains a yellow fluid, with a large number of pus corpuscles, and a smaller num-r of large granular cells. Spermatozoa are at first present, but disappear if e inflammation be prolonged. The tail of the epididymis is the part chiefly

attacked. On section, the colour is grayish-green; the tubes are mostly dilated, and little foci resembling abscesses are seen. The intertubular connective tissue is increased, hardened, and infiltrated with lymphatic cells and pigment-granules. In the body of the epididymis the changes are less marked, and still less so in the globus major. No appreciable alteration, except congestion, takes place in the testis proper. The tunica vaginalis is always affected in acute epididymitis, by the formation of false membranes and the effusion of serum. 2. *Results and Termination.*—The phenomena disappear in the inverse order of their appearance. In about a month, the globus minor and vas deferens only remain affected. The latter remains thickened for several months. The author does not agree with Gosselin, who is of opinion that the excretory duct becomes blocked. Terrillon thinks that obliteration is not necessary to explain the absence of spermatozoa; but that their absence is due in many cases to a modification of secretion—in short, to a persistent catarrh of the mucous membrane of the vas deferens and globus minor. In his experiments on dogs, the author found the spermatozoa absent, or nearly absent, from an early stage of the inflammation, and before obliteration had had time to take place. 3. *Development of Epididymitis.*—The sole theory which is admissible, and proved by pathological anatomy and experiment, is the propagation of the inflammation along the ejaculatory ducts and vas deferens. All clinical facts accord with this, viz., first, the appearance of epididymitis at the time when the inflammation has reached the prostatic region; second, the occurrence, in most cases, of swelling and pain in the course of the vas deferens before the epididymitis itself becomes affected. The theory of metastasis is untenable.—*London Med. Record*, June 15, 1881.

—

Colour-Blindness.

It has long been felt desirable that legislative measures should be taken to protect the public from the dangers to which they are exposed by the employment of the colour-blind in positions in which safety is dependent on colour-perception. Statistics have been industriously collected by our Continental and Transatlantic *confrères* as to the prevalence of colour-blindness, but it is obviously necessary that our legislative bodies should be supplied by trustworthy, accurate data as to the frequency of colour-blindness amongst our own population before they can be urged to frame laws for the public safety. The Ophthalmological Society has, therefore, done good service in instituting an inquiry into the prevalence of colour-blindness in the United Kingdom. The Report of the Committee appointed to inquire into defects of sight in relation to the public safety was read at a meeting of the Society held on the 7th inst. by Dr. BRAILEY, from whose lucid and able statement we gather the following particulars:—

The inquiry extended over five months, and the examinations were conducted by gentlemen of experience. The material was collected from various sources, consisting of public institutions, schools (public and private), the Metropolitan Police, and the Coldstream Guards. The number examined (18,088) was sufficiently large to justify deductions from the observations. The examinations were made by the matching of coloured wools, following, in the main, the method of Holmgren. Certain cases were also tested by coloured lights, as exhibited in the instrument of Donders, and also by means of a lamp designed by Mr. Nettleship, in which is employed the actual coloured glass used in railway signals.

Colour-blindness was taken as an inability to distinguish from each other two or more colours; but persons who had simply confused blue with violet, or green with blue, had not been ranked with the colour-blind. It was clearly distinguishable from a defective knowledge of the names of colours, and from defects of

vision in other respects. Those were recorded as *slightly colour-blind* who had ailed to distinguish from each other the pale shades only of different colours—istaking, for example, gray or buff for green, and even mauve, yellow, or pink. Those who, besides failing as above, could not recognize the difference between ed and green, matching either scarlet with green, or rose colour with green, gray, r violet, were considered *pronounced colour-blind*. Three cases only were dis-overed where there was a total failure of the recognition of *all* colours, these eing only distinguished as shades. In the vast majority deficient recognition of wo colours only was conspicuous. These associated colours were either red and reen, or blue and yellow. Failure to recognize blue and yellow was rare, and om its little practical importance these cases were included as *slight* cases of olour-blindness. In every one of the *pronounced* cases of colour-blindness (617 n number) there was blindness to red and green.

All persons with pronounced blindness to red and green were found utterly apable of naming with certainty a red or green light when exhibited singly. ll failed, also, when the distance and intensity of illumination of the coloured ght were unknown. The pronounced colour-blind were divided, as far as prac-cable, into two groups, in accordance with the definitions of Continental authori-es. Those matching rose-coloured wools with dark-blues or violets, and scarlet ith dark-greens or browns, were called *red-blind;* while those matching the se with grays or greens, and scarlet with light-browns or greens, were called *reen-blind*. Notwithstanding that many colour-blind stood, as regards the ools, in a position intermediate between the two groups, this division still ap-eared to the examiners to have a practical value, as the red-blind failed to ppreciate at all, even as a light, except at a much shorter distance than normal, light viewed through glass of the purest red obtainable; whereas the green-ind appreciate it at the full, or nearly the full, normal distance. Red-blindness ppeared to be, in the United Kingdom, a little more common than green-blind-ess.

Coming now to the numerical results, we find that of the 18,088 persons ex-mined, 16,431 were males and 1657 were females. Deducting from the males rtain groups of cases specially selected in the expectation of finding peculiari-es, there remained 14,846 with an average of colour-defects of 4.76; whilst mong females, making similar deductions, there remained 489, with a percent-e of only .4. Moreover, in addition to the striking difference in the prevalence colour-defects in the two sexes, it should be mentioned that the forms encoun-red in females were nearly always slight.

In certain classes of persons exceptional prevalence of colour-blindness was und. Thus, among male Jews it was 4.9 per cent.; among male Friends, 9 per cent.; among the male deaf and dumb it reached the extraordinarily gh rate of 13.7. Among females of each of these groups the percentage was ss high. It appeared also, that the prevalence of colour-defects was lower mong the more educated and socially higher classes. For example, at Eton the rcentage was 2.46; among medical students and sons of medical men it was 5; in middle-class schools it was 3.5; and among the police, and schools of out the same class, 3.7. On the other hand, those with colour-defects were t intellectually inferior to those of the same class without these defects. Luna-s do not present the peculiarity more frequently than the sane. The preva-nce was found to be about the same in adults and children, and in urban and ral districts. There appeared to be a higher percentage of colour-blindness in eland than in England, but this might be accounted for by the differences in the cial classes examined.

With regard to the causation of colour-blindness, Dr. Brailey is inclined to

regard it as due in most cases to a congenital physical defect, either in the eye or brain, occurring in the first instance as an accidental variation, and, when once existing, liable to be transmitted by descent. It was to the frequency of intermarriage that the high percentage among the Jews and Friends was to be ascribed. The heredity of the defect was strikingly illustrated by some cases alluded to by Messrs. Frost and McHardy. The former referred to a colour-blind who had seven sons, six of whom were know to be colour-blind. None of the daughters had the defect, but one had a colour-blind son. Dr. Brailey is also of opinion that colour-blindness, especially the slighter forms, may arise from defective colour education in infancy, and hence it is that females, from the greater attraction colours have for them at an early age, and the greater attention paid as a sex to colour-distinctions, are less frequently the subjects of the defect.—*Med. Times and Gaz.*, April 30, 1881.

Midwifery and Gynæcology.

The Earliest Recorded Case of Abdominal Section for Extra-Uterine Gestation.

At the March meeting of the Obstetrical Society of Edinburgh Dr. C. E. UNDERHILL, in presenting a historical note of a remarkable case of abdominal section in the sixteenth century, said that "the triumphs achieved by abdominal surgery of late years lend a special interest to cases in which operations involving the opening of the abdomen were performed by the older surgeons. The case I am going to relate appears to be one of the first in which a surgeon ventured to make an incision into the abdomen for the purpose of removing the remains of an extra-uterine gestation; and it is the more striking as the operation was performed during the existence of a second and natural pregnancy, and the patient recovered without any interruption of the pregnancy, which terminated naturally in due course. I came across it in the voluminous collection of curious cases collected by John Schenck of Grafenberg, which was published in Latin in Frankfort in 1609, under the title, *Observationum Medicarum, Rararum, Novarum, Admirabilium, et Montrosarum Volumen.* The work is divided into seven books, and contains upwards of a thousand folio pages. The cases are collected from the writings of a large number of authors, of whose works a long list is given at the beginning of the volume. The case in question is quoted from the history of remarkable cases of Marcellus Donatus, and is to be found in Book IV. page 660, of Schenck's work. It was as follows: In the month of March of the year 1540, at Castrum Pomponii, commonly called Pomponischi, in the province of the Lords of Gonzaga, not far from the river Po, there lived a woman whose name was Lodovica; but, in consequence of her great size, she was commonly called La Cavalla. Now this woman had at one time been pregnant; the fœtus had died in utero, and the soft parts had become putrid and been discharged through the vulva, while the bony parts had been retained within her. When she had recovered her health, she again became pregnant. Her health soon became seriously impaired, and she passed into a condition of the greatest danger. At this time there chanced to come to these parts a certain surgeon, whose name was Christopher Bain, one of those who journey about, passing from town to town. As soon as he heard of this woman's condition, which was fully explained to him by some of the neighbours, he offered to try and restore her to health, on condition that they should put her unreservedly into his hands, including her body if she died (*ac mortuam*), and should agree to pay him ten golden pieces if she recovered. Her relatives, who were poor persons, accepted his offer, some

f the wealthier people in the neighbourhood helping them and promising to pay
ie money. The man, who was ignorant of letters, but a bold fellow, had the
oman tied up, and set about the operation. Having slowly dissected through
ie longitudinal muscles of the abdomen and the peritoneum, he at last opened
ie uterus itself, and extracted the skeleton of a male child. He washed out the
erus with warm wine mixed with certain aromatics, and united the lips of the
ound by a suture, having burned with the actual cautery the part that was sewn
(*candentique ferro partem inconsutam inurit*). Wonderful to relate, the
oman recovered, and in due time bore the other child, not only alive, but abso-
tely uninjured in any way. She subsequently conceived, not only once, but
ur times, carried her children to the full time, and was safely delivered. The
se I have given is a remarkable one, but I am able to bring witnesses to its
ality, namely, Dominus John Baptist Zorzonus, and Alexander Begher, Domi-
is Frederick de Felini, and Dominus Leonellus Zorzonus, and Antonius Mai-
hus or Mazzuchinus, and several others, who were present at the whole opera-
on.—*Marcell. Donat. Hist. Med. Mirab.*, lib. 4, c. 22," from *Edin. Med.*
urnal, July, 1881.

—

Another Successful Case of the Müller-Porro Operation.

Dr. A. Breisky, of Prague, reports in the *Centralblatt f. Gynäk.* (p. 238) a
ccessful case of Porro's operation. The operation was performed on a 28-year
l woman, who had been in labour over two days. The pelvis was "asy-
etrical, generally contracted, flat, and rachitic," of the third degree of defor-
ty, and with the conjugata vera measuring 2.7–2.9 inches. The child pre-
nted by the vertex in the first position. The patient was in good condition,
d had no tenderness over the hypogastrium. Operation under thymol spray.
cision from a hand's breadth above the umbilicus. The unopened uterus was
lled forward through the wound, and two strong wire ligatures passed round
e supra-vaginal portion. These could not be ligatured at first on account of
e head bulging into the cervix. The uterus was opened, and the child with
ne difficulty removed. It was asphyxiated, but was soon brought round. The
atures were, immediately on the birth of the child, drawn tight by means of a
ntrab's apparatus, and the uterus, with the placenta *in situ*, and ovaries cut
. No sponging of the peritoneum was necessary, as nothing had escaped into
The stump was fixed by a long needle to the lower angle of the wound.
ie wound was closed with deep silver and superficial silk sutures. No drainage-
be was used. On the thirteenth day the needle was removed, on the fifteenth
d sixteenth the ligatures, and on the twentieth the sloughing portion of the
mp separated. The stump wound healed without leaving a fistula by the
th week. The author states that the procedure he followed—Müller's modi-
ation of Porro's operation—is easily carried out, and is safer than any of the
ier methods, and that the intra-peritoneal method, by whichever way the
mp is treated, is so unsafe as to be inadmissible.—*Edin. Med. Journal*,
ly, 1881.

—

Enucleation of Subperitoneal Fibromata through the Vagina.

Czerny relates (*Wiener Med. Woch.*, April 30, 1881) two cases: the first
ne by Sutton, in which the vaginal roof was incised, and the tumour drawn
t of the peritoneum through the vaginal incision. The tumour was attached by
oroad pedicle to the posterior wall of the uterus. The pedicle was cut through,
d the tumour delivered by an ordinary midwifery forceps. Some small intestine
otruded, which was replaced with great difficulty. Death occurred after four

days. Necropsy revealed perforation of the small intestine by the manipulations employed during the operation. The second case, by Derweer, was one of large retro-uterine fibroma, pressing on the ureters, and causing retention of urine. After incision of the posterior vaginal wall, the tumour was drawn outside the vulva by a small forceps, together with the uterus, and the left ligament and ovary. The capsule of the tumour was opened, and the tumour enucleated, without cutting into the peritoneum. Silk sutures were inserted into the wound. Recovery took place at the end of six weeks. The tumour weighed 324 grammes. The author thinks the operation was unsuitable in the first case, but indicated in the second.—*London Med. Record*, June 15, 1881.

Medical Jurisprudence and Toxicology.

A Case of Belladonna-poisoning treated with Pilocarpin.

A correspondent to the *Brit. Med. Journ.*, for April 16, 1881, Mr. NICHOLAS GRATTAN, reports the following case:—

Mrs. M., aged 42, drank by mistake a wineglassful of a liniment at 9 P. M., December 23d, 1880. Fortunately for her, she had had a hearty dinner about four hours before. She discovered her mistake, and took two teaspoonsful of mustard in water, with no effect; walked a short distance into town, purchased an emetic, which she drank, returned home, and felt dizzy, her sight going, and shadows before her eyes. She lost the power of speech, became greatly excited, had convulsions, and vomited slightly, and then lapsed into profound stupor. At 10.45 P M. I saw her for the first time. Her pupils were widely dilated, not acted on by light; her face was swollen, and of a bluish colour, more especially her lower lip, the mucous membrane of which appeared as if it had been blistered; the pulse was imperceptible in one wrist, almost so in the other; respirations 25. I introduced a stomach-tube, pumped in a mustard emetic, and washed out the stomach thoroughly. In half an hour she had vomited freely, and sensibility was slightly returning, but she soon lapsed again into complete stupor. From this time until 2 A. M. she was treated with cold affusion to the head, and flagellation with a wet towel over her heart. At 2 A. M. I heard from my friend Dr. Harvey (who had ordered the liniment for her) that she had taken two ounces and two drachms of belladonna liniment (*P. B.*). There being no marked improvement in her condition I determined to try pilocarpin. This I procured at 3 A. M., and injected subcutaneously one-fifth of a grain every fifteen minutes. After the third dose, there was a decided improvement; consciousness was evidently returning, her countenance became more natural, her pulse could be distinctly felt, and she was able to raise her hands to her mouth and throat. At 3.45 A. M. I administered a fourth dose of one-fifth of a grain. This had an effect on both pupils, which began to contract under the influence of light. She was evidently fast recovering, had a drink of tea and milk, and was able to speak. At 4.30 A. M. she was so far recovered that I thought it safe to leave her, desiring her friends to send for me should she relapse into her former state. When I saw her again at 10 A. M., she had had a refreshing sleep, from which she awoke, saying that she did not remember anything that had occurred. She had had in all four-fifths of a grain of pilocarpin; it appears to act as a direct antidote to the belladonna; it did not cause the least perspiration. She continued to feel slight dizziness for two days, with dilated pupils; but was, in every other respect, quite well. I gave her half a drachm of tincture of opium each night. The third day she had perfectly recovered.

MEDICAL NEWS.

The New Registration Law of Pennsylvania.

An Act "to provide for the Registration of all Practitioners of Medicine and Surgery," after passing the legislature, was signed by Governor Hoyt, June 8, 1881, and is effective at once. The object aimed at by the bill is to secure an authoritative list of practising physicians in each county of the State, which list shall be accessible by the public. It is based upon the registration law of New York. To insure against misapprehension the law requires the deposit of a duly attested copy of each physician's diploma to be deposited at the time of registration, and filed for future reference.

The bill has been carefully prepared, emanating, as it does, from the Committee on Medical Legislation of the State Medical Society; and it is chiefly due to the exertions of Dr. R. L. Sibbett, of Carlisle, the chairman of this committee, that it was finally passed. Its main features are as follows:—

Section I. requires the prothonotary of each county to keep a special book for the registration of physicians, in which also the subsequent death or removal from the county of a physician shall be duly inscribed.

Section II. declares that "every person who shall practise medicine or surgery or any of the branches of medicine or surgery for gain, or shall receive or accept for his or her services as a practitioner of medicine or surgery, any fee or reward, directly or indirectly, shall be a graduate of a legally chartered medical college or university having authority to confer the degree of doctor of medicine (except as provided for in section 5 of this Act), and such person shall present to the prothonotary of the county in which he or she resides or sojourns his or her medical diploma as well as a true copy of the same including any endorsements thereon, and shall make affidavit before him that the diploma and endorsements are genuine; thereupon the prothonotary shall enter the following in the register, to wit: The name in full of the practitioner, his or her place of nativity, his or her place of residence, the name of the college or university that has conferred the degree of doctor of medicine, the year when such degree was conferred, and in like manner any other degree or degrees that the practitioner may desire to place on record, to all of which the practitioner shall likewise make affidavit before the prothonotary; and the prothonotary shall place the copy of such diploma, including the endorsements, on file in his office for inspection by the public."

Sections III. and IV. provide that in case of the loss of a diploma a

certified copy may be deposited, and in the case of a person commencing practice in this State after the passage of this act, who holds a foreign diploma, that the same shall be countersigned by the dean of one of the medical colleges of this Commonwealth, the faculty of said college, first "being satisfied as to the qualifications of the applicant and the genuineness of the diploma."

Section V. especially exempts those who have practised medicine without a diploma since 1871 from the penalties of the act, provided they make oath to this fact, and record it upon the register.

Section VI. establishes the registration fee at one dollar.

Registration in order to be efficient requires the active co-operation of physicians, and due provision should also be made for the publication in the daily papers once or twice a year, of an authoritative list of qualified practitioners with their place of graduation, if they have any, if not, let this fact likewise be stated.

It is to be regretted, that there was a misunderstanding among some of our principal physicians in regard to the bill for creating a State Board of Health, an important function of which would have consisted in carrying out the provisions of this law in regard to the practice of medicine. As the registration law is framed, it is left to some voluntary informer to prosecute non-registered physicians who are engaged in practice, as a reward he shall receive one half the fine ($100), and in the discretion of the court also half of the penalty (a year in prison), at least, so the law reads, owing to faulty construction of Section VII.

As all properly qualified physicians are interested in the success of measures tending to protect the public from ignorance, incompetence, and imposture, it devolves upon them to aid in making the law effective, by having a committee appointed in each county medical society, which will have the duty, and the courage to perform it, of prosecuting violators of the law. In the absence of a properly constituted State Board of Health this responsibility obviously rests upon the county societies. Should this duty not be performed, it is feared that the law will be a dead-letter. Physicians having urged the passage of this act, the community looks to them to take measures for its enforcement.

Annual Meeting of the American Surgical Association.—The American Surgical Association will hold its first regular meeting at the Oriental Hotel, Coney Island, September 13, 14, and 15. Papers are promised by several gentlemen.

Health of New York.—The advent of the heated term, always so prejudicial to infantile life, has caused a notable increase in the city's mortality during the last month. While the advent of the low temperature, which prevailed during the first weeks of June, was manifest in a reduced death-rate, viz., 660 for the week ending June 4, and 633 for that ending June 11; the figures for the following weeks are as follows: June 19, 637; June 26, 699; July 3, 906; and July 10 it reached 1144.

The Board of Health has taken measures to avert this excessive great mortality from preventible disease, by appointing a corps of 50 tenement-house physicians, whose term of service will extend over five weeks. The corps, which commenced its duties on July 13, will visit every city tenement, at sufficiently frequent intervals, to examine into the health of the inmates and prescribe for the sick. The Board of Estimate and Apportionment has appropriated $30,000 for the salaries of special inspectors, physicians, and nurses, who will be appointed by the Board of Health to aid in combating contagious diseases.

It is noticed that typhus fever has perceptibly diminished during June. During the 12th week of the endemic (ending June 4) there were reported 32 new cases; in the 13th week, 37; in the 14th week, 16; and in the 15th week (ending June 25), 16. The total number of cases for May having been 125, and that for June 101, a reduction of 24 is seen to have taken place. Smallpox has, also, diminished. While 210 cases occurred in May, only 187 were reported in June. Of these 16 were discovered among newly-arrived English and Swedish emigrants. Several new cases developed in Brooklyn, and the disease also appeared in Newark, N. J.

Diphtheria is the only contagious disease which has not decreased during the last month. While there were 410 cases of this disease in May, 434 occurred in June. The number of scarlatina cases has fallen from 636, in May, to 435 in June; and rubeola from 587, in the former, to 430 in the latter month. German measles has diminished since the advent of the warmer weather. Eight cases of isolation were reported on June 29, 23 on July 7, 5 on July 8, and 6 on July 13.

—

The New York City Death-rate.—The reconstructed street-cleaning department is conducting its business with commendable thoroughness and dispatch, but the nuisances at Hunter's Point are still unabated. At a meeting of the Medical Society of the County of New York, held June 27, the chairman of the Committee on Hygiene stated that the death-rate of this city is the largest in the world, even exceeding that of London.

—

Honours to Professor Flint.—The degree of LL.D. was conferred upon Dr. Austin Flint, Sr., by Yale College, at its recent commencement. Dr. Flint is in Europe, whence he will return on September 1.

—

Chair of Gynæcology at the College of Physicians and Surgeons, N. Y.—Dr. T. G. Thomas has resigned the chair of Gynæcology at the College of Physicians and Surgeons, N. Y. City, and Dr. Paul F. Mundé has been appointed Clinical Lecturer on Gynæcology, for one year, at that institution.

—

Presentation to Dr. Shrady.—At a meeting of the New York Pathological Society, held on June 22, 1881, the members of the Society presented Dr. Geo. F. Shrady a massive silver pitcher and salver in token of their appreciation of his services as secretary. The presentation speech was made by Dr. A. Jacobi.

—

The New York Medical Mission.—The New York Medical Mission is the title of a religious and medical charity recently established in New York City. Its rooms at No. 5 East Broadway were formally opened on June 27. The opening exercises, which were conducted by Dr. C. A. Agnew, were largely attended by the poor people of the vicinity. A free dispensary, for the sick poor, will be attached to the institution, and a Gospel service will be held daily. The circulars of the mission state that "no recommendation will be required from patients other than that

they are sick and poor." The circular also states that no fees will be exacted for medical treatment, although remuneration will be expected from such patients as are able to pay.

Patients whose complaints are so serious as to prevent them from attending the dispensary will be treated at their homes. The Board of Managers includes Mr. C. Vanderbilt, Dr. F. H. Markoe, and Dr. S. B. Bangs.

—

Practical Philanthropy.—A summer resort for young workingwomen has been recently opened at Atlanticville, near Long Branch, N. J. The establishment accommodates fifty guests at a time, is situated on the seashore, and has a private beach for surf-bathing. The terms are five dollars for one week, or ten dollars for two weeks, and the sojourn of each guest will be limited to the latter period, in order that the advantages of the institution may be extended to the largest possible number. Mrs. Fletcher Harper, Jr., is one of the leading managers.

—

Institution for the Care of Infants and Young Children in New York.—The New York Society for the Care of Infants and Young Children has established its temporary asylum at the corner of University Place and Ninth Street. The asylum has accommodations for one hundred and fifty children. The circular of the institution states that the plan of the society also embraces the establishment, at as early a period as practicable, of day nurseries in the most populous parts of the city, capable of receiving hundreds of poor children whose mothers are obliged to leave them, during the day, to gain a livelihood at a distance from their homes. The children admitted to the asylum are required to be under the age of three years, and of legitimate birth. A medical attendant resides at the institution, and daily visits are made by the members of the attending medical board.

—

Sanitarium for Children at Mott Haven, N. Y.—A free sanitarium for poor children has been opened in connection with the Old Men's Unsectarian Home at Mott Haven, N. Y.

—

The Working of the Registration Law in New York.—On July 2d two medical practitioners were charged, at the Jefferson Market Police Court, by Dr. A. E. M. Purdy, President of the New York County Medical Society, with practising without a license. In default of bail, these unqualified practitioners were held for trial.

—

Summer Home for Children at Bath, L. I.—The "Summer Home" of the Children's Aid Society, at Bath, L. I., was formally opened on July 8, 1881. The home has, however, been occupied since June 18. It was purchased, together with several smaller buildings, and presented to the Children's Aid Society by Mr. A. B. Stone. The institution will accommodate about two hundred inmates. The children, who come from various tenement districts, are taken to the home in companies of two hundred, and return to the city at the end of a week to make room for the same number of new-comers. Nearly one thousand children have already visited the home this season.

—

Commencement Long Island College Hospital.—The twenty-second commencement of the Long Island College Hospital was held in the Brooklyn Academy of Music on June 14 The graduating class contained fifty-one members. The alumni of the college held their first annual dinner at Coney Island on the preceding evening.

River and Seaside Trips for Poor Children.—The floating hospital of St. John's Guild, of New York, has been thoroughly repaired, and will make three regular weekly trips during the heated season. Tickets can be obtained for the sick children of the poor and their attendants at all the city dispensaries and of physicians. The most usual excursion routes of the floating hospital are up the Hudson, into Long Island Sound, or through the lower bay. Those children in need of treatment at a regular hospital will be transferred to the seaside nursery at Cedar Grove, Staten Island, which is under the direction of the St. John's Guild.

—

Adulteration of Food and Drugs.—At a special meeting of the New York State Board of Health held on June 23d, the duties imposed upon the board by recent legislation were considered. The act to prevent the adulteration of drugs and food was discussed, and it was decided to engage competent chemists to analyze suspicious samples.

—

The thirty-second annual session of the Medical Association of Georgia was held in Thomasville on April 20th and 21st, 1881. The following are the officers for the ensuing year; President, William F. Holt, Macon; First Vice-President, Eugene Foster, Augusta; Second Vice-President, T. M. McIntosh, Thomasville; Secretary, A. Sibley Campbell, Augusta; Treasurer, K. P. Moore, Forsyth. The next session will be held in Atlanta, on the third Wednesday in April (19th), 1882.

—

The New Hampshire Medical Society held its ninety-first annual meeting in Concord, on Tuesday and Wednesday, June 21 and 22. A large and enthusiastic meeting assembled, and the following officers were elected for the ensuing year: President, Dr. H. B. Fowler, Bristol; Vice-President, Dr. A. H. Crosby, Concord; Treasurer, Dr. D. S. Adams, Manchester; Secretary, Dr. G. P. Conn, Concord. Executive Committee, Drs. J. W. Parsons, Portsmouth; P. A. Stackpole, Dover; and M. W. Russell, Concord. Anniversary Chairman, C. A. Tufts, M.D., Dover; and a Council of twenty members. The next semi-annual meeting will occur in September, at the "Wentworth," a famous watering-place near Portsmouth; and the next annual meeting will be in Concord, on the third Tuesday in June, 1882.

—

Injection Brou.—The following is believed to be the formula of the much-vaunted gonorrhœal injection of this name, taken from the register in the French public office: ℞. Zinc. sulph. gr. viij; plumbi acet. gr. xv; tinct. catechu, ʒj; tinct. opii, aqua, āā ʒiij.

—

Change in the Manner of Publication of the Transactions of the Ohio State Medical Society.—By a resolution of the Ohio State Medical Society, its proceedings now appear in the new *Ohio Medical Journal*, of which Vol. I., No. 1, has just appeared. As the journal of the Ohio State Medical Society, it takes the place of the usual volume of *Transactions*, and will be issued monthly, being in reality the successor of the *Ohio Medical Recorder*, which no longer exists. The Editor-in-chief is the Secretary of the Society, Dr. J. F. Baldwin, of Columbus, who is assisted by four Associate Editors: Dr. J. H. Lowman, of Cleveland; Dr. T. C. Minor, of Cincinnati; Dr. Geo. A. Collamore, of Toledo; and Dr. W. J. Conklin, of Dayton. Ohio thus becomes the first State to take the new departure in issuing its proceedings, and, as one result, the papers pre-

sented get a circulation of three thousand copies, instead of less than five hundred, as under the old method.

—

The Kansas State Medical Society held its fifteenth annual session at Topeka, May 10, Dr. B. E. Fryer, of Ft. Leavenworth, President, in the chair. The following officers were elected for the ensuing year: President, Dr. J. H. Stuart of Lawrence; Vice-Presidents, Drs. G. W. Haldeman of Paoli, and F. M. Guibor of Beloit; Secretary, Dr. F. D. Morse of Lawrence. The next meeting will be held at Emporia, on the second Tuesday in May, 1882.

—

Ergot in the Treatment of Sea-sickness.—Dr. T. S. Hopkins of Thomasville, Ga., writes very enthusiastically in regard to the value of ergot for the relief of sea-sickness, from personal experience, in a passage from Savannah to Philadelphia. He considers the following formula as preventive as well as curative. ℞. Ext. ergot fld. (Squibb's) f℥ss; potass. bromid. ℥ss; aquam ad ℥vj.—M. Dose, a tablespoonful two or three times a day.

—

Death from Chloroform(?)—Dr. O. B. Mayer, Jr., of Newbury, S. C., reports the following case of death during the administration of chloroform.

The chloroform was administered for the purpose of extracting a bullet from the hand, on June 13, 1881.

The patient, coloured, age 45 years, was an habitual drunkard, though rarely, if ever, sick, and appeared to be in good health. He had abstained from food and drink for twelve hours. When the chloroform was administered, the patient who had just arrived at the stage of excitement, was seized with an epileptiform convulsion, with marked opisthotonos. He was immediately turned on his side and artificial respiration commenced; stimulants were hypodermically administered, and the patient's head kept lowered. At no time was any evidence of returning life seen. The man died during the fit. He was not subject to epilepsy. A few weeks previously chloroform had been administered to a lady from the same phial successfully, though under its effects for thirty minutes. No autopsy was made.

—

Seaweed as a Substitute for Jam.—Among the few serious political papers published in Paris, we note that the *Temps* occasionally renders good service by describing, in popular language, frauds that gravely compromise public health. Thus on the subject of jellies we have some startling disclosures. We should remark that in France fruit preserves are generally sold as jellies, and not as jam, in which the seed, stones, and sometimes the outline or skin of the fruit itself can be discerned. Falsification is, therefore, more easy. For this purpose gelatine made from fish naturally suggested itself, but was found too expensive. Of late years, however, since the importation on such a large scale of Chinese and Japanese porcelain, etc., a new solution has been found to the problem. The objects imported are generally packed with a common maritime plant that is used instead of straw. This seaweed possesses, however, peculiar properties. When placed in a tumbler of water, it absorbs the water in a few minutes; then a number of shoots grow, and constitute a jelly nearly as transparent as the water from which it is made. This plant, the Arachnoïdiscus japonicus, only costs the trouble of bringing it over. The jelly it yields is easily sweetened with glucose, and cochineal or other colouring matter is added with equal facility to imitate the colour of the fruit. The perfume and the taste were the only real difficulties that remained to be overcome. After considerable study it was discovered that by mixing

our parts of acetic ether and tartaric acid with four parts of glycerine and one part f aldehyde, formic ether, benzoic, butyric, butyric amyl, acetic, œnanthylic, ethyl-salicylic, nitrous, reberythric, and succinic, a perfect imitation of the odour f raspberries was produced. By putting a little of this essence to the seaweed hich has been allowed to develop itself in water, a substance is obtained which as the consistence of fruit jelly, though no fruit has been used, which is sweet, ough no sugar has been employed, and which has the colour and fragrance of aspberries, though altogether destitute of that fruit. When this ceases to please, nother very good fruit flavor is produced by treating castor oil with nitric acid ! ortunately, though wonders are wrought with the Arachnoïdiscus japonicus, the esult is not absolutely perfect. The jelly still retains a little of the fibrous na- re of the plant, and has a tendency to split and fall to pieces, instead of forming dhesive lumps. Examined with the microscope, it has no resemblance to the lly made from fruit. Then, as the jelly must be coloured, it is easy enough to scover the presence of an artificial dye. Without resorting to the laboratory, suffices to dissolve a little of the suspected jelly in some tepid water, and dip white silk ribbon in the solution. If it is a natural jelly, the ribbon will simply e a little soiled; but if the jelly has been artificially coloured, the ribbon will so be coloured. By giving publicity to all these details, the frauds practised ill be constantly discovered, and the perpetrators brought to justice. We fear so that the falsifications the French have contrived, the English will not be ow to imitate, unless it is generally known that the public are on the *qui vive*.—*ancet*, Dec. 11, 1880.

—

The Rest.—A charitable institution, known as the "Rest," was founded, in nuary, 1881, at No. 4 Winthrop Place. Its object is the care of convalescent en who have been recently discharged from the city hospitals, but who are not fficiently strong to undertake their usual occupations. The institution is der the management of the Sisters of the Stranger.

—

Removal of a Hypertrophied Spleen.—In even these days of "heroic" opera- ons, it is very questionable whether the following operation reported in the *Gaz. ed. Lombardia* of April 9 can be justified: "Dr. Chiarleoni performed at e Casa di Salute, Milan, on March 26, splenectomy on a female patient suffer- g from paludal cachexia, in the presence of a large number of distinguished lleagues. The operation, executed with great method and freedom, was very oorious, owing to the extensive and strong adhesions of the spleen to the left ge of the liver and the diaphragm. It was impossible to tie all these adhesions fore removing them, and a very considerable hemorrhage from the surface (*a ppo*) ensued, and this, conjoined with a certain amount of nervous exhaustion, used the woman's death a few hours after the termination of the operation. As r as we are aware, so bold an operation has not been executed in Italy, except n one occasion by Drs. Zaccharelli and Fioravanti, at Naples, in 1549.—*Med imes and Gazette*, April 23, 1881.

—

Ultimate Effects of Tracheotomy.—In a note read at the Academy of Medi- ne (*Bulletin*, April 5), Dr. MONGEOT drew attention to the ultimately fatal sults of tracheotomy. He had for a long time investigated the subject, and ad come to the conclusion that children who had successfully undergone trache- omy, and had worn a canula for a more or less prolonged period, did not live to tain their majority. He had long made inquiries among a great number of

practitioners, and had only succeeded in discovering five or six adults who had undergone this operation in their infancy; while military surgeons, interrogated for more than twenty years past, all avowed that in examining conscripts they had never met with the scar characteristic of tracheotomy. He suggests further investigations on the subject by the military boards of Paris, seeing that the operation is performed about thirty-five times annually on hospital children. He also refers to Dr. Martin's proposal to cease the employment of metallic canulæ. —*Med. Times and Gazette*, April 23, 1881.

—

Statistics of Colour-Blindness.—The report of a Committee appointed by the Ophthalmological Society of the United Kingdom (*Lancet*, April 23, 1881) to collect statistics of cases of colour-blindness presents many features of special interest. The secretary of the Committee, Dr. Brailey, with the assistance of sixteen colleagues, has examined 18,088 persons of all classes, of whom 1657 were females. It is at once curious and suggestive to find that while the average percentage of colour defects among men is 4.76 and 3.5 for very pronounced defects, it falls in women to the low figure of 0.4. This, if true, would seem to suggest a new sphere of labor for women. If women are comparatively free from colour-blindness, they are so far specially indicated for many of the less laborious occupations in which good colour-perception is desirable or absolutely indispensable.

—

Recent Health Legislation.—The New York Senate has passed a bill conferring upon the city health board the power of quarantining any building in New York City, which is used as a dwelling, when such a course seems necessary to prevent the dissemination of any contagious disease.

The New York Legislature has passed a bill for the prevention of the adulteration of food and drugs, which makes it a misdemeanor liable to punishment with a fine of $50, for the first and of $100 for the second offence, to sell any food or drugs adulterated within the meaning of the bill. The adulterations included within the meaning of the act are carefully classified, and the terms "drug" and "food" are stated to comprise every article used by man as food or drink as well as all medicines, whether for external or internal use.

—

Training-school for Nurses.—A new training-school for nurses in connection with Mount Sinai Hospital, has recently been opened at 852 Lexington Avenue, in convenient proximity to the hospital. One of the graduates of the Bellevue Hospital Training-school is the superintendent of the new school which numbers four trained head nurses and eight assistant nurses. The course of training covers two years' time.

—

Manufacture of Quinia.—A patent for the manufacture of quinia from coal tar has been applied for by a prominent drug house.

—

An Action for Malpraxis in Belgium.—The *Presse Médicale Belge* (April 24) refers to an action brought by the children of a person who had died after the injection of five milligrammes of morphia for the relief of severe pain. The experts called proved that the accusation (brought, it is said, at the instigation of a rival practitioner) was wholly groundless, the individual having in reality died from the natural results of organic disease. The tribunal not only acquitted the accused, but adjudged the persons who brought the accusation to pay 1000 fr.

damages to him. If this latter action were followed up in other countries these unfounded accusations would soon diminish.—*Med. Times and Gazette*, May 7, 1881.

—

Professor Billroth's Fourth Case of Resection of the Stomach.—We learn from the *Wiener Medizinische Wochenschrift*, No. 22, that Prof. BILLROTH'S patient, on whom he performed excision of the pylorus for cancer on January 29, has just died in Vienna. The case, surgically speaking, has become historical, for the operation was quite a new departure, and one which, but a short time ago, would have been considered impracticable. The case is rendered more interesting by the fact that an autopsy was obtained, and that thus the condition of parts post mortem has been accurately studied. Dr. Zemann—in the absence of Heschl, the Director of the Pathological Institute, whose death from the effects of a post-mortem wound has since occurred—conducted the examination. He found that death had resulted from metastatic deposits of cancer throughout the entire peritoneum, the duodenum and jejunum being likewise coated with a similar deposit, so that it was impossible to separate them one from another. As regards the stomach, it is stated that it retains its natural form, and that no one unacquainted with the operation to which it had been subjected would have observed anything remarkable about it, or guessed that fourteen centimetres had been removed from it." The duodenum had been attached to its lesser curvature, so that a little pouching was observable along the greater curvature. The woman had not suffered from any digestive troubles, but had taken and retained her food very well. At the point of junction there was no stenosis, the thumb being easily passed through the orifice. The union was perfect in all respects, so that hardly any scar could be perceived along the line of the suture.—*Med. Times and Gazette*, June 4, 1881.

—

Death of Professor Skoda.—The cable announces the death of Dr. JOSEF SKODA, the distinguished Vienna professor, on June 13, 1881. He was born at Pilsen, Bohemia, December 10, 1805, graduated at the Vienna medical schools in 1831, distinguished himself in Bohemia during the cholera epidemic of 1832–33, became in the latter year second physician to the general hospital at Vienna, and became successively physician for the division of lung diseases (1840), chief physician of the hospital (1841), professor of clinical medicine (1846), and a member of the Vienna Academy of Sciences in 1848. Professor Skoda was one of the first to popularize the use of the stethoscope of Laennec, was a great authority on pathological anatomy and on the new methods of auscultation and percussion. His chief work was a "Treatise on Auscultation and Percussion" (1839, sixth edition, 1864).

—

Letter from Prof. Chaillé.

New Orleans, La., July 5th, 1881.

MR. EDITOR.

Dear Sir: Your Journals for July contain two statements in reference to my duties as the representative in New Orleans of the National Board of Health, which deserve correction.

I. The MEDICAL NEWS p. 442, states that "The Louisiana State Board of Health, at its meeting of May 19th, adopted the report of Dr. Formento, which was based upon these instructions [National Board of Health] to Dr. Chaillé, and which renders them *nugatory in almost every particular*, so far as the co-operation of the Board is concerned." A more careful reading of the instruc-

tions on the one hand, and of the report on the other will show that, practically and in all essential particulars, the former were not rendered nugatory in any particular, *except in the single one* referring to the Ship Island Quarantine. A copy is inclosed of my reply to the report on this subject.[1]

II. The *American Journal of the Medical Sciences*, p. 240, referring to the unfortunate disagreement last year, respecting the diagnosis of certain alleged cases of yellow fever, states that "This unfortunate dispute has already been referred to in our columns, and we would therefore simply remark here, that the obvious lesson from its occurrence is in the future to secure so prompt and thorough an investigation, by representatives of all parties interested, of any 'suspicious cases,' that either there shall be no doubt as to their nature, or *the party in error shall be conclusively condemned by the whole country on the evidence of subsequent events.*" If the last clause, italicized, means anything, it must signify that in the writer's opinion, cases of veritable yellow fever must be followed by other cases of the same disease; for, no other subsequent event, except the presence or absence of subsequent cases could have any bearing on the issue. It is surprising to me, that any writer in a journal of such authority as the *American Journal of the Medical Sciences* should display so little knowledge of the history of sporadic cases of yellow fever in all of its noted habitats. In this city as elsewhere, one case alone, or several widely separated cases of *undoubted* yellow fever have repeatedly occurred, without being followed by any "subsequent events" whatever. Therefore, "the conclusive condemnation by the whole country" of a diagnosis of yellow fever, because followed by no subsequent events, would be an outrage upon medical and upon sanitary science. It is painful that your journal should be the instrument of teaching "the whole country" any such false and mischievous lesson, and it is hoped that you will have this error corrected.

Yours very truly, STANFORD E. CHAILLÉ, M.D.

[We gladly publish Dr. Chaillé's communication in deference to his wishes and to prevent any possible misunderstanding by others. It must be evident, however, to any one who has read the latter statement referred to, that it does not have the application that our correspondent has drawn from it, certainly no one would be so rash as to condemn the whole country on the negative evidence quoted in illustration; but where suspicious cases *are* followed by cases of veritable yellow fever the responsibility rests upon the physicians in charge of the early cases of not having made a correct diagnosis or of concealing it. In doubtful cases it is incumbent upon those in charge to take all the means required of securing full investigation and consultation in order that their true character may be brought out, and if the cases by some called "rice-fever," and others "bilious malarial" fever are found to be yellow fever, the proper authorities may then be promptly notified as in other epidemic diseases. If the sentence referred to by Dr. Chaillé means anything at all, it means this, in our opinion.
ED. MED. NEWS AND ABSTRACT.]

To Readers and Correspondents.—The Editor will be happy to receive early intelligence of local events of general medical interest, or which it is desirable to bring to the notice of the profession. Local papers containing reports or news items should be marked.

[1] Pamphlet inclosed entitled "Eadsport, Ship Island Quarantine and the National Board of Health." Reprint from the *New Orleans Democrat*, June 9, 1881. This is an open letter to the Louisiana State Board of Health, by Dr. S. E. Chaillé, in which he ably defends the legality, expediency, and efficiency of the Ship Island Quarantine. —ED. MED. NEWS AND ABSTRACT.

MEDICAL ELECTRICITY:

A PRACTICAL TREATISE ON THE APPLICATION OF ELECTRICITY TO MEDICINE AND SURGERY.

BY

ROBERTS BARTHOLOW, A.M., M.D., LL.D.

In one very handsome octavo volume of 262 pages, with ninety-six illustrations. Printed on Laid Paper.

Price, in cloth binding, $2.50.

MEDICAL ELECTRICITY:

A PRACTICAL TREATISE

ON THE

APPLICATIONS OF ELECTRICITY TO MEDICINE AND SURGERY.

BY

ROBERTS BARTHOLOW, A.M., M.D., LL.D.,

PROFESSOR OF MATERIA MEDICA AND GENERAL THERAPEUTICS IN THE JEFFERSON MEDICAL COLLEGE OF PHILADELPHIA;
FELLOW OF THE COLLEGE OF PHYSICIANS OF PHILADELPHIA;
MEMBER OF THE AMERICAN PHILOSOPHICAL SOCIETY;
HONORARY MEMBER OF THE MEDICAL AND CHIRURGICAL FACULTY OF MARYLAND, OF THE OHIO STATE MEDICAL SOCIETY, OF THE CINCINNATI ACADEMY OF MEDICINE, AND OF THE NEW YORK NEUROLOGICAL SOCIETY;
PRESIDENT OF THE AMERICAN NEUROLOGICAL ASSOCIATION;
AUTHOR OF "A PRACTICAL TREATISE ON MATERIA MEDICA AND THERAPEUTICS," AND OF "A TREATISE ON THE PRACTICE OF MEDICINE," ETC.

WITH NINETY-SIX ILLUSTRATIONS.

PHILADELPHIA:
HENRY C. LEA'S SON & CO.
1881.

PREFACE.

In my annual course of Lectures on Materia Medica and Therapeutics, I have discussed, more or less fully, the subject of electricity as a therapeutical agent. It happened in this way that my attention was called to the need of a suitable text-book. That there are excellent works on medical electricity is undeniable; but some of them are too voluminous, others too scientific, and not a few wanting both in fulness and in accuracy. I have attempted in the preparation of this work to avoid these errors; to prepare one so simple in statement, that a student without previous acquaintance with the subject may readily master the essentials; so complete as to embrace the whole subject of medical electricity, and so condensed as to be contained in a moderate compass. I have endeavored to keep constantly in view, the needs of the two classes for whom the work is prepared—students and practitioners. I have assumed an entire unacquaintance with the elements of the subject as the point of departure—for I am addressing those who have either failed to acquire this preliminary knowledge, or having acquired it, find that after the lapse of years it has become misty and confused.

In the account of electrical phenomena, I have adhered to the modes of expression with which the medical electrical text-books have made us familiar. The time has not come, it seems to me, to adopt the terms and explanations now employed by practical electricians: it is a transition period in which both the old and the new should have a measure of recognition. I have, accordingly, followed the usual course in the account of electrical principles and instruments, introducing also the new terms—the units—by which the electro-motive force, quantity, capacity, and resistance are expressed. Electricity as applied to practical arts—to lighting, heating, telegraphy, and mechanical work generally—demands

different treatment, especially as respects the means and methods of exact measurement, from that required in the presentation of its medical uses. Although it is true that exacter methods of stating current strength, resistances, etc., are desirable in the medical applications of electricity, we are not yet in a position to avail us of the results achieved in the applied science, for the human body is an altogether more uncertain quantity than a copper wire of given length and sectional area. Furthermore, a proper statement of the various questions in the electrical science of to-day, requires the use of the higher algebra and the calculus —an amount of mathematical knowledge not universally possessed by medical students and practitioners. I have, however, entered somewhat into the consideration of the polar method, especially as developed by Erb and Brenner, and have described the mode in which the reactions are now expressed. An entirely novel subject is the adaptation of the Toepler-Holtz electrical machine, by simply connecting the interior and outer coating of the condensers, for the production of nerve and muscle reactions just like those of the primary faradic current. I know of no publication in which this novel fact has been stated.[1] It accordingly opens up for the first time an important field for future investigation and research.

This book, then, must be regarded as the exposition of electricity for remedial purposes, made by a medical practitioner for the use of other medical practitioners. No claim is made on the ground of pure science. It is believed, however, that the work makes an adequate presentation of the subject, regarding electricity as a remedial agent—as one of the means employed for the treatment and cure of disease.

ROBERTS BARTHOLOW.

PHILADELPHIA,
1509 Walnut Street, March, 1881.

[1] As this work is going through the press, my attention is called to a paper by Dr. W. J. Morton in the New York Medical Record for April 9.

CONTENTS.

INTRODUCTION—Modes of the force—Medical electricity . 17

PART I.

ELECTRO-PHYSICS.

CHAPTER I.

MAGNETISM.

Magnets, Natural and Artificial—Lode-stone—North polarity—South polarity—Law of polarity—Magnetic bodies—Diamagnetic bodies—Magnetic induction—Forms of magnets—Coercitive force 19–24

CHAPTER II.

STATIC ELECTRICITY.

Vitreous—Resinous—Theory of Dufay—Conductors—Insulators—Induction—Electrical machines—Leyden jar—Battery of Leyden jars 26–31

CHAPTER III.

DYNAMICAL ELECTRICITY.

Galvanism—Voltaic electricity; Galvanic element; Generating plate; Conducting plate—Conjunctive wire—Galvanometer; Astatic—Positive and negative currents—Volume of the current—Direction of the current—Intensity—Resistance—Ohm's law—Measures of capacity—Electrical discharge—Electrolysis—Anode—Cathode—Anions—Cations 32–40

CHAPTER IV.

FORMS OF GALVANIC COMBINATIONS.

Single fluid battery—Smee's element—Grenet's element—Stöhrer's battery—Grove's Battery—Daniell's Battery—Siemens and Halske's battery—Hill's gravity battery—Leclanché element—Permanent batteries—Portable batteries—Key or pole board—Resistance coils—Cabinet battery—Remak's battery 41–54

CHAPTER V.

ELECTRO-MAGNETISM.

Oersted's discovery—Faraday's discovery—Induction—Ruhmkorff coil—Faradic battery; The couplet; The coil; The interrupter 56–61

CHAPTER VI.

MAGNETO-ELECTRICITY.

The magnet—The coil—The dynamo 64–67

CHAPTER VII.

ELECTRO-MAGNETIC AND MAGNETO-ELECTRIC BATTERIES FOR MEDICAL USE.

Kidder's battery—Flemming's battery—Hall's battery—Gaiffée battery—Combination battery 69–72

CHAPTER VIII.

CARE OF BATTERIES, GALVANIC AND FARADIC: MANIPULATION.

The poles—Moistened electrodes—Dry electrodes—Stabile and labile—Direct or descending—Inverse or ascending—General electrization — Electric bath — Diffusion — Derived currents 76–80

PART II.

ELECTRO-PHYSIOLOGY.

CHAPTER I.

ANIMAL ELECTRICITY.

Electric eel—Muscle currents—Nerve currents—Electrotonic state—Electro-capillarity 81–85

CHAPTER II.

ACTION OF THE GALVANIC CURRENT ON MOTOR, SENSORY, AND MIXED NERVES.

Muscular irritability—Muscle and nerve preparation—Muscle curve—Descending currents—Ascending currents — Electrotonus—Anelectrotonic—Catelectrotonic—Induced contractions 89–94

CHAPTER III.

ACTION OF INDUCED OR FARADIC CURRENTS ON MOTOR, SENSORY, AND MIXED NERVES . . 95

CHAPTER IV.

ACTION OF GALVANIC AND FARADIC ELECTRICITY ON THE SYMPATHETIC AND VASO-MOTOR SYSTEMS.

Contractions of non-striated muscles — Vermicular contractions 97

CHAPTER V.

ACTION OF GALVANIC AND FARADIC ELECTRICITY ON MUSCLE—STRIATED AND NON-STRIATED.

Galvano-tonic contractions—Action of non-striated . 100–101

CHAPTER VI.

ACTION OF GALVANIC AND FARADIC CURRENTS ON THE CEREBRO-SPINAL AXIS.

Does the current traverse the brain?—Spinal effects . 103–104

CHAPTER VII.

ACTION OF GALVANIC AND FARADIC CURRENTS ON THE PNEUMOGASTRIC NERVE AND HEART . . 105

CHAPTER VIII.

ACTION OF ELECTRICITY ON THE SPECIAL SENSES.

Brenner's formulæ 109

PART III.

ELECTRO-DIAGNOSIS.

CHAPTER I.

ELECTRO-CONTRACTILITY.

Methods—Muscular reactions—Nerve reactions—Spinal reactions—Normal formulæ—Disease formulæ—Reactions of degeneration 111–118

CHAPTER II.

ELECTRO-SENSIBILITY.

Methods—Hysterical paralysis—Feigned affections . 122–124

PART IV.

ELECTRO-THERAPEUTICS.

CHAPTER I.

ELECTRICITY IN CEREBRAL AFFECTIONS.

Cerebral congestion — Cerebral anæmia — Psychical disorders 127–131

CHAPTER II.

ELECTRICITY IN SPASM AND CRAMP.

Epilepsy—Chorea—Histrionic spasm—Blepharospasm—Torticollis—Stricture of œsophagus—Singultus—Spasmodic asthma—Tetanus—Writer's cramp 134–140

CHAPTER III.

ELECTRICITY IN THE PARALYSES.

Spinal paralyses; Paraplegia; Chronic myelitis; Infantile paralysis; Pseudo-hypertrophic; Progressive muscular atrophy; Sclerosis of the cord—Peripheral paralysis; Facial paralysis; Muscular paralysis; Paralysis of ocular muscles—Hysterical paralyses—Diphtheritic paralysis—Lead paralysis . 142–172

CHAPTER IV.

ELECTRICITY IN THE TREATMENT OF PAIN.

Neuralgia of the fifth nerve; Cervico-brachial; Intercostal; Sciatic; Lumbago; Myalgia; Rheumatism—Visceral neuralgia; Hemicrania; Angina pectoris; Gastralgia . . 176–185

CHAPTER V.

ELECTRICITY IN ANÆSTHESIA AND ANALGESIA.

Anosmia—Amblyopia—Amaurosis—Anæsthesia of the auditory nerve 187–188

CHAPTER VI.

ELECTRICITY IN THE VASO-MOTOR AND TROPHIC NEUROSES.

Exophthalmic goitre—Skin diseases—Œdema Ascites . 190–194

CHAPTER VII.

ELECTRICITY IN CONSTITUTIONAL DISEASES.

Syphilitic affections—Chronic rheumatism . . 195–196

CHAPTER VIII.

ELECTRICITY IN LOCAL, OTHER THAN NERVOUS DISEASES.

Naso-pharyngeal—Vomiting—Atonic dyspepsia—Constipation—Impaction of the intestines—Respiratory depression—Cardiac depression—Uterine hemorrhage—Amenorrhœa—Irritability of the bladder—Impotence—Genital irritation—Urethral applications—Electrodes for various uses 199–208

CHAPTER IX.

STATIC ELECTRICITY—ITS THERAPEUTICAL APPLICATIONS.

Holtz machine—The electric bath—Electrization by sparks—Chorea 211–213

PART V.

ELECTRICITY IN SURGERY.

CHAPTER I.

ELECTROLYSIS.

The battery—The needles—Aneurism—Cystic tumors—Polypi—Stricture of the urethra—Fibroid tumors . . 220–229

CHAPTER II.

MEDICAL ELECTRIC LIGHTING AND HEATING.

Electric lamps—Polarization current Plante's cell—Trouvé's polyscope—Reflectors—Galvano-causty—Batteries—Galvano-caustic electrodes—Galvano-caustic loop; Knife; Cautery—Electric larnygoscope 231–247

PART VI.

THERMO-ELECTRICITY.

CHAPTER I.

PRINCIPLES.

Galvanometer—Thermo-electric pile; Multiplier—Lombard's apparatus 250–254

CHAPTER II.

MEDICAL USES OF THE THERMO-ELECTRIC PILE.

Variations of temperature 254

IMPOTENCE, STERILITY,

AND

ALLIED DISORDERS OF THE MALE SEXUAL ORGANS.

By SAMUEL W. GROSS, A.M., M.D.

In one handsome octavo volume of 174 pages, with 16 illustrations.
Printed on Laid Paper.

Price, in cloth binding, $1.50.

A PRACTICAL TREATISE

ON

IMPOTENCE, STERILITY,

AND

ALLIED DISORDERS

OF THE

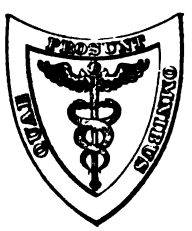
MALE SEXUAL ORGANS.

BY

SAMUEL W. GROSS, A.M., M.D.,

LECTURER ON VENEREAL AND GENITO-URINARY DISEASES IN THE JEFFERSON MEDICAL COLLEGE OF PHILADELPHIA; SURGEON TO, AND LECTURER ON CLINICAL SURGERY IN, THE JEFFERSON MEDICAL COLLEGE HOSPITAL AND THE PHILADELPHIA HOSPITAL; PRESIDENT OF THE PATHOLOGICAL SOCIETY OF PHILADELPHIA; AUTHOR OF A PRACTICAL TREATISE ON TUMORS OF THE MAMMARY GLAND; FELLOW OF, AND FORMERLY MÜTTER LECTURER ON SURGICAL PATHOLOGY IN, THE COLLEGE OF PHYSICIANS OF PHILADELPHIA; FELLOW OF THE ACADEMY OF SURGERY OF PHILADELPHIA, ETC.

WITH SIXTEEN ILLUSTRATIONS.



PHILADELPHIA:
HENRY C. LEA'S SON & CO.
1881.

PREFACE.

Of the affections discussed in this brochure at least two—Impotence and Spermatorrhœa—are commonly described as functional diseases of the testicles; while, according to my observations, they usually depend upon reflex disturbances of the genito-spinal centre, and are almost invariably induced or maintained by appreciable lesions of the prostatic portion of the urethra, which, as they may not be perceived by the patient, are frequently overlooked by the physician. A more extended knowledge of these pathological facts, it is hoped, will afford a more rational and simple basis for treatment.

My aim has been to supply in a compact form practical and strictly scientific information, especially adapted to the wants of the general practitioner, in regard to a class of common and grave disorders, upon the correction of which so much of human happiness depends. In the chapter on Sterility, the abnormal conditions of the semen and the causes which deprive it of its fecundating properties are fully considered—a portion of the work intended to supplement the subject of sterility in the female. From answers to letters addressed to many of the most prominent writers in this country on gynecology, I find that, with few exceptions, the woman alone commands attention in unfruitful marriages. The importance of examining the husband before subjecting the wife to operation will be best appreciated when I state that he is, as a rule, at fault in at least one instance in every six.

S. W. GROSS.

Philadelphia,
1112 Walnut Street, July, 1881.

CONTENTS.

CHAPTER I.

IMPOTENCE.

SECT. I.—General observations—Mechanism of erection . 17–20

SECT. II.—Atonic impotence.

A. Atonic impotence from hyperæsthesia and inflammation of the prostatic urethra—Etiology—Local effects of masturbation—Masturbation a cause of stricture of the urethra—General effects of masturbation — Classification — Clinical history—Neurasthenia—Diagnosis—Prognosis—Local treatment—General treatment 20–58

B. Atonic impotence without hyperæsthesia of the prostatic urethra—Etiology—Treatment 58–59

SECT. III. Psychical impotence.

Etiology—Prognosis—Treatment 59–66

SECT. IV. Symptomatic impotence.

From the prolonged use of cerebral sedatives and cerebral excitants—From injuries of the brain and spinal cord—Prognosis—Treatment 66–68

SECT. V. Organic impotence.

A. Impotence from abnormal conditions of the penis—From malformations of the penis—From variations in the size of the penis—From adhesion of the penis to the scrotum—From distortion of the penis—From induration of the corpora cavernosa — From gummata of the corpora cavernosa — From calcification of the septum pectiniforme, or corpora cavernosa —From retention of a ball in the corpus cavernosum—From shortness of the frenum—From varix of the dorsal vein of the penis 69–77

B. Impotence from defects and disease of the testes—From cryptorchidism—From loss of the testes—From progressive atrophy of the testes—From syphilitic orchitis—From tumors and tubercle 79–80

CHAPTER II.

STERILITY.

SECT. I. General observations.

Composition of the semen—Functions of the prostatic fluid—Spermatozoa—Spermatic crystals—Classification—Relative frequency in the two sexes 81–88

SECT. II. Azoospermism.

From bilateral anorchidism—From congenital bilateral deficiency of the epididymis and vas deferens—From affections of the testes—From bilateral atrophy of the testes—From parenchymatous orchitis and total disorganization of the substance of the testes—From syphilitic orchitis—From bilateral obliteration of the epididymis and vas deferens—From abnormal conditions of the semen—Sexual excesses a cause of infertile semen—Neurasthenia a cause of infertile semen—General diseases a cause of infertile semen—Abnormal density of the semen a cause of sterility—Purulent semen a cause of sterility—Diagnosis—Watery semen—Colloid semen—Catarrhal semen—Prognosis—Treatment 88–114

SECT. III. Aspermatism.

A. Organic aspermatism—From congenital occlusion, and devi. ation of the ejaculatory ducts—From stricture of the ejaculatory ducts, and deviation of their orifices—From obstruction of the ejaculatory canals by sympexions—From stricture of the urethra—From phimosis 114–123

B. Atonic aspermatism—Etiology 123

C. Anæsthetic aspermatism—Etiology . . . 125

D. Psychical aspermatism—Etiology—Diagnosis of asperm atism—Prognosis—Treatment 127

SECT. IV. Misemission.

From vices of conformation of the urethra—From malposition of the meatus—Treatment 132

CHAPTER III.

SPERMATORRHŒA.

Classification—Nocturnal pollutions—Diurnal pollutions—Spermorrhagia—Clinical history—Etiology—Anatomical characters—Diagnosis—Prognosis—Treatment . 134

CHAPTER IV.

PROSTATORRHŒA.

Etiology—Clinical history—Prostatic crystals—Pathological characters—Diagnosis—Prognosis—Treatment . 162

NEW MEDICAL BOOKS.

SMITH ON CHILDREN—New Edition—Nearly Ready.

A COMPLETE PRACTICAL TREATISE ON THE DISEASES OF CHILDREN. By J. LEWIS SMITH, M.D., Clinical Professor of Diseases of Children in the Bellevue Hospital Medical College, New York. Fifth edition, thoroughly revised and rewritten. In one handsome octavo volume of about 800 pages, with illustrations.

The very marked favor with which this work has been received, wherever the English language is spoken, has stimulated the author, in the preparation of the fifth edition, to spare no pains in the endeavor to render it worthy, in every respect, of professional confidence. Many portions of the volume have been rewritten, and much new matter introduced, but by an earnest effort at condensation, the size of the work will not be materially increased.

HARTSHORNE'S ESSENTIALS.—New Edition—In Press.

ESSENTIALS OF THE PRINCIPLES AND PRACTICE OF MEDICINE. A handy-book for Students and Practitioners. By HENRY HARTSHORNE, M.D., Professor of Hygiene in the Univ. of Penna. Fifth edition, thoroughly revised and much improved. With 140 illustrations. In one handsome royal 12mo. volume of about 600 pages.

The very great success which has exhausted four large editions of this work shows that the author has succeeded in supplying a want felt by a large portion of the profession. It has also enabled him in successive revisions to perfect the details of his plan, and to render the work still more worthy of the favor with which it has been received. The present edition has had sedulous attention at the hands of the author to bring it in every way on a level with the most advanced condition of the subject, and no effort has been spared to make the volume worthy a continuance of the very great favor with which it has hitherto been received.

HAMILTON ON NERVOUS DISEASES—New Edition—In Press.

NERVOUS DISEASES; THEIR DESCRIPTION AND TREATMENT. By ALLAN MCLANE HAMILTON, M.D., Attending Physician at the Hospital for Epileptics and Paralytics, Blackwell's Island, N. Y., and at the Out-Patients' Department of the New York Hospital. Second edition, thoroughly revised and rewritten. In one handsome octavo volume of about 600 pages, with numerous illustrations.

FOSTER'S PHYSIOLOGY—New and Revised Edition—In Press.

A TEXT-BOOK OF PHYSIOLOGY. By MICHAEL FOSTER, M.D., F.R.S., Prof. of Physiology in Cambridge Univ., England. Second American, from the third English edition. Edited, with extensive notes and additions, by EDWARD T. REICHERT, M.D., Demonstrator of Experimental Therapeutics in Univ. of Penna. In one handsome royal 12mo. volume of about 1000 pages, with 259 illustrations.

WOODBURY'S HANDBOOK OF PRACTICE—In Press.

A HANDBOOK OF THE PRINCIPLES AND PRACTICE OF MEDICINE. For the use of Students and Practitioners. By FRANK WOODBURY, M.D., Physician to the German Hospital, Philada., late Chief Assistant to the Medical Clinic at Jefferson College, etc. In one neat volume, royal 12mo. With illustrations.

HOLDEN'S LANDMARKS—New Edition—In Press.

LANDMARKS, MEDICAL AND SURGICAL. By LUTHER HOLDEN, F.R.C.S., Surgeon to St. Bartholomew's and the Foundling Hospitals. Second American, from the third English Edition, with additions by W. W. KEEN, M.D., Prof. of Artistic Anatomy in the Penna. Acad. of the Fine Arts; formerly Lecturer on Anatomy in the Phila. School of Anatomy, etc. In one handsome royal 12mo. volume of about 140 pages.

KEATING ON INFANCY—Just Ready.

THE MOTHER'S GUIDE IN THE MANAGEMENT AND FEEDING OF INFANTS. By JOHN M. KEATING, M.D., Lecturer on the Diseases of Children in the Univ. of Penna., etc. In one handsome 12mo. volume of 118 pages. Cloth, $1 00.

GROSS ON DISORDERS OF THE MALE SEXUAL ORGANS—Just Ready.

A PRACTICAL TREATISE ON IMPOTENCE, STERILITY, AND ALLIED DISORDERS OF THE MALE SEXUAL ORGANS. By SAMUEL W. GROSS, A.M., M.D., Lecturer on Genito-Urinary and Venereal Diseases in the Jefferson Medical College, Philada. In one very handsome octavo volume of 174 pages, with 16 illustrations. Cloth, $1 50.

EXTRACT FROM THE AUTHOR'S PREFACE.

"My aim has been to supply, in a compact form, practical and strictly scientific information, especially adapted to the wants of the general practitioner, in regard to a class of common and grave disorders, upon the correction of which so much of human happiness depends. In the chapter on Sterility, the abnormal conditions of the semen and the causes which deprive it of its fecundating properties are fully considered—a portion of the work intended to supplement the subject of sterility in the female. From answers to letters addressed to many of the most prominent writers in this country on gynæcology, I find that, with few exceptions, the woman alone commands attention in unfruitful marriages. The importance of examining the husband before subjecting the wife to operation will be best appreciated when I state that he is, as a rule, at fault in at least one example in every six."

HENRY C. LEA'S SON & CO.—Philadelphia.

PROSPECTUS FOR 1881.

THE AMERICAN JOURNAL OF THE MEDICAL SCIENCES.

In commencing its sixty-first year, the publishers of the "AMERICAN JOURNAL OF THE MEDICAL SCIENCES" have much pleasure in assuring its wide circle of readers that at no period has it had the prospect of a more extended field of usefulness.

For 1881 the "American Journal" has the promise of its usual variety of important contributions from distinguished members of the profession in all parts of the country. Special attention will be bestowed, as heretofore, on its Bibliographical Department and Quarterly Summaries to keep its subscribers informed as to all subjects of professional interest from every quarter.

With its attendant periodical, "THE MEDICAL NEWS AND ABSTRACT," it combines the advantages of the elaborate preparation which can be given to a quarterly, and the prompt conveyance of intelligence by the monthly, while, the whole being under a single editorial supervision, the subscriber is secured against the duplication of matter inevitable under other circumstances. These efforts the publishers seek to second by offering these periodicals at a price unprecedentedly low—a price which places them within the reach of every practitioner, and gives the equivalent of three large octavo volumes for the comparatively trifling cost of FIVE DOLLARS *per annum*.

The "NEWS AND ABSTRACT" consists of sixty-four pages monthly, in a neat cover. It contains a CLINICAL DEPARTMENT in which will be continued the series of ORIGINAL AMERICAN CLINICAL LECTURES, contributed by gentlemen of the highest reputation throughout the United States, together with a choice selection of Foreign Lectures and Hospital Notes and Gleanings. Then follows the "MONTHLY ABSTRACT," systematically arranged and classified, and presenting five or six hundred articles yearly; each number concluding with an EDITORIAL and a NEWS DEPARTMENT, giving current professional intelligence, domestic and foreign, the whole fully indexed at the close of each volume, rendering it of permanent value for reference.

The subscription price to the "NEWS AND ABSTRACT" will be Two Dollars and a Half per annum, invariably in advance, at which rate it will rank as one of the cheapest medical periodicals in the country. But it will also be furnished, free of all charge, in commutation with the "AMERICAN JOURNAL OF THE MEDICAL SCIENCES," to all who remit FIVE DOLLARS in advance, thus giving to the subscriber, for that very moderate sum, a complete record of medical progress throughout the world, in the compass of about two thousand large octavo pages.

These terms may be recapitulated as follows:—

TERMS FOR 1881.

The AMERICAN JOURNAL OF THE MEDICAL SCIENCES, published quarterly (1150 pages per annum), and
The MEDICAL NEWS AND ABSTRACT, published monthly (768 pages per annum),
} **Five Dollars per annum, in advance.**

SEPARATE SUBSCRIPTIONS TO

The AMERICAN JOURNAL OF THE MEDICAL SCIENCES, when not paid for in advance, } **Five Dollars.**
The MEDICAL NEWS AND ABSTRACT, invariably in advance, **Two Dollars and a Half.**

*** Advance-paying subscribers can obtain, at the close of the year, cloth covers, gilt lettered, for binding the volumes of the JOURNAL (two annually) and the NEWS AND ABSTRACT (one annually), free by mail, on remitting ten cents for each cover.

The safest mode of remittance is by bank check or draft, or postal money order drawn to the order of the undersigned. Where these are not accessible, remittances for the "JOURNAL" and "NEWS AND ABSTRACT" may be made at the risk of the publishers by forwarding in REGISTERED letters. Address

AND

ABSTRACT.

EDITED BY

I. MINIS HAYS, A.M., M.D.

PHILADELPHIA:
HENRY C. LEA'S SON & CO.
1881.

PUBLISHED MONTHLY AT $2.50 PER ANNUM IN ADVANCE.
Furnished in conjunction with the Quarterly American Journal of the Medical Sciences (in all nearly 2000 octavo pages) for $5.00 in advance.

Entered according to the Act of Congress, in the year 1881, by HENRY C. LEA'S SON & CO., in the Office of the Librarian of Congress. All rights reserved.

STANDARD MEDICAL TEXT-BOOKS.

ANATOMY.

GRAY'S ANATOMY. Descriptive and Surgical. A new American from the Eighth London edition, to which is added "Holden's Landmarks, Medical and Surgical. In one imperial 8vo. volume of nearly 1000 pages, with 522 illustrations. Cloth, $6; leather, $7; half Russia, raised bands, $7.50.

ELLIS'S DEMONSTRATIONS OF ANATOMY. From the Eighth English edition. In one 8vo. volume of over 700 pages, with 236 illustrations. Cloth, $4.25; leather, $5.25.

WILSON'S SYSTEM OF HUMAN ANATOMY. In one 8vo. volume of over 600 pages, with 397 illustrations. Cloth, $4; leather, $5.

HEATH'S PRACTICAL ANATOMY. Revised by W. W. Keen, M.D. From the Second English edition. In one royal 12mo. volume of 578 pages, with 247 illustrations. Cloth, $3.50; leather, $4.

PHYSIOLOGY.

DALTON'S HUMAN PHYSIOLOGY. Sixth edition. In one handsome 8vo. volume of 830 pages, with 316 illustrations. Cloth, $5.50; leather, $6.50; half Russia, $7.

FOSTER'S PHYSIOLOGY. Second American from latest English edition. Edited by E. T. Reichert, M.D. In one handsome 12mo. volume of about 1000 pages, with 259 illustrations. (*In Press.*)

CARPENTER'S PRINCIPLES OF PHYSIOLOGY. With American additions. From the Eighth English edition. In one 8vo. volume of 1083 pages, with two plates and 373 engravings. Cloth, $5.50; leather, $6.50; half Russia, raised bands, $7.

CHEMISTRY.

ATTFIELD'S CHEMISTRY. General, Medical, and Pharmaceutical. Eighth American edition, revised by the author. In one 12mo. vol. of over 700 pages, with 87 illustrations. Cloth, $2.50; leather, $3.

FOWNES' MANUAL OF ELEMENTARY CHEMISTRY. New American edition. In one large royal 12mo. volume of over 1000 pages, with 177 illustrations. Cloth, $2.75; leather, $3.25

CLOWES' ELEMENTARY PRACTICAL CHEMISTRY AND QUALITATIVE INORGANIC ANALYSIS. Second edition. In one royal 12mo. volume of 372 pages, with 47 illustrations Cloth, $2.50.

BLOXAM'S CHEMISTRY. Inorganic and organic. From the Second English edition. In one handsome 8vo volume of 700 pages, with about 300 illustrations. Cloth, $4; leather, $5.

GREENE'S MEDICAL CHEMISTRY. For the Use of Students. In one royal 12mo. volume of 312 pages, with illustrations. Cloth, $1.75.

THERAPEUTICS AND MATERIA MEDICA.

THE NATIONAL DISPENSATORY. By Alfred Stillé, M.D., and John M. Maisch, Ph.D. Second edition, thoroughly revised. In one handsome octavo volume of 1692 pages, with 239 illustrations. Cloth, $6.75; leather, $7.50; half Russia, raised bands, $8.25.

STILLÉ'S THERAPEUTICS AND MATERIA MEDICA. Fourth edition, thoroughly revised. In two handsome octavo volumes of about 2000 pages. Cloth, $10; leather, $12; half Russia, raised bands, $13.

FARQUHARSON'S THERAPEUTICS AND MATERIA MEDICA. Second American edition. In one royal 12mo. volume of 498 pages. Cloth, $2.25.

PATHOLOGY AND HISTOLOGY.

CORNIL AND RANVIER'S PATHOLOGICAL HISTOLOGY. Translated, with notes and additions, by E. O. Shakespeare, M.D., and J. H. C. Simes, M.D. In one handsome 8vo. volume of over 700 pages, with over 350 illustrations. Cloth, $5.50; leather, $6.50; half Russia, raised bands, $7.

SCHAFER'S PRACTICAL HISTOLOGY. In one 12mo. volume of 304 pages, with illustrations. Cloth, $2.

PRACTICE.

FLINT'S PRINCIPLES AND PRACTICE OF MEDICINE. Fifth edition, entirely rewritten. In one 8vo. volume of 1153 pages. Cloth, $5.50; leather, $6.50; half Russia, raised bands, $7.

REYNOLDS'S SYSTEM OF MEDICINE. With Notes and Additions, by Henry Hartshorne, M.D. In three imperial 8vo volumes of 3052 double-columned pages, with numerous illustrations. Cloth, $15; leather, $18; half Russia, raised bands, $19.50.

BRISTOWE'S PRACTICE OF MEDICINE. Second American edition. In one handsome 8vo. volume of nearly 1200 pages, with illustrations. Cloth, $5; leather, $6; half Russia, raised bands, $6.50.

HARTSHORNE'S ESSENTIALS OF THE PRINCIPLES AND PRACTICE OF MEDICINE. Fifth edition, thoroughly revised and much improved. In one royal 12mo. vol., with 146 illustrations. (*In Press.*)

FOTHERGILL'S HANDBOOK OF TREATMENT. Second edition, revised and enlarged. In one 8vo. volume of about 650 pages. Cloth, $4; half Russia, raised bands, $5.50.

BARTHOLOW'S PRACTICAL TREATISE ON ELECTRICITY IN ITS APPLICATION TO MEDICINE. In one very handsome 8vo. volume of about 270 pages, with 98 illustrations. Cloth, $2.50.

HAMILTON ON NERVOUS DISEASES. Second edition, thoroughly revised and rewritten. In one handsome 8vo. volume of about 600 pages, with numerous illustrations. (*In Press.*)

MORRIS ON SKIN DISEASES. In one 12mo. vol. of over 300 pages, with illustrations. Cloth, $1.75.

WELLS ON DISEASES OF THE EYE. Third American from Third English edition, with additions by Charles S. Bull, M.D. In one handsome octavo volume of 900 pages, with 250 engravings, six colored plates, and test-types of Snellen and Jaeger. Cloth, $5; leather, $6; half Russia, raised bands, $6.50.

NETTLESHIP'S MANUAL OF OPHTHALMIC MEDICINE. In one royal 12mo. volume of over 350 pages, with illustrations. Cloth, $2.

CARTER'S PRACTICAL TREATISE ON DISEASES OF THE EYE. With test-types and additions by John Green, M.D. In one 8vo. volume of about 500 pages, with 124 illustrations. Cloth, $3.75.

BUMSTEAD'S PATHOLOGY AND TREATMENT OF VENEREAL DISEASES. Fourth edition, thoroughly revised and rewritten. In one handsome 8vo. volume of 835 pages, with 135 illustrations. Cloth, $4.75; leather, $5.75; half Russia, raised bands, $6.25.

SMITH'S COMPLETE PRACTICAL TREATISE ON THE DISEASES OF CHILDREN. Fifth edition, thoroughly revised. In one 8vo. volume of 800 pages, with illustrations. (*In Press.*)

HABERSHON ON DISEASES OF THE ABDOMEN. Second American from the Third enlarged and revised English edition. In one handsome 8vo. volume of over 500 pages. Cloth, $3.50.

GROSS ON THE URINARY ORGANS. Third edition. Edited by S. W. Gross, M.D. In one 8vo. volume of 574 pages, with 170 illustrations. Cloth, $4.50.

ROBERTS ON URINARY AND RENAL DISEASES. In one 8vo. volume of over 600 pages. Cloth, $4.

HENRY C. LEA'S SON & CO., Philadelphia.

CLINICS.

Clinical Lectures.

CLINICAL LECTURE ON CATALEPSY; TRICHINOSIS; AND THE TREATMENT OF PNEUMONIA BY BLOOD-LETTING, COLD SPONGING, AND THE WET SHEET.

DELIVERED AT BELLEVUE HOSPITAL, NEW YORK.

BY AUSTIN FLINT, M.D.,
PHYSICIAN TO THE HOSPITAL.

GENTLEMEN: I shall introduce, to-day, several cases exemplifying different diseases, calling your attention, in connection with each case, to points of practical interest.

The first case is interesting as illustrative of a very rare form of disease, so rare that many of you will probably never meet with another example. The patient before you has catalepsy. As you see, she is a young woman, and appears to be tranquilly sleeping. Her eyes are closed. She is pallid, but the face is not cyanotic, and gives no appearance of distress. Her respirations are regular, in rhythm, and not accelerated. I now raise both arms so that they are perpendicular to the trunk. You will perceive that they will remain in this situation as long as the patient is in the amphitheatre. They are not kept in this situation by the volition of the patient. They will remain thus raised longer than would be comfortable, or perhaps practicable, by a sustained effort of the will. This is the symptom characteristic of catalepsy. Other parts of the body placed in positions not easily maintained by volition, continue immovable for a considerable period. There is, therefore, a tonic contraction of voluntary muscles, by which they adapt themselves to different positions of the body or of its parts, this tonic contraction persisting independent of volition. The contraction is easily overcome; the positions of the body or of its parts may be readily changed, very little resistance being offered by rigidity of the muscles. As regards this point different cases differ. Aside from the symptom pertaining to the muscles which constitutes the pathognomonic feature of the cataleptic state, the morbid condition is that of hysterical coma. The coma is not complete. The patient can be aroused sufficiently to open the eyes and to protrude the tongue, but she takes no

notice, and cannot be made to speak. She will not voluntarily take food or drink. It is necessary to nourish her by injecting food into the stomach. This is easily done by means of a tube introduced into the œsophagus through the nose, and Davidson's syringe. In order to illustrate the procedure, Dr. Anderton, the House Physician, will now inject into the stomach several ounces of milk. The patient, as you see, manifests some discomfort, but makes no resistance to the operation. This patient is a woman, but the affection is not confined to women. In the last case which came under my observation the patient was a boy, about 20 years of age, in this hospital.

I will now read the history of the case, as far as it has been ascertained, from the hospital records, as follows :—

"Minnie R., æt. 21, U. S., box-maker, admitted May 17, 1881. No history could be obtained from the patient, as she cannot be made to speak. She lies quietly, apparently paying no attention to events around her. Occasionally she moves her head on the pillow, but maintains her body in a state of perfect repose. The limbs remain in any position in which they may be placed, even though an uncomfortable one and difficult to maintain. When the limbs have been made to assume such positions they will support considerable weights for long periods. The limbs offer no resistance to passive motion, but remain fixed and immobile. Sensation is preserved and its existence betrayed by facial contortions, indicative of pain, when the cutaneous surface is pricked. The reflex movements are preserved. Slight irritation of the skin over the abdomen or thorax causes the patient to smile. When asked to protrude her tongue she does so, but quickly retracts it, as though she had committed an unintentional error in putting it out. The electrical excitability of the muscles and the tendon reflexes are well preserved. The temperature is normal, the pulse 78, and the respirations 20 per minute. The urine is reddish, acid, has a specific gravity of 1017, and contains no albumen.

"The patient refuses to eat, and is fed through a soft rubber catheter which is passed through the nose, and through which fluids are pumped into the œsophagus."

You may ask what is the pathology of this remarkable affection. I cannot give a satisfactory answer to this question. The condition of the patient is one which may be induced in some healthy persons who have a certain peculiar susceptibility of the nervous system. Thus induced, it was formerly included among the phenomena which were embraced under the names mesmerism and animal magnetism. The study of these phenomena within late years has been revived, and the term hypnotism is now applied to this voluntarily induced cataleptic state. The use of a new name is not an explanation, and I do not think that the phenomena can be better explained now than nearly half a century ago. The truth is, our present knowledge of the physiology of the nervous system is not sufficiently advanced to serve as the basis of an explanation of these and various other manifestations of perverted neurotic functions. We have no knowledge of the essential nature of the connection of nervous influences with muscular movements, either voluntary or involuntary, and of the tonic contraction of the muscles. We know not the nature of the agency which emanates from the brain, and is transmitted to the muscles in the exertion of the will. We are equally in the dark as regards the process which takes place within the brain whenever there is an act of volition.

Catalepsy is not an affection involving danger to life. This patient will recover. The first indication in the way of treatment relates to alimentation. Food must be introduced into the stomach until it is taken voluntarily. In order to arouse the mental faculties, "firing" may be resorted to. I shall prescribe this measure in this case. It may be employed by an instrument made for that purpose, but a common hammer dipped in boiling water suffices. It should be applied for an instant at different points over the spine and in other situations. The operation may be repeated two or three times daily. Electricity may also be employed with advantage.[1]

The next case is one of interest as a rare disease, and, also, for the reason that it has existed in the nosology for only a quarter of a century. Owing to its infrequency and the recent date of our knowledge respecting it, there is a liability to mistake it for other diseases; hence, the importance of its diagnostic features. The case is one of Trichinosis, Trichiniasis, or the Trichina disease. For a zoological history of the parasite which causes the disease, and a full account of its symptomatology, I refer you to text-books. I will just read the hospital record of the case, and afterward comment on some practical points.

"Peter Y., æt. 27; Germany; upholsterer; admitted April 15, 1881. The patient states that he ate pork, either raw or only partially cooked, several times during the week preceding March 21st, as also on that day and on the three succeeding days. On March 21st, up to which time he had been in perfect health, he was seized with a sense of oppression in the stomach, and with lancinating abdominal pains. He had also vomiting, which continued at irregular intervals for four days, and diarrhœa which persisted, in spite of domestic remedies, for two weeks. During this time he had occasional exacerbations of fever, most marked in the evening and at night. On April 1st his muscles began to be painful, particularly when they were made to contract, and they were tender on pressure. Deglutition became painful, and he suffered from asthenia and general *malaise*. On admission, April 15, 1881, he was found lying upon his left side with his arms and legs in the position of complete flexion. The thighs were strongly adducted. He moved his extremities without pain as long as they remained considerably flexed, but any attempt at extension occasioned great suffering. The abdomen was sensitive to pressure, as were the quadratus lumborum, the deltoid, and many of the muscles of the arm and neck. There was considerable œdema of the eyelids and of the lower limbs. The urine was normal, and no disease of any abdominal or thoracic viscus could be detected. The patient complained of great prostration. Temperature, 103½° F.; pulse, 118; respirations, 24 per minute. Three living trichinæ were found in a small piece of the deltoid muscle by microscopical examination, and many of the muscular fibres were seen to have undergone granular and fatty degeneration.

"*Treatment.*—Bicarbonate of soda, ʒj, was administered every hour, until six doses had been given. Ol. ricini, fʒj, was then given, which produced very free catharsis. This treatment was repeated on the two following days. On April 17th the temperature was 101° in the forenoon and 103½° in the afternoon, and the muscular pain was so severe as to require the administration of morphia hypodermically. From April 18th

[1] Firing and electricity were employed, and, in addition to alimentation, constituted the treatment. The patient slowly improved, and in about two weeks was able to leave the hospital.

to April 21st the temperature ranged between 100° and 101¾°. On April 22d the temperature fell to 99¼°, and on the 25th to 98¾°. During this time the muscular pains became less severe, the œdema disappeared, and the appetite returned."

This case was in the service of my colleague, Prof. Janeway, and the patient was convalescent when he came under my observation. He is still confined to the bed, but the muscular pains have ceased, and he is able to bear considerable extension of the affected muscles. He has no fever, and the digestive organs are beginning to resume the exercise of their normal functions.

You will connect the vomiting, diarrhœa, and colic pains with the development of the parasites within the alimentary canal, and their passage through the gastro-intestinal mucous membrane. The fever and the general symptoms therewith associated are attributable to gastro-enteritis. The muscular pains are caused by the presence of the parasites in the affected muscles. The order of succession of these symptomatic events, and their occurrence shortly after pork, raw or imperfectly cooked, has been eaten, are diagnostic points; but the diagnosis is made demonstrative by obtaining a small piece of an affected muscle, and subjecting it to microscopical examination. In order to trace the disease demonstratively to its source, portions of the suspected article of diet should be microscopically examined. This was not practicable in the present instance.

I call your attention to the treatment of this case under the direction of Prof. Janeway. It consisted in the administration, for three consecutive days, of six drachms of the bicarbonate of soda, drachm doses being given hourly, followed by a cathartic of castor oil. This treatment had for its objects the destruction of parasites, and their expulsion from the alimentary canal. It is, of course, not proper to judge concerning the efficiency of treatment by the history of a single case, but it is noteworthy that, under this treatment, this case has progressed favourably, and the patient is now convalescent.[1]

The remainder of this lecture will be devoted to two cases of Pneumonic Fever or Acute Lobar Pneumonitis. In one of these cases bloodletting was employed for a particular object, followed by sponging of the body as an antipyretic measure. The other case was treated antipyretically by means of the wet sheet. It is proper to state that the treatment in these cases was under the direction of Dr. W. B. Anderton, House Physician of the division of this hospital with which I am connected; and that the treatment was directed by him without any instructions or suggestions from me. I shall read the histories, with all the details respecting the temperature at different hours of each day, during the duration of the fever, in order to present as fully as possible the therapeutical indications, and the immediate effects of the treatment. I hope you will not find these details tedious, when you consider the practical importance of the points which are involved.

The two patients are now before you. I will take up first the case treated by means of the wet sheet. The record is as follows:—

"Chas. L., æt. 32; Denmark; labourer; admitted May 16, 1881. The patient has no regular occupation; he has wandered about the streets, being exposed to all kinds of vicissitudes, and often remaining in wet clothes for hours. Four days before his admission he was suddenly seized with a

[1] The patient was discharged well on May 30th.

severe chill, followed, very soon, by fever, pain in the right side, and cough. The next day he was on the street, as usual, though feeling very weak. From that time until his admission he spent the days in the Battery Park, and the nights in a poor lodging house. On his admission the face had a dusky flush and an anxious expression. He complained of cough, pain in the right side, anorexia, and weakness. The axillary temperature was 104°; the pulse was 90, and strong; respirations were 26 per minute. Over the lower and middle lobes of the right lung were dulness on percussion, increased vocal fremitus, pure bronchial respiration, and bronchophony. No râles.

"The expectoration was rusty and adhesive. The heart, liver, and spleen yielded no abnormal physical signs. The urine was normal.

"The wet sheet was applied, and the patient left, uncovered, beneath it whenever the temperature reached 103° F. The sheet was not removed until the temperature of the mouth had been reduced to 102° F.

"Sulphate of quinia, in five grain doses, was administered every four hours, and five grains of carbonate of ammonia every three hours.

"*May 16th.* 5 P. M., temp. 104°; the wet sheet was applied. 7 P. M., temp. 101°; the wet sheet was removed. 9 P. M., temp. 102¼°. 11 P. M., temp. 102¼°.

"*17th.* 2 A. M., temp. 103¼°; the wet sheet was applied. 4 A. M., temp. 102°; the wet sheet was removed. 8 A. M., temp. 101¾°. 10 A. M., temp. 101½°; pulse 90; respiration 30. 12 noon, temp. 101½°. 2 P. M., temp. 102¼°. 4 P. M., temp. 103°; the wet sheet was applied. 5 P. M., temp. 103¼°; temp. taken by rectum, the sheet being still applied. 7 P. M., temp. 102¼°. 8 P. M., temp. 101¼°; the sheet was removed.

"*18th.* 12 P. M., temp. 101½°. 6 A. M., temp. 100¾°. 8 A. M., temp. 101¾°. 10 A. M., temp. 101°; pulse 72; respiration 30.

"Over the middle lobe the bronchial has given place to broncho-vesicular respiration and bronchophony to increased vocal fremitus. Subcrepitant râles are heard. The pneumonia, however, has invaded the upper lobe, and dulness, bronchial breathing, and bronchophony extend upward nearly to its apex. Pleuritic friction sounds are heard over the entire anterior surface of the lung. Bronchial respiration, bronchophony, and crepitant râles are now heard over the whole lower and over the lower portion of the upper lobe.

"*18th.* 12 M., temp. 102¼°. 2 P. M., temp. 102½°. 4 P. M., temp. 101°. 8 P. M., temp. 101¾°.

"*19th.* 12 P. M., temp. 102°. 4 A. M., temp. 101½°. 8 A. M., temp. 100¾°; pulse 72; respirations 24. 10 A. M., temp. 100½°.

"The respiration is, now, broncho-vesicular at the right apex anteriorly. Behind the signs are the same as on yesterday.

"12 M., temp. 101¾°. 6 P. M., temp. 101½°.

"*20th.* 8 A. M., temp. 101¼°. 8 A. M., temp. 100°.

"*21st.* A. M., temp. 98½°.

"*22d.* Temperature, A. M., 98½°; P. M., 98½°. The bronchial respiration and bronchophony, over the lower lobe and over the lower portion of the upper lobe, are less marked. Friction sounds and crepitant râles are still heard over both lobes, anteriorly.

"*24th.* Temperature normal. The respiratory murmur, over the affected lobes, is now broncho-vesicular in character, and bronchophony has been replaced by slightly increased vocal resonance. The patient sits up, and his appetite is excellent.

"29*th*. Resolution is complete, all the morbid physical signs due to consolidation having been replaced by the normal ones. Slight dulness still exists over the whole lower lobe, but this is referred to pleuritic thickening."[1]

The employment of the wet sheet as an antipyretic measure in the treatment of pneumonic fever is not a novelty in this hospital. In a lecture published in the number of *Gaillard's Medical Journal* for March, 1881, I reported three cases treated by this measure under the direction of Dr. Moeller, at that time House Physician of the division with which I am connected.[2] The treatment has been resorted to since the publication of that lecture in other hopital cases, and also in a few cases in private practice which have come under my observation. In all the instances thus far observed, the apparent effect of the treatment has been excellent. It remains to ascertain by clinical observation the circumstances, aside from the condition of hyperpyrexia, if there be any, which contra-indicate it. By the facts already observed I am justified in saying that in uncomplicated cases, a patient may remain in the wet sheet, with sprinkling of cold water at short intervals, without risk of harm, and with advantage, until the body-heat is reduced two, three, or more degrees, the period required for the reduction varying from a few to many hours, and that the measure may be safely repeated whenever the hyperpyrexia returns. In the case before us, it is fair to accord a certain amount of therapeutical influence to the quinia and the carbonate of ammonia which entered into the treatment.

Of the second of the two cases before you, the hospital record is as follows:—

"Sophia K., æt. 23; U. S.; domestic; admitted May 9, 1881. On May 5th the patient had a well-marked chill, with vomiting, headache, fever, and pain under the left nipple. She grew weak, lost her appetite, and felt unable to exert herself; but, nevertheless, kept at work until May 9th, when she entered the hospital.

"On admission the cheeks presented a circumscribed flush; the temperature was 102°; the pulse 120, and the respirations 40 per minute. The patient complained of excessive weakness and of pain in the left mammary region, with cough and rusty expectoration. Over the lower lobe of the left side there was increased vocal fremitus, with dulness, bronchial breathing, and bronchophony. No râles. The thoracic and abdominal viscera, with the exception of the lungs, were normal, as was also the urine.

"*Treatment.*—Whiskey, f℥ss every half hour; ammon. carbonat. grs. v every two hours; morph. sulphat. gr. ⅛, by mouth, every three hours; infus. digitalis, f℥ss, by mouth, every three hours.

"*May 9th.* 3.30 P. M. Œdema pulmonalis having been developed, Dr. Anderton performed venesection—removing twelve ounces of blood. This measure speedily relieved the symptoms due to the œdema. The latter became less marked, and the patient's general condition was considerably improved. 4.30 P. M., temp. 103½°; ordered whiskey, ℥ss every hour. 6 P. M., temp. 104°. 7 P. M., temp. 104°. 12 P. M., temp. 103½°.

"10*th*. 10 A. M., temp. 103¼°. The patient suffered from intense dyspnœa, which was effectually combated by the inhalation of oxygen gas.

[1] The patient was discharged on June 3 completely recovered.

[2] For an account of these cases *vide* Medical News and Abstract for May, 1881.

At 12 M., temp. 104°, 2 P. M., temp. 104¼°, and 4 P. M., temp. 104¼°; considerable dyspnœa; gave oxygen. 6 P. M., temp. 103¼°. 8 P. M., temp. 103°. 12 P. M., temp. 103⅛°.

"11*th*. 9 A. M., temp. 103°. 12 M., temp. 104¼°. 2 P. M., temp. 104°; great dyspnœa; gave oxygen. Ordered the patient sponged with tepid water, only one extremity being exposed at a time. 4 P. M., temp. 104⅜°. 5 P. M., temp. 103°. 7 P. M., temp. 104°. 8 P. M.. temp. 103°. 12 P. M., temp. 103°.

"12*th*. 5.30 A. M., temp. 103⅛°. 9 A. M., temp. 103¼°. 11 A. M., temp. 103¾°; sponge bath. 12 M., temp. 101¾°. 3 P. M., temp. 104°; sponge bath. 3.45 P. M., temp. 102¼°. 7 P. M., temp. 104°; sponge bath. 8 P. M., temp. 102°.

"13*th*. 1 A. M., temp. 102°. 7 A. M., temp. 101¼°. 9.45 A. M., temp. 101°. 2 P. M., temp. 102°. 5 P. M., temp. 102°; normal alvine evacuation. 7 P. M., temp. 102°. 9 P. M., temp. 101⅛°.

"14*th*. 8.45 A. M., temp. 99¾°. 11 A. M., temp 99°. The patient's condition is materially improved. On percussion diminished dulness is found; on auscultation broncho-vesicular respiration, increased vocal resonance and *râles redux;* on palpation the vocal fremitus but slightly increased. The whiskey was reduced to f℥ss every two hours. 6 P. M., temp. 99¾°; digitalis was discontinued.

"15*th*. 8 P. M., temp. 98¾°. 6 P. M., temp. 99¾°; stopped the carbonate of ammonia; ordered whiskey f℥ss t. i. d.

"16*th*. A. M., temp. 98¾°. P. M., 99°. Physical examination now shows only slight dulness. The broncho-vesicular breathing has been replaced by natural vesicular respiration, and the vocal resonance is normal.

"18*th*. A. M., temp. 98¼°. P. M. 98½°. Ordered tr. ferri chloridi, gtt. xx t. i. d.

"19*th*. A. M., temp. 98¼°. The patient is now fully convalescent."[1]

An important event in this case was the occurrence of pulmonary œdema. Occurring in connection with pneumonia, and limited to the lobes not solidified by the pneumonic exudation, it is known as "collateral œdema." The diagnostic evidence of its occurrence is the more or less sudden development of rapid breathing and of cough with serous or serosanguinolent expectoration, these symptoms associated with subcrepitant râles over the lobes not affected by the pneumonia. The explanation implied in the term collateral is that the blood in consequence of the obstruction to the circulation in the solidified lobe or lobes, is determined in excess to the lobes not solidified. Were this the sole explanation, however, the so-called collateral œdema in cases of pneumonia and of pleurisy with effusion should be frequent, whereas it is of rare occurrence. Nor is it easy to understand why the œdema should occur suddenly, and when the obstruction has existed for some time as in the case under consideration. A better explanation is that the œdema is due to the same causes which induce it when pneumonia does not exist. The œdema implies pulmonary congestion, and the latter, in the second stage of pneumonia, cannot take place in a solidified lobe for an obvious mechanical reason; hence the congestion and œdema are limited to the lobes which are not solidified. As to the causes of pulmonary œdema I cannot go into their consideration now; but I would remark that my colleague, Dr. Wm. H. Welch, has demonstrated, experimentally, that the proximate cause is

[1] Recovery took place without any untoward symptoms.

weakness of the left ventricle of the heart, associated with either increased or undiminished power of the right ventricle.

Pulmonary œdema existing in a degree to occasion notable embarrassment of respiration is treated most efficiently by bloodletting. Dr. Anderton very judiciously adopted this measure in the case before us. Notable relief followed it, and the dyspnœa which remained was relieved by the inhalation of oxygen gas.

In this case the febrile temperature indicated efficient antipyretic treatment. The wet sheet was not employed lest it might do harm in view of pulmonary œdema having occurred. The latter was perhaps not a contra-indication, but if we must err in medical practice it is generally best to err on the side of caution. Sponging of parts of the body was, however, resorted to, and with the effect of reducing the temperature. Let me here remark that sponging the surface of the body continuously for a long period, will often accomplish all that is to be obtained by the wet sheet or the cold bath. This method of antipyretic treatment has the recommendation of not appearing to be in such violent antagonism to popular traditional notions as the sheet or the bath.

CASE OF TREPHINING FOR ANOMALOUS CONVULSIVE ATTACKS, SUPERVENING SEVERAL MONTHS AFTER INJURY TO THE HEAD.

A Clinical Lecture.

By J. W. HULKE, F.R.C.S., F.R.S.,
Surgeon to, and Lecturer on Surgery at, the Middlesex Hospital.

GENTLEMEN: The subject of my last clinical lecture[1] was a little child who had undergone secondary trephining for abscess following a punctured wound of the vault of the skull, with lodgment of splinters of bone and hair in the brain. The case to which I invite your attention to-day is that of a young man in Bentinck ward who has recently been trephined for fits following an injury in the right temple.

The following is the record abridged from my dresser's (Mr. Thane) notes:—

A ticket-clerk, aged twenty-one years, who as a youth was considered delicate and to have phthisical tendencies, was admitted into the hospital on January 23, 1879.

Six months previously, at 5 A. M., he slipped off a railway-platform, which was greasy with wet, and falling upon the line, about four feet lower than the platform, struck his right temple, it was supposed against the parapet of a dwarf wall. He was stunned by the blow, which was severe, for although the distance through which he fell was not great, he was running quickly at the moment which increased the impetus. How long he continued unconscious is not known—probably not longer than a few minutes. On recovering consciousness he found himself upon the ground. He managed to rise, get upon the platform, and reach the next station, about three-quarters of a mile distant, where he reported his accident to the station-master. A bruise, and a bump of about the size of the last joint of the thumb, were seen on his right temple by his father, a guard, and by others. His head ached greatly, and it felt very confused, but he managed to perform his duty until mid-day, by which time the headache and confusion of mind

[1] See page 330, *ante*.

had become so great that he was compelled to leave work, and he then went to a friend's lodgings near the station, where he sat down in a chair. About 4 P. M. his friend thought he had fallen asleep; he had, however, become deeply unconscious, and could not be roused. He was therefore put to bed, where he remained unconscious of what was happening during twenty-four hours, when he awoke, and was startled to find himself undressed, in his friend's bed, with two doctors examining him.

During about one month he continued deeply soporose, sleeping heavily during several hours, then waking and taking food. He did not, however, feed himself, appearing to be unable to hold the cup or to manage a spoon. He had complete control over his bladder, but it was necessary to place the vessel, for he seemed unable to arrange it or hold it himself. He had also control of the bowels, and he always intimated his wants to those in attendance upon him. Throughout this month he did not leave his bed; he seemed to have become too weak to stand.

In the condition just described he was next taken to his parent's home in a seaport, seventy miles distant. He did not appear to be much exhausted by the journey. The quiet, the surroundings of home, and the fresh sea-breezes appeared to benefit him, and he slowly and gradually recovered, becoming able, at the end of a few weeks, to creep about in the garden. At the end of two months (three months after the accident) he had improved so much that he made an attempt to resume work, but this aggravated the headache, which had never left him, and he could not bear even slight mental strain without becoming confused; so that, after a fortnight, he was obliged to return into the country to his parent's with whom he remained until his admission into this hospital. During all this time he was never free from headache, and latterly he occasionally had what were called slight seizures, twitchings, and very transient unconsciousness.

Five days before being brought to the hospital he was violently convulsed—in twenty-four hours he had fourteen very severe fits; the convulsions were so strong that three men could not restrain him. During the fits and for some time after he seemed to be quite unconscious. In the course of the next day and night he had ten similar fits, and on the third night he was convulsed with little intermission from 10 P. M. till 2 P. M. on the fourth day. He did not bite his tongue nor foam.

When I saw him on the fifth day after his journey of 100 miles, he looked like a convalescent from a severe illness. His face was pale, his pulse weak (100 per minute). The surface of his body was mottled, and it felt cold to the hand. The thermometer in the axilla, however, marked 99° Fahr.

His mind appeared to be unclouded; his memory was good; he gave a coherent account of the accident and his subsequent illness; and when questioned, his answers were always pertinent. His statements (corroborated by his father) were remarkably clear and consistent.

He complained of constant headache and dizziness, of a tightness as if a cord were tied round his forehead, and of a hammering in the back of the head. His visual acuteness was unimpaired, but he said that on reading his sight soon failed. No indications of inflammatory or congestive disorder of optic nerves was discernible. Just behind the right temporal ridge, about one inch above its origin, in the spot where the bump was noticed on the day the accident occurred, was a very limited area, pressure on which caused, he said, a darting sensation through his head. This spot was marked with an ink-dot, and diverting his attention by questions referring to other matters, the smooth end of a pencil was repeatedly made to cross it in different directions, with the result that he always winced and exclaimed, "It darts through my head." No scar was discernible here; the

soft coverings seemed to be quite natural, and no unevenness of the underlying bone could be felt.

At 7.20 P. M. he made a curious noise, so like a snarl or bark that the patients in the neighbouring beds thought a dog had got into the ward. His hands were then noticed to be clenched, and he became violently convulsed. The House-Surgeon, who saw him within a very few minutes of this attack, found him then quiet and apparently quite insensible; his eyes were strongly rolled upwards—the left appeared more elevated than the right. After about five minutes, the masseter muscles were observed to stand in tense relief, and the upper lip was raised, showing the teeth and gums. The teeth were tightly clenched. Then his fingers became flexed, and the arms rigidly stiff through violent contraction of their muscles. The muscles in the nape of the neck were soft, and not contracted. Seven such fits occurred at intervals of about five minutes, ushered in by the strange barking noise. There was then a calm interval of half an hour, followed by another fit, after which consciousness returned. He then asked for a chamber-pot, and micturated. At 11 P. M. he had two more fits. He passed the rest of the night quietly, appearing to sleep.

January 24. At 9 A. M., temperature 98.4°, pulse 84. Calm and sensible. Headache continued. At 3 P. M., two fits.

25*th*. 9 A. M., temperature 97.4°; pulse 86. Slept from eleven o'clock last night till seven this morning. Headache and dizziness unchanged. 9 P. M., temperature 98.4°. At 10 P. M., whilst apparently sleeping, began to mutter, then made a barking noise, and was convulsed six times in half an hour—after which he became conscious. In these fits there was extreme opisthotonus.

26*th*. 9 A. M., temperature 98°, pulse 78. More headache. At 7 P. M. a convulsion lasting five minutes; after which he continued unconscious during half an hour.

27*th*. In the course of the morning, five fits; and in the evening, four fits. Temperature 98.4°; pulse 84.

28*th*. During forenoon, three fits. Temperature 98.6°; pulse 96. Up to this time he had been taking large doses of potassium bromide. At mid-day he was placed under the influence of chloroform, and trephined at the spot in the right temple, where, as already mentioned, pressure always caused a darting pain through the head. In the soft coverings, and in the disk of bone removed, no trace of injury or structural change was discernible. The dura mater also appeared normal. An aspirator-needle was therefore pushed through this to the depth of rather more than an inch, upon which, as nothing escaped through it, the needle was withdrawn. For a few moments, cerebro-spinal fluid spurted in a slender stream through the prick in the dura mater to the distance of nearly a foot. The middle of the scalp-wound was purposely left open. Throughout the operation, and subsequently, strict antiseptic measures were observed.

During the next forty-eight hours no fits occurred. The temperature ranged between 98.4° and 99°, and the pulse averaged 80. He was cheerful but calm, and took fluid nourishment freely. His headache was, he said, much less. Movements of the lower jaw caused much pain, obviously referable to the division of the temporal muscle in the operation.

In the afternoon of the 30th he was allowed to see his father, which appeared to excite him. Later, at 5.30 o'clock, he seemed to become unconscious, and at 6.15 he was slightly convulsed.

February 1. At 1.15 A. M., a slight fit; at 11.45, a slight fit, preceded by unconsciousness of about twenty minutes' duration; and at 9.30 P. M., unconsciousness, which lasted twenty-five minutes, when he came-to without convulsion. Temperature ranged from 98° to 99°.

2d. One slight convulsion. Temperature 98.2°; pulse 84. Potassic iodide gr. x. t. d. now ordered.

3d. At 12.15 P. M., a strong fit.

4th. Had a calm day, followed at 8.40 P. M. by several violent fits.

5th. Between 7 and 9 A. M., six fits.

7th. Temperature 98°; pulse 56, in afternoon intermittent. The dose of iodide of potassium was diminished by half—to gr. v. t. d. 8.30 P. M.: Unconscious during five minutes, after which a severe fit of convulsions, lasting half an hour; followed by four more fits between 3.30 and 4 A. M.

On the 12th he began to take valerianate of zinc in doses of gr. iss, t d. On the 15th this was increased to gr. ij, 4ta quaque hora; then to gr. iij, gr. iv., and finally (on the 24th) to gr. vj, 4ta q. h.

After this date he had no fits until March 6, when he was unconscious during several hours, and was violently convulsed several times.

7th. Allowed to leave his bed and sit in an easy chair. The valerianate of zinc pills were now taken only four times in twenty-four hours. From this time he appeared to improve.

On the 15th he declared himself quite free from headache, and he had not had any fit for eight days.

On the 16th he returned home. At this time he could walk a little; had a good appetite, and was free from headache.

The early symptoms in this most remarkable case are those which are generally thought to indicate severe concussion of the brain. When death has occurred soon after an injury to the head, followed by such symptoms, not infrequently bruisings, slight lacerations, and small hemorrhages in the cortex of the brain have been demonstrated. The severity of the early symptoms, the tardy and imperfect recovery, warranted the belief that such surface-damage of brain had occurred here. The unconsciousness which supervened later on the day of the accident raised the suspicion that a coarse hemorrhage had happened; but the interval—twelve hours—between the accident and this unconsciousness was exceptionally great for it to have been due to pressure through hemorrhage, and the subsequent progress was also inconsistent with such a supposition.

What were the fits which came on six months after the time of the injury?

In those which occurred on the day he was taken into the hospital, the House-Surgeon noticed very marked *trismus;* the masseters became like rigid bars, and the lower jaw was tightly clenched.

In subsequent fits extreme *opisthotonus* occurred. The occiput and rump nearly touched.

Trismus and *opisthotonus* are, as you know, characteristic features in tetanus. Our patient, however, certainly had not tetanus, for during the cramp of the masseters the muscles of the nape were soft and uncontracted, those of the hands and forearms were as violently convulsed as those of the trunk, and in the intervals between these terrible fits none of the muscles were unnaturally rigid; whilst in tetanus, rigidity of the muscles of the nape is early associated with trismus, and it precedes the implication of the muscles of the trunk, the muscles of the hands and forearms usually escape, and between the convulsive paroxysms all the implicated muscles continue stiff through inordinate tonic contraction. It was evident, then, that these convulsive fits were not tetanic: were they epileptic?

The earliest seizures noticed at home, a few days before the first convulsions, were not unlike those of the least severe form of epilepsy—transient unconsciousness ("he seemed to lose himself for a moment") and slight twitchings. That epilepsy sometimes has a traumatic origin cannot be doubted. Its sequence upon

injuries of the head affecting the brain has been observed too frequently to allow this to be regarded as a casual coincidence. We have had in the surgical wards within the last two years two instances of this. In the present case the increase of headache in the right temple, which often, he said, shortly preceded a fit, and the darting pain through the head on touching the site of the bruise at this part, favoured the supposition of a causal relation between the injury and the fits; and this supposition was strengthened by the continuance of headache and dizziness during the intermediate time between the injury and the occurrence of the fits—symptoms suggestive of the existence of some chronic irritative process at the injured spot.

Against the idea that the fits were epileptic was the manner in which they often began: the patient, who a few moments previously had been talking rationally and coherently, appeared to lose the thread of the sentence; he muttered disconnected words, repeating the same word again and again—mostly a word occurring in the last coherent sentence he had himself spoken, or in the last sentence addressed to him. He did not become unconscious instantly, but gradually, and a period varying from a few minutes to half an hour often preceded the convulsions. Occasionally the first convulsions had the aspect of purposive movement. He, on two occasions when I was myself present and saw it, distinctly made a snap at a dresser who happened to be at his bedside, and tried to seize him with his teeth. His tongue was never bitten.

As, however, the fits seemed to differ least from epilepsy, bromide of potassium, so useful in this disorder, was tried in large and frequent doses. It had not any controlling influence; the fits continued with great violence. It was now that recourse was had to trephining. As you have already heard, nothing abnormal was discovered. The high intra-cranial pressure, sufficient to project a spurt of cerebro-spinal fluid to the distance of nearly one foot, is worth notice. The fluid continued to leak during several hours afterwards in quantity enough to wet the boric charpie with which the wound was covered, and the pressure will have been for some time lowered. Had this lessened tension any causal connection with the absence of fits during the next sixty hours or so? On their return, iodide of potassium was next tried in doses of ten grains, diminished one-half when, after a few days, the pulse began to be very weak and to intermit. It was, however, soon apparent that this drug also was without influence over the malady. The similarity of the fits in respect of the occasional purposive character of the initial convulsions, and also in respect of the opisthotonus which sometimes occurs in violent hysterical convulsions, next led to a trial of valerianate of zinc, which was taken at first in doses of one grain and a half, and finally in six-grain doses at short intervals. Under this treatment the fits subsided, which favours the idea of their hysterical nature. In some recently published cases of violent hysterical convulsions in young women, it was related that pressure in the inguinal regions, directed so that it might be supposed to reach the ovaries, quickly arrested the convulsions. As an experiment, compression of the homologous organs, the testes, was tried here during some fits, but without any effect upon them.

Upon the whole the conclusion which has the largest support in the facts of this case is that the fits were hysterical, induced by the shock of the accident in a person whose nervous system was not particularly stable, and that they were not immediately dependent upon a local irritative process set up by the blow on the temple; trephining, therefore, whilst it did not appear to have done any harm, was useless. In the case which I very recently brought before you, you will remember that the symptoms of cerebral disorder were one-sided: this gave them a very different signification to that of the convulsions in the present case, which were not restricted to one side, but implicated both sides equally.

Note.—After the patient's return home, he fell into what was called a "galloping consumption," and died on July 14 following. An examination of the head showed that the trephine-hole in the skull, which had measured eleven millimetres across, had been completely closed by new bone—a result probably referable to the small size of the trephine and the preservation of the pericranium, which was in a normal condition at the time of operation. No trace of the puncture with the aspirating-needle was discernible in the dura mater or brain.

The brain weighed forty-eight ounces; it was well formed and symmetrical. The pia mater, especially that covering the posterior lobes, was congested. No trace of injury could be detected by most careful examination—no scar or depression or mark of former contusion or laceration; the surface of the brain appeared quite normal. The white and gray matter of the hemispheres were firm; the puncta vasculosa rather more conspicuous than usual. Each hemisphere was carefully sliced for traces of previous injury; none whatever were found. The only pathological conditions were four small yellowish nodules. One of these, about the size of a large pin's head, was in the gray matter of the anterior part of the corpus striatum, close to its upper surface; a second, slightly larger, was in the gray matter of one of the convolutions of the left frontal lobe; the two others were one in each cerebellar hemisphere—also in the gray matter, that in the right side being the larger, and about the size of a horse-bean.—*Med. Times and Gazette*, July 23, 1881.

Hospital Notes.

BELLEVUE HOSPITAL, NEW YORK.

(Service of Dr. AUSTIN FLINT, Sr.)

(Specially reported for the MEDICAL NEWS AND ABSTRACT.)

Transient Mellituria. Cardiac Disease.

Annie M., æt. 66, Ireland, domestic; admitted Dec. 6, 1880. The patient had malarial fever fifteen years ago. After that time she enjoyed good health until two years ago, when she had acute articular rheumatism involving the knees, ankles, and feet. The arthritic disease, having received no treatment, became chronic, and obliged the patient to seek admission to the hospital. On admission (Dec. 6, 1880), the patient had no pulmonary disease. The heart was hypertrophied, the apex being situated in the sixth intercostal space on the *linea mammillaris*, and the impulse being abnormally strong. A loud, musical, systolic murmur was heard at the apex, and was transmitted to the left, around the chest, being plainly perceptible behind, near the angle of the scapula. Another murmur was heard at the base, over the aortic valves, and was transmitted into the carotids. The patient had a good but not an unusually large appetite. She was not emaciated. She did not suffer from thirst. Her vision was not impaired. Her temperature was normal. She had no cutaneous eruptions or abscesses. Her tongue was moist, and her teeth perfectly sound. She micturated at natural intervals, and had no strangury or *ardor urinæ*. The vulva was not excoriated or tender. Her urine was pale, clear, acid in reaction, and its specific gravity was 1029. It contained an abundance of sugar, but neither albumen, casts, nor other abnormal ingredients. No medication was resorted to.

December 10. The urine has been carefully examined every day since the patient's admission and found to contain no sugar until to-day, when it was discovered to contain eight grains to the ounce. Some urine was withdrawn from

the bladder by a catheter to prevent the possibility of deception, and was found to contain the same proportional quantity of sugar.

11*th*. The patient has passed only twenty-one ounces of urine during the last twenty-four hours. Its specific gravity is 1033, and it contains ten grains of sugar to the ounce.

12*th*. Amount of urine, twenty-four ounces; sugar in abundance.

13*th*. Amount of urine, twenty-two ounces; large amount of sugar.

21*st*. The amount of urine has averaged twenty-five ounces since the last note, and has contained about ten grains of sugar to the ounce. The patient's general condition is excellent, and all her bodily functions are naturally performed.

25*th*. No change in the urinary condition.

28*th*. To-day the sugar suddenly disappeared from the urine, and the amount passed was increased to four ounces.

January 19, 1881. Average daily amount of urine is now forty-five ounces, and it contains no sugar.

30*th*. A careful daily urinary analysis has failed to detect any sugar since last note. The average daily amount is now sixty ounces, and its specific gravity 1020.

February 18. The patient has no symptoms or signs of diabetes. Her urine is normal. She experiences no inconvenience from her cardiac disease, and has only slight stiffness in her rheumatic joints. She was to-day discharged.

Eliz. L., æt. 35, U. S., domestic; admitted Dec. 16, 1880. Six years ago the patient had her first attack of acute articular rheumatism which involved almost all her joints and was attended by præcordial pain and by dyspnœa. She has had several similar attacks since that time. Three years since she first noticed œdema of her lower extremities, which has persisted up to the present time. She has had abnormal frequency of micturition, but no diarrhœa, emesis, or headache. Has had a slight cough and scanty muco-sanguinolent expectoration. She has lost flesh, but has had no night-sweats. On admission she complained of dyspnœa, præcordial pain, and œdema of the legs and feet. The heart is hypertrophied, the apex-beat being situated in the fifth intercostal space, an inch to the left of the mammary line, and the impulse being unusually strong. A thrill is communicated to the palpating fingers. An organic mitral regurgitant and an aortic direct murmur are heard. A prediastolic murmur exists at the base. There is slight pleuritic effusion on the right side. The lower extremities are very œdematous. The temperature, pulse, and respiration are normal. There are neither excessive appetite, great thirst, nor other symptoms of diabetes. The urine, which is clear, alkaline, and has a sp. gr. of 1009, contains a trace of albumen and a considerable quantity of sugar. The quantity of urine passed in twenty-four hours is thirty-five ounces.

Treatment.—Infusion of digitalis, f℥ss, every three hours, and a liberal diet of milk and eggs.

December 16. The patient has improved notably since her admission. The œdema and dyspnœa have diminished and the pleuritic effusion decreased. The average daily quantity of urine has been seventy ounces, and it has contained about six grains of sugar to the ounce.

17*th*. The sugar has disappeared. The digitalis was continued.

27*th*. The urine has been normal in quantity and chemical character since last note, and the patient is rapidly gaining strength.

January 10. The patient was discharged in good health, the pleuritic effusion, œdema, melliturie, and albuminuria having disappeared.

MONTHLY ABSTRACT.

Anatomy and Physiology.

Microscopic Structure of the Cortex Cerebri.

Professor Betz (*Centralblatt für die Med. Wiss.*, 1881, Nos. 11, 12, and 13) has endeavoured, by his histological researches, to verify the statements of Hitzig and Ferrier respecting the localization of functions in the cortex cerebri. In 1874 he pointed out that the "motor zone" contained large cells, to which the name of giant-cells was given, though they have nothing to do with the giant-cells which play so large a part in the modern descriptions of new growths. He says, the cortex cerebri, as is well known, is composed of five layers, as follows: 1, a layer of neuroglia, containing small granular nuclei; 2, in addition to the preceding, there are pyramidal cells of medium size, with the apices directed towards the periphery, and their bases towards the central parts; 3, very large pyramidal cells, which are, however, fewer and scattered; 4, small round or elliptical cells, constituting the "nuclear layer;" 5, special fusiform cells.

This is the typical arrangement, but the various regions show differences. Thus, Meynert has shown that, in the neighbourhood of the calcarine fissure, the third layer is absent, and the structure in this region consists of two nuclear layers separated by a layer of nerve-fibres, on which lie by pairs large pyramidal cells. The hippocampus also is principally composed of the elements of the third layer. The claustrum consists of the elements of the fifth layer; the ascending frontal, and the paracentral lobe, contain "giant-cells" grouped in nests.

He has examined 5000 preparations from brains of all ages, and has come to recognize, in addition to the above, certain other regional peculiarities.

The *ascending frontal convolution* in its upper two-thirds, presents the following characters. At first, just above the fifth layer, there are large cells, single or united by pairs, and at great intervals one from another; higher up, these cells are grouped in threes and fours, and the intervals are less. Higher still, the groups are formed by a large number of cells, not less than four, often six or seven. In the third layer they present an uninterrupted series. In the second, they are scattered as in the fourth. Near the paracentral lobe, this series is again interrupted so as to form groups or nests. Nearer the lobe the cells become larger, until they pass into the condition of the true giant-cells of that region. These latter are never found in the ascending parietal.

The *convolution of the corpus callosum* is composed at its origin, beneath the anterior part of the lamina terminalis, almost exclusively of two layers, the superior and the fifth; while the cells of the latter, instead of being parallel to the base of the convolution, are perpendicular, like the cells of the third layer elsewhere, and they are two or three times larger than the ordinary fusiform cells of the third layer. In the middle of this convolution, the "nuclear layer" (fourth), and the layer of pyramidal cells, reappear. In the posterior third, three new layers occur. The first, lowest, is composed of longitudinal fibres, forming an arch over the upper surface of the corpus callosum. The second layer, gray, is formed of small round cells; the third, equally gray, contains pyramidal cells, and also large fusiform cells. These three layers become more and more important towards the extremity of this convolution, but never involve more than

its inferior and internal portions. Where the convolution of the corpus callosum passes into the hippocampus, the layer of large cells suddenly increases, and goes to form the internal cellular layer of the hippocampus. The nuclear layer, above described, becomes the well-known nuclear layer of the hippocampus; and the layer of white fibres adjacent to the corpus callosum passes to form the reticular white matter of the hippocampus.

The *extremity of the hippocampus*, and the terminal part of the temporal lobe, present the peculiarity that the pyramidal cells of the third layer are found immediately beneath the first, and are arranged in groups like balls of thread, whence they have been named by Betz *cortical glomeruli*.

The *third frontal convolution* is separable into three parts, the most posterior extending from the ascending frontal convolution to the perpendicular branch of the fissure of Sylvius; the middle portion extends from this limit to the beginning of the orbital portion of the convolution; and the third, situated on the under surface of the brain, extends from the extremity of the convolution to the island of Reil. The first portion contains in the third layer pyramidal cells of larger size than are found elsewhere in the frontal lobe; and in brains of persons of advanced age, there may be giant cells of small size, which pass into the extremity of the ascending frontal. The second portion contains, in the second and third layers, long, slender, pyramidal cells grouped together, and with their processes directed obliquely. The third portion contains chiefly cells on the type of the fifth layer, and of the size of those of the claustrum, arranged, generally, perpendicularly to the transverse section of the cortex; sometimes there are some cells of the third layer, but they are very small.

The *island of Reil* contains numerous small cells, like those of the fifth layer.

The *lingual lobe* possesses eight layers from without inwards: 1, the layer of neuroglia; 2, very small pyramidal cells; 3, nuclei; 4, horizontal fibres; 5, nuclei; 6, horizontal fibres; 7, triangular pyramidal cells; 8, fusiform cells.

The *fusiform lobule* has an analogous structure; but, as it approaches the occipital lobe, the seventh layer disappears, and at the end of the descending gyrus all the layers unite to form a homogeneous mass of nucleated cells, and a little row of fusiform cells.

The external portion of the *occipital lobe* has the second and third layers of pyramidal cells of the ordinary type, and here and there there are cells of large size.

The *angular gyrus* has an analogous structure, but the cells of the third layer are much larger than in the occipital lobe.

The *ascending parietal convolution*, and *superior parietal* and *inferior parietal lobules*, have the ordinary typical structure.

The three *temporal convolutions* are distinguished by the thickness of the fifth layer, and by the presence of small cells in the third.

The *parieto-temporal* and *transverse temporal* convolutions are of the ordinary type.

The *quadrate lobe* has near its upper border, in the third layer and above the fifth, two rows of pyramidal cells.

The *frontal convolutions*, excepting the lowest, already described, have a very thick third layer of large pyramidal cells, which almost obliterates the fourth layer.

The *straight gyrus* is very like the convolution of the corpus callosum.

In the *female*, the third layers in the frontal and parietal lobes are thinner, and the pyramidal cells fewer; while in the occipital lobes, the same layer presents larger and more numerous cells.

In the *embryo*, at seven months, the cortex is composed of only two layers, the first and fourth, and pyramidal cells may be seen only in the hippocampus.

In the *new-born child* the cortex is much the same, but the hippocampus has all its elements as visible as in the adult, and in the paracentral lobe there are some giant-cells, which may be distinguished by their pyramidal form and three prolongations. At the age of *six weeks*, the pyramidal cells of the third layer may be observed in several convolutions.

In *children of eleven to twelve years* the giant-cells have still few prolongations, the apical prolongation is still short and pale, and no basal prolongation has been observed.

In the case of an *idiot* (Mottè), the frontal lobe was composed of irregular, slender pyramidal cells, in which it was impossible to distinguish the five layers. The giant-cells of the ascending parietal and paracentral regions were narrow, oblique, and furnished with few prolongations, the basal prolongation being absent. The parietal and occipital lobes had the nuclear layer well developed, while the pyramidal layer was small, thin, and contained chiefly the small pyramidal cells of the second layer. The *hippocampus* had its white substance very well developed; its characteristic cellular layer was small, as was also the nuclear layer.

With respect to the origin of the olfactory nerve, the olfactory tubercle contains a first layer of small pyramidal cells, few in number; a thick layer of nuclei, and large cells in the fifth layer, like those in the convolution of the corpus callosum. There is, in the inferior portion of the tubercle, a bundle of white fibres, coming from the corpus callosum; and the same region contains a gray layer, consisting of oval ganglionic cells, of large size, and furnished with processes, recalling the cells of the cornua of the spinal cord. In the brain of Mottè, this gray layer was much better developed than usual. This gray layer may be called the central ganglion of the olfactory tubercle.

These facts afford an anatomical confirmation to the researches of Ferrier. Convolutions are organs separated by sulci, or fissures, in which lie the blood-vessels supplying them. The larger the convolutions, the greater is the development of the particular organ; and the more numerous of the convolutions, the greater is the specialization of function.—*Lond. Med. Record*, July 15, 1881.

—

Anatomical Structure of the Mammary Gland.

In the *Verhandl. der Phys. Med. Gesellsch. in Würzburg* (Band xiv., Heft 3 and 4) Prof. KÖLLIKER gives a detailed descriptions of the minute anatomy of the male and female mamma at various ages. In the new-born infant, sex makes very little difference in the structure. At this period there are no terminal gland-vesicles, the ducts are lined with a single layer of cylinder epithelium or with a few layers of pavement cells, and end in club-like extremities. The ducts he finds in all cases irregularly dilated, the dilatations being filled with shed epithelial cells and a white granular material—forming the so-called "witch-milk," which he regards as normal. During the first year, the most noticeable point is the great dilatation of the ducts, giving the organ a cavernous appearance. The ducts are lined, according to the amount of dilatation, either with flattened epithelium or with several layers of round cells; and those which reach into the depth of the organ have now several club-like terminations. Strings of cells, afterwards developing into fat-cells, are also seen in the deeper parts of the gland. The above-mentioned dilatations gradually diminish during the latter half of the first year, till the lumen is normal, but in some cases swelling of the gland goes on, and a true mastitis results, from which, in all probability, follow those cases of imperfect development of the breast in otherwise well-developed women. From the age of one to ten little change takes place beyond the de-

velopment of fat around the organ and the increase of the septa of connective tissue.

From ten to twenty, the male mamma changes but little, although the terminal gland-vesicles may develop here and there on one or both sides. From twenty to thirty, the male mamma reaches its highest development. The ducts divide dichotomously at their extremities, and send off cellular processes which develop into vesicles. The cutaneous papillæ, the smooth muscular fibre, and the sudoriparous glands, are also much developed. From thirty to fifty, regressive changes occur, gradual disappearance of the terminal vesicles from fatty degeneration of the epithelium with contraction of their lumen and a matting of the connective tissue. The ducts also become tortuous and varicose, and, in later life, there is a great enlargement of the sebaceous glands.

In the virgin mamma, there is no division into lobes. The great part of the gland lies underneath the areola and towards the lower segment of the organ. The cutaneous papillæ are not much developed, and the interstitial tissue is almost tendinous in structure. The gland-vesicles are few in number, even at the age of twenty. They are formed by cellular offshoots from the ducts, at first solid, but gradually acquiring a lumen. In pregnancy, this process goes on rapidly and in large extent. Circular and longitudinal smooth muscular fibres are present in considerable quantity; both classes of fibres being tolerably uniform on the nipple, while the circular fibres seem to preponderate in the areola. During menstruation, although the organ sometimes becomes harder and more sensitive, the author discovered no change. Probably the symptoms are caused by a temporary hyperæmia, producing more rapid growth. During pregnancy and lactation, the papillæ on the nipple are broad but not high, those on the areola are long and pointed. The rete Malpighii contains a thick layer of yellowish-brown pigment. From eighteen to twenty-two ducts converge to the depression of the nipple to open between the cutaneous papillæ, each of these ducts being made up of from four to fourteen branches. The connective tissue of the gland is loose and relatively less in quantity. The terminal vesicles are now well developed, forming a well-marked racemose gland. They are best developed in the deeper parts of the gland, the superficial part consisting mainly of excretory ducts and connective tissue. Between the papillæ of the areolar space are found the prominences of Montgomery's glands, especially developed sebaceous glands, about a dozen in number. Regressive changes follow pregnancy and lactation, general relaxation of the breast, the nipple and areola retaining their size, although the pigmentation slightly lessens in degree. The vesicles also lessen in size. The lobules become separated by more connective tissue. Later in life, the whole glandular tissue disappears except the excretory ducts; the fat also atrophies, and we have the pendent breasts of age.—*Lond. Med. Record*, July 15, 1881.

Materia Medica and Therapeutics.

Waldivin.

A short time since, M. TANRET separated a crystalline neutral principle from the fruit of *Simaruba Waldivia* (which should not be confounded with that of *S. Cedron*). Some physiological experiments carried out by M. DUJARDIN-BEAUMETZ (*Comptes Rendus*, tome xcii.) show that this principle, waldivin, is a powerful poison, but slow in its action, death in the case of dogs not occurring until from five to ten hours after injection, even when the dose is many times

that necessary to produce death. In the human subject and in dogs it provokes vomiting when administered by the stomach, but rabbits fall into a profound stupor, which continues until death. In cases of snake-bite and hydrophobia it has failed to prevent a fatal termination, though, when administered to mad dogs in doses of one milligramme daily, it is said to cause an entire suppression of the exacerbations, the animals remaining insensible and dying without convulsions. Waldivin does not appear to exercise any influence in cases of intermittent fever. On the other hand, cedrin, the corresponding principle of *S. Cedron*, is less toxic, but possesses decided febrifuge properties, though the action is slower and less sure than that of quinine. Like waldivin, cedrin exercises no influence in cases of snake-bite; so that, if there be any foundation in the popular reputation in South America of the seeds of *Simaruba Cedron* as a specific against the bites of venomous serpents, it is not due to this principle. Neither substance produces toxic symptoms in frogs, even in large doses.—*London Med. Record*, June 15, 1881.

—

Xanthoxylum Naranjillo as a substitute for Jaborandi.

A rutaceous plant, growing wild in the Argentine Republic, where it is called "naranjillo," and which has recently been described as a new species by Griesbach, under the name of Xanthoxylum Naranjillo, has been examined by D. PARODI (*Revista Farmaceutica*, vol. xviii., and *Pharm. Jour.*). His attention was directed to it through its resemblance to pilocarpus jaborandi in its therapeutic properties, which are those of a sialogogue, sudorific, diuretic, and stimulant. He reports that he has separated a substance forming salts with acids, having a decided alkaline reaction, and giving all the reactions characteristic of an alkaloid, which he has named "xanthoxylina." The plant also yielded a hydrocarbon, "xanthoxylene" ($C_{10}H_{16}$), analogous to pilocarpin, a crystalline stearoptene, xanthoxylin, and finally an aromatic essential oil, having an odour between balm and lemon. From the great similarity of this plant to jaborandi, it appears worthy of further experiment in a therapeutic direction.—*London Med. Record*, June 15, 1881.

—

Oxidized Oil of Turpentine as a New Antiseptic.

Mr. C. T. KINGZETT, in the *Lancet*, June, 1881, p. 971, brings forward the oil of turpentine, through which air has been passed for a prolonged period, as a valuable antiseptic agent, being at the same time much cheaper than oil of eucalyptus and more intensely antiseptic than this drug, besides being free from all the objections that attend the use of this agent. Mr. Lister is making trial of the oxidized oil of turpentine, the result of which the profession will await with interest.—*Lond. Med. Record*, July 15, 1881.

—

Naphtha Oil in Affections of the Skin.

Prof. KAPOSI read a paper at the Vienna Medical Society (*Wien. Med. Zeit.*, May 10), in which he stated that he had employed this substance (the B naphtha oil, largely used by colour-makers) as an advantageous substitute for tar, being as useful, while not producing the same disagreeable effects as regards colour, smell, or spoiling linen. Hitherto he has used it only externally, but from its rapid absorption and excretion it may be used, probably with good effect, internally. How far this is the case, and to what diseases it is especially applicable, further trial must prove. At present, speaking from seventy-six cases, Kaposi has found it a useful remedy. Thus in scabies a 10 per cent. simple ointment

followed by a compound ointment of 10 parts of naphtha oil, 50 of green soap, and 100 of lard, will effect a cure in two applications. In eczema, as with tar, the exact time of application is difficult to choose; but if this be well chosen, the itching is allayed, and a slow desquamation occurs. In psoriasis a 10 per cent. ointment produces the same effect as a chrysorabin ointment, without the discoloration caused by this. The ointment has also been used with good effect in ichthyosis, seborrhœa, and pityriasis versicolor; but it is of no avail in lupus vulgaris; while a case of lupus erythematosus was advantageously treated. The naphtha oil is easily soluble in alcohol and in oils or fats, but water requires equal parts of alcohol to be added to effect a solution.—*Med. Times and Gazette*, June 4, 1881.

—

Pepsine as a Solvent in Albuminous Obstruction of the Bladder.

Dr. HOLLMANN (*Nederl. Weekbl.*, 18, p. 272) reports the case of an old man, aged 80, suffering from retention of urine, in whom the introduction of a catheter failed to procure the desired result. It was found that the bladder contained coagulated albuminoid masses, mixed with blood. A few hours after the injection of about sixteen grains of pepsine dissolved in water, a large amount of a dark, viscid, fetid fluid readily escaped by the catheter.—*London Med. Record*, June 15, 1881.

Medicine.

Changes in the Salivary Glands in Lyssa.

Dr. A. ELSENBERG (*Central. für die Med. Wiss.*, No. 13, 1881) has examined the salivary glands of twelve mad dogs and of two human subjects dying of lyssa. The principal changes in the dog were in the submaxillary and sublingual glands. The former, on section, were smooth, showed their acinous structure clearly, and were of a grayish-red colour. Under the microscope, the interstitial tissue was distinctly infiltrated with small cells with one or more nuclei, like colourless blood-cells. This infiltration was most marked around the medium-sized veins in the hilus of the acinus, diminished at the periphery, and was scarcely present at the hilus of the gland; in some places, the infiltration was of sufficient intensity to form a microscopic abscess. The fixed cells were slightly swollen, but showed no trace of division. The bloodvessels were filled with blood, containing many leucocytes, partly lying by the walls of the vessels, partly irregularly mixed with the coloured corpuscles. The alveolar epithelium, as well as the half-moon cells, were not unchanged. The contents of the secreting cells became, from a transparent mucous mass, at first slightly granular; then the granular mass gradually enlarged, while, at the same time, the circumference of the cell diminished by a third. The nucleus, from being flat, became round, enlarged, and, instead of lying peripherally, passed more to the centre. Such cells coloured readily with picrocarmin or hæmatoxylin; sometimes two nuclei were seen. The half-moon cells swelled up so as to fill two-thirds of the alveoli; at the same time their nuclei proliferated, so that each cell contained three or more times as many nuclei as a normal cell. Besides, there were sometimes in the alveoli round cells like white blood-cells, which had penetrated from the neighbouring interstitial tissue. The same appearances were found in the middle-sized ducts; the small cells, penetrating the walls, pushed up the epithelium, loosened the connection of the cells to one another, and forced them into the lumen of the duct. Around the nervous ganglia were similar infiltrations, which

sometimes penetrated the ganglia. In the sublingual gland, the changes were similar in kind but less in degree. The orbital gland in dogs, which belongs to the salivary glands, was usually very little altered. The parotid showed badly marked changes in four dogs only; the interstitial infiltration was usually moderate; the gland-cells were a little enlarged, granular, and contained two or three nuclei, and similar changes were found in the epithelium of the ducts of middling calibre. In the human subjects he found scarcely any changes in the parotid, very little in the submaxillary, which was limited to small-celled infiltration of the tissue surrounding the ducts and veins of middling calibre; the most marked changes were in the sublingual. These were less intense, but similar to those found in dogs. He concludes that these appearances are characteristic of an inflammatory process, caused by an infectious material circulating in the blood and excreted by the saliva. As the changes are most marked in the submaxillary and sublingual glands, it is probable that the saliva of these glands principally, or perhaps exclusively, secretes the specific poison. These changes are sufficiently characteristic to permit the diagnosis of lyssa in dogs, but they are too feebly marked and too like what occur in other infectious diseases, or as the result of drugs, to be of the same value in man.—*London Med. Record*, June 15, 1881.

—

Turpentine in Diphtheria.

Dr. Bosse (*Berlin Klin. Wochenschrift*, 1881, No. 9) illustrates this method by several cases. Of the pure oil of turpentine, an adult requires one large spoonful a day; children from six to twelve years, two-thirds of the same; children from one to two years, half of a large spoonful. The tolerance of this medicine is greater than might be expected. Out of eleven cases, only four vomited; if rejected, the dose must be repeated after some hours. Generally, alvine evacuations follow, which possess a penetrating odour of turpentine. After these, the general symptoms, such as fever and headache, cease. There is a rapid recovery; patients, who on the previous day took a spoonful of oil, already recovering the day after, or two days at the most, at least as regards the clearing of the throat, and the disappearance of the exudation. They would die only when assistance was rendered too late—*i. e.*, on the sixth or eighth day. Dr. Bosse attributes this effect of the oil of turpentine to its containing ozone. He denies that it has a caustic effect in swallowing, and mentions Naunyn's example, who (1868), in order to try the physiological effect of this remedy, took in company with his three assistant-surgeons 300 grammes of turpentine at one dose, 100 grammes thus coming to the share of each; no pain, except a slight headache, was experienced by these experimenters; neither albuminuria nor strangury followed.—*London Med. Record*, July 15, 1881.

—

Diphtheria in Russia.

In *Wratsch* (Nos. 49 and 51, 1880), Berg makes some remarks on 192 cases treated, in part in the ambulance, in part within the Children's Hospital at Charkow. A small number of observations are of especial value from this source, since little work has been published concerning the epidemics of diphtheria in Southern Russia, and because the cases were treated in hospital, and hence could be more carefully watched. The epidemic broke out towards the end of 1878, and continued throughout 1879. The interesting observation was made, that the number of cases always increased after a great change of temperature. Infection was usually the result of direct contact, but in one case infection was conveyed by a third person, who himself remained well. Of the

patients treated in the hospital, 41 per cent. died, this large mortality depending on the fact that a great number of them were in a hopeless condition when first seen. The majority of the children were between two and eight years of age, the percentage mortality decreasing as the age rose. Berg divides the cases clinically into two classes—1. *Slight form.* Recovery took place after four to six days, the temperature never rising above 102.7. The membrane spread equally in all directions, healing progressing from periphery to centre. The membrane was yellowish-white in colour, easily detached, and odourless. The submaxillary glands were always swollen. 2. *Severe form.* The temperature rose to 103.2°. The membrane was usually distributed bilaterally, of a dirty tint, stinking, and rapidly invading the larynx. In the majority of the cases, death occurred in five to seven days from paralysis of the heart. The invasion of the larynx often resulted from the swollen and elongated uvula coming into contact with the root of the tongue and epiglottis, and so spreading the process. In two cases hemorrhages took place beneath the skin, and in one case there was subcutaneous emphysema in the neck. The treatment chiefly consisted in painting with a 10 to 15 per cent. solution of chloride of iron in glycerine, and the use of a 5 per cent. gargle of chlorinated potass. Other drugs were tried (in three cases benzoate of soda) without good results. Pilocarpin was not tried.—*London Med. Record*, July 15, 1881.

—

Vidal's Lotion for Diphtheria.

The following formula is given in *La Presse Méd.*, May, 1881. Take 10 grammes of tartaric acid; 25 grammes of hydrolate of peppermint; 15 grammes of pure glycerine; allow them to dissolve. With a brush steeped in this lotion, the diphtheritic patches are touched every three hours. They become reduced to a diffluent pulpy mass, which is afterwards easily removed. In the interval of the application of the tartaric acid, the false membranes are touched with lemon juice. An internal stimulating treatment is prescribed, with substantial and nourishing food.—*London Med. Record*, July 15, 1881.

—

Neuralgic Character of Certain Forms of Angina, and their Treatment by Sulphate of Quinine.

Dr. R. Saint-Philippe, surgeon to the Bordeaux hospitals, points out a certain number of cases of angina observed by him, and characterized by intermittent symptoms, so that the patient scarcely suffers at all in the morning, and is the victim of intolerable pain in the evening (*Jour. de Méd. de Bordeaux*, 20 Mars, 1881, p. 371). These forms of angina, which Dr. Saint-Philippe is inclined to refer to neuralgia of the median branch of the trigeminus, are amenable to treatment by sulphate of quinine. He prescribes from 40 to 50 centigrammes (6 to 7½ grains) two hours before the attack, and obtains cure. M. Marotte published analogous cases, in 1874, in the *Bulletin de Thérapeutique.*—*London Med. Record*, July 15, 1881.

—

Doliarin as a Remedy for Ankylostomum Dubini.

Doliarin is a crystalline substance extracted from a plant native to Brazil, the *Urostigma doliarium* or *Ficus doliaria*. The juice of this plant is used there as a remedy against a disease which seems to result, like the severe anæmia of the Gothard tunnel workers, from the ankylostomum Dubini. In any case, Dr. Rozzolo has found it the most useful remedy against this parasite, although he does not deny that extract of male fern has been very successful in other hands than his.—*London Med. Record*, July 15, 1881.

Varix of the Œsophagus.

Among the extremely rare positions in which varicose veins may be found is the mucous lining of the œsophagus. An example was exhibited at the Pathological Society by Dr. Bristowe in 1856, in which "the veins of the mucous membrane were found to be enlarged and tortuous, especially in the lower part, having all the characters of varicose veins of the lower extremities." Death was caused by hemorrhage from the perforation of one of these dilated veins. C. J. EBERTH records a closely similar case in *Deutsches Archiv f. Klin. Med.* A man forty years of age had suffered for four years from hæmatemesis and bloody or tarry stools, and this had been repeated eight times within a year of his death. As there was pain over the region of the stomach, the symptoms were thought to depend upon an ulcer of the stomach. At last a fatal hemorrhage occurred, and it was then found that the veins of the mucous membrane were varicose over the lower half of the œsophagus, and that, reaching the size of pencils, they projected as soft cords from the surface. The hemorrhage was traced to an opening in one of these veins, about two centimetres above the cardiac orifice. Several minute white cicatrices were also found along the greater curvature of the stomach.—*Lancet*, June 4, 1881.

—

Typhoid Fever with Low Temperature.

FRANTZEL (*Zeit. für Klin. Med.*, Band ii. s. 217) describes severe cases of typhoid fever which attack exhausted individuals, and which run their course with low temperature or without fever, but in which occur general collapse, serious cerebral symptoms, and tendency to gangrene of the extremities, which run a strikingly acute course. Such cases indicate that high temperature is not the only cause of death in typhoid fever, but that cerebral symptoms are of great importance, and that patients even with low temperature must be carefully watched, to preserve them from the many evil consequences of even quiet delirium.—*London Med. Record*, July 15, 1881.

—

Desquamation and Infection following Scarlatina.

In the *Lancet*, June, 1881, p. 938, Mr. W. K. RIX, of the Fever Hospital, Bradford, states that in cases of fever, attended with intensely bright scarlet rash and high temperature, the desquamation may be completed in thirty days; that the great majority of cases, however, require from sixty to seventy-two days before they are fit to be discharged. In many cases, after nine weeks' quarantine, it is extremely doubtful whether the old thick skin from the heels has quite fallen off. That the dead skin from scarlatinal patients does carry infection, there appears to be little doubt; but that other factors are at work also appears certain, for frequently patients have been discharged, after all evidence of desquamation had long disappeared, the hair had been cut short, the clothes all changed, and every precaution possible taken to avoid infection, yet fresh cases have occurred within a week of the patient mixing with his brothers and sisters.—*London Med. Record*, July 15, 1881.

—

Theory of Mitral Insufficiency.

In most handbooks of medicine, in the chapter devoted to heart-affections, we find the theory of "compensation in valvular disease" based upon the law of retrodilatation and consecutive hypertrophy of the section of the heart situated above the lesion. According to this, mitral insufficiency should be followed by dilatation and hypertrophy of the left auricle, and shortly of the right ventricle

The fact that eccentric hypertrophy of the left ventricle is found in cases of simple mitral insufficiency has been frequently observed, but, nevertheless, scarcely rightly estimated.

Weil (*Berl. Klin. Woch.*, No. 7) agrees with Waldenburg in thinking eccentric hypertrophy of the left ventricle a necessary condition for efficient compensation for insufficiency of the mitral valve, dilatation and hypertrophy of the left auricle and right ventricle being of themselves insufficient to compensate for the lesion. Weil's argument is clear and simple. Mitral insufficiency is only compensated for, when, in spite of regurgitation of a portion of the contents of the ventricle into the auricle, the same quantity of blood enters the general circulation with each systole, as is the case with competent valves. Hence the ventricle must be capable of containing as much more blood as is regurgitated at each systole; as a consequence it must be dilated, and, since the work is increased, it usually becomes hypertrophied. The clinical diagnosis of eccentric hypertrophy depends on the force of the impulse and on percussion. Exaggeration of the sounds over the aortic valves may be absent, since that is merely indicative of increased tension in the aortic system. A further postulate of compensation is dilatation and hypertrophy of the left auricle, and, *hypertrophy of the right ventricle;* the latter may, however, be developed without accompanying dilatation. In proof of this, Weil has continually found eccentric hypertrophy of the left auricle, while he very commonly failed to discover any enlargement of the right heart. Exaggeration of the sounds over the pulmonary valves always existed, a sign of increased tension in the pulmonary circulation. The systolic murmur at the apex alone proves little. The existence of eccentric hypertrophy of the left ventricle with a normal pulse, allows the presumption of insufficiency of the mitral valve even before auscultation.

If with mitral insufficiency stenosis be associated, the hypertrophy may retrograde and altogether disappear, for the stenosis diminishes the amount of blood entering during diastole. The knowledge of this circumstance is the more important for the diagnosis of the combination of stenosis and insufficiency, since, in spite of serious stenoses, no presystolic murmur may exist.

If, however, on the *post-mortem* table eccentric hypertrophy of the left ventricle be seen associated with serious stenosis, it may in these cases be assumed that the hypertrophy is of older date; in fact, dates from the time when the insufficiency of the valves prevailed.—*Lond. Med. Record*, July 15, 1881.

The Treatment of Phthisis by Residence at High Altitudes.

Dr. C. THEODORE WILLIAMS, in a paper presented at the last International Medical Congress, first alludes to the effects of great altitudes (12,000 to 20,000 feet) on the human frame, as shown by the observations taken in the Alps, Rocky Mountains, Andes, and Himalayas by De Saussure, Lombard, Lortet, Marcet, Dennison, Zapatu, Jourdanet, and Henderson, and contrasts them with those of more moderate altitudes (from 4,000 to 10,000 feet), as given by Hermann, Weber, Clifford, Allbutt, Ormieux Coindet, Kellet, and others at Davos (Alps), Barèges (Pyrenees), Mexico, Blœmfontein (South Africa), and Landour (Himalayas), deducing that all advantages of mountain climates, without their disadvantages, can be obtained at moderate elevations.

Statistics are then given of cases of phthisis treated by residence at Davos, and in the South African uplands, and instances to illustrate the chief climatic effects on the various organs of the body.

Skin.—The influence on the skin is seen in the tanning of the complexion even during winter, which is due to the diathermancy of the air, and in the bracing effect on the sudoriferous glands causing cessation of night sweats.

Appetite and Weight.—Appetite is greatly increased, except in advanced cases of phthisis, and a gain of flesh (from 7 to 25 lbs.) is the result.

Muscular and Nervous Systems.—Daily exercise and frequent mountain ascents develop the muscular systems largely. The nervous system is stimulated and not unfrequently becomes over excited, and want of sleep follows, but as a rule less sleep seems necessary at high altitudes.

Temperature.—In healthy persons or ordinary chronic cases of phthisis there is little change. Where there is a tendency to pyrexia the exciting influence of the climate develops it, and if pyrexia already exists, it may increase. Mountain climates are generally contraindicated in pyrexial phthisis.

Circulation.—The first effect on consumptives is quickening of the pulse, followed later by a return to the normal rate, with a fuller vascular system, and a more powerful cardiac impulse. The pulse-rate of natives does not differ materially from that of lowlanders (Weber).

Respiration.—At the commencement of residence the respirations are more frequent than in the plains, their depth, as shown by Lortet's tracings being less; after a time they gain in depth and diminish in frequency, returning to the normal standard, as a gradual expansion of the thorax and lungs occurs. There is nothing remarkable about the respiration-rate of natives.

Changes in the Thorax.—Widening of the chest has been noted by Jourdanet and Walshe in cases of phthisis in Mexico and the Andes, by Rellet in consumptive soldiers at Himalayan stations, and by the author in cases returning from the South African mountains, by H. Weber, McCall Anderson, and the author, in patients treated at Davos.

This expansion was noticed by Dr. Ruedi in 95 out of 105 consumptives who passed the winter of 1880–81 at Davos, all stages and conditions of phthisis being here included, even some bedridden cases, and some who were losing weight. It may be concluded therefore that the enlargement of the thorax is not due to accumulation of fat and muscle, but to direct expansion of its walls from external pressure.

The amount of increase in circumference varies from 1 to 3 inches. Measurements taken at various levels, and cyrtometric tracings made by the author to determine the parts of the thorax involved in the expansion and their relation to the diseased lung, have led him to the following conclusions:—

(1) That as a rule the portions of the chest wall overlying the *healthy* lung most frequently undergo dilatation.

(2) That this may be either in an antero-posterior, or lateral direction or sometimes in both directions.

(3) It is more common in the upper regions of the thorax than the lower.

(4) That if the disease be limited to the apex of the lung, the lower portion of chest on that side may become expanded, this leading to very remarkable deformities of the thorax. Observations on the length of residence required to produce this expansion of the thorax show that this varies, but often some months are necessary for the purpose, it being dependent on the respiration rate and on the yielding or non-yielding nature of the thoracic wall.

The length of time this expansion continues after a return to low levels also varies. In one case a considerable dilatation only lasted three months after return to England, in another about six months. In the majority of cases, however, it is of long duration and probably permanent.

Changes in the Lungs.—The changes in the thorax are accompanied, or preceded by marked increase of resonance over the whole chest, diminution of dulness over the affected areas, the substitution of dry sounds for moist, and the appearance of (emphysematous) crackle around the old lesions often masking

other sounds. The tendency of cavities to contract does not seem greater than in patients treated at low levels. Over the healthy parts of the lungs the breath sound becomes harsh and puerile, the inspiration very long and the expiration short and feeble. Bronchophony and bronchial breathing become less distinct. The appearance of the thorax is striking, the intercostal spaces are hardly seen, the chest is full and well developed, but differs from the barrel-shaped form of large lunged emphysema.

The above phenomena indicate:—

(1) The development of vesicular emphysema around the affected portion of the lungs, thus localizing the disease and preventing its extension to healthy portions by infection from a caseous centre or from a secreting cavity.

(2) Absorption of some of the consolidations.

(3) The hypertrophy, or at any rate more perfect development of the healthy lung and of certain portions of the diseased one. These extensive changes in the lung-tissue necessarily lead to the dilatation of the thorax, the total result being due partly to the rarefaction of the air, and the consequent necessity at first of more frequent respirations, and later on of deeper ones, and partly to the species of lung gymnastics which the constant exercise, and especially the mountain ascents, induce.

The author is of opinion that the above constitute the principal elements in the curative process of mountain climates, but he does not undervalue the effect on the constitution generally of the dryness and purity of the air, and its freedom from septic materials.

—

Pneumothorax and Empyema.

H. SENATOR (*Zeit. für Klin. Med.*, Band ii. s. 231) brings forward four cases to disprove the current opinion that fluid effused in the course of a pneumothorax must be purulent. He insists on the frequency of bilateral pleurisy in unilateral pneumothorax, and the occurrence of late pericarditis in cases of pneumothorax. When exudation takes place in pneumothorax due to internal injury of the lung, the fluid seldom putrefies in spite of the free access of air. He urges the point, overlooked in the text-books, that pleuritic effusion in children is generally purulent. With regard to the treatment of pneumothorax he lays down these rules. 1. If only air be present, no good can be done by operative interference. 2. If fluid be also present, the fluid should be tapped, not the air. 3. If the fluid be putrid, an incision must be made. Aspiration is indicated with serous or purulent exudations in phthisical patients. He recommends that the pus should be diluted by the injecting of an indifferent fluid, so that it will run better through a fine trocar, and what is left behind will be more easily absorbed. He avoids disinfecting the pleural cavity or emptying it completely.—*London Med. Record*, July 15, 1881.

—

Stertorous Breathing in Apoplexy.

In the *Brit. Med. Journ.*, May, 1881, p. 845, Dr. ROBERT BOWLES again draws attention to the great value of position in relieving one of the most distressing and dangerous conditions of the apoplectic state, namely, stertor. [Previous papers may be consulted, *Med. Times and Gaz.*, Jan. 1860, p. 126; *Lancet*, June, 1870, p. 875, Dec. 1880, pp. 971, 1018.] If a patient with an attack of apoplexy be laid on the side paralyzed, immediately the stertor ceases, from the fact that the tongue falls on one side, allowing free ingress of air to the lung on the sound side, which is better able to carry on its functions. The cerebral circulation on the diseased side is also, by this plan, relieved from all hypostatic

congestion, and this may have a material effect in relieving the urgent symptoms. Dr. Bowles distinguishes several kinds of stertor: palatine, pharyngeal, mucous, nasal, laryngeal, and buccal stertor. Nasal stertor is readily removed by mechanically dilating the paralyzed nares. It is the pharyngeal form of stertor that so seriously aggravates the symptoms, adding suffocation to the apoplectic phenomena; and on removal of this symptom, by the simple act of change of position, the change from certain death to life is frequently obtained.—*London Med. Record*, July 15, 1881.

—

Pathological Changes in the Retina associated with Progressive Pernicious Anæmia.

In *Klin. Monats. für Augenheilkunde* (Dec. 1880), UHTHOFF describes the changes revealed by the microscope in the retinæ of six eyes removed after death from four cases of fatal penicious anæmia. They were, 1, hemorrhages, limited chiefly to the nerve-fibre and intergranular layers, and situated for the most part near the posterior pole, especially around the disk; 2 varicose hypertrophy of the nerve-fibres, affecting chiefly those of the most internal layers, so as to cause them to intrude upon the vitreous body, and consisting chiefly of the often-described shining, or finely granular masses of spherical, or spindle-shaped or retort-like form; 3, homogeneous colloid, or finely granular masses in the intergranular layer, present in one case only. It seems from these observations that progressive pernicious anæmia must be added to the list of morbid conditions which give rise to a peculiar varicose hypertrophy of nerve-fibres.—*London Med. Record*, June 15, 1881.

—

Cerebral Amblyopia and Hemiopia.

In this paper (*Brain*, part xii.), Dr. FERRIER furnishes material aid in explaining away the differences which have been hitherto apparent between the facts of clinical medicine and pathology, and those of physiological experiment, with regard to the relations of the eyes to the cerebral hemispheres. From numerous facts and arguments, the author arrives at the conclusion "that there is a twofold relation between the eyes and the cortical visual centres; the one mainly cross—the central portion of the retina probably bilaterally represented—by the angular gyrus; the other bilateral—the corresponding side of both retinæ being represented—by the occipital lobe, not alone, however, but in conjunction with the angular gyrus." From the nature of the impairment of vision existing in cerebral hemianæsthesia of organic origin, and which is due to lesion of the posterior segment of the internal capsule, external to the optic thalamus, the author concludes that the fibres which pass through the segment are specially in relation with the angular gyrus, and represent the opposite eye as regards those functions which are affected in hemianæsthesia. In cases of hemiopia, where central vision is retained for some degrees on all sides of the point of fixation, Dr. Ferrier considers that the cause is cerebral, not peripheral. In relation to this subject, numerous cases are discussed, and three unpublished ones are related.—*London Med. Record*, June 15, 1881.

—

Treatment of Epilepsy.

Dr. LASKIEWICZ (*Przeglad lekarsk.*, Nos. 4 and 6, 1881, *Centralblatt für Nervenheilkunde*, 1881, No. 6) commences the treatment of epileptic patients with bromide of potassium, of which a solution of one gramme is best given in the evening. As often as the attacks are repeated, the dose is increased one gramme daily, until 20, 25, and even 30 grammes are reached. The author

mentions a case in which as much as 60 grammes per day was given for some time. This remedy is very differently tolerated. The largest dose which has had an effect is to be continued for months and years, and then diminished with great care. Probably the patient will then be free from future attacks. If the remedy be not tolerated, atropine must take its place. This it is best to give as an alcoholic solution: 8 centigrammes of sulphate of atropine in 20 grammes of alcohol; this to be kept well closed in a glass. The dose is increased from one to ten drops, the largest dose for adults being twelve drops per day. It will be best to give it in milk or soup, about one hour before or after breakfast. The alkaloids of coffee, cocoa, or tea diminish the effect of atropine.—*London Med. Record*, July 15, 1881.

—

Compression of Carotid in Trigeminal Neuralgia.

Dr. SEIFERT (*Berlin. Klin. Wochensch.*, 1881, No. 11) publishes three cases of trigeminal neuralgia, in which he successfully employed compression of the carotid, as recommended by Gerhardt. The compression was made to last from fifteen seconds to one and a half minutes, and repeated as often as the pain was interrupted, while arsenic and quinine were likewise administered. Gradually, the intervals were lengthened.—*London Med. Record*, July 15, 1881.

—

Schiller on a Case of Catalepsy with Speech-reflexes.

SCHILLER (*Bres. Aertzl. Zeit.*, 1780, No. 21, and *Central. für die Med. Wiss.*, 1881, No. 17) reports the case of a previously healthy girl, aged 10 years, who became suddenly unconscious; the night before she had complained of stomach-ache, which had disappeared in the morning. The limbs could be moulded into any positions, and, in spite of their inconvenience, retained these for some time, and then gradually sank down again. Stroking from below upwards in the umbilical region made the child give a peculiar cry, which was not caused by deeper and sharper pressure on the same place. Also touching a place close to the manubrium sterni caused a peculiar cry. Strong electrical stimulation (the electric brush) and a vinegar enema, cured her after the lapse of one hour and a half. On other days, there were symptoms of commencing chorea in the facial muscles and fingers, which afterwards disappeared. The child has remained quite well for more than six months since the attack, of which she retains no recollection.—*London Med. Record*, July 15, 1881.

Formation of Trichinæ Cysts.

The mode of formation of the cysts of trichina has been studied by M. CHATIN and described in a communication to the Académie des Sciences. It was formerly said to be formed partly from the contractile tissue, and partly by a secretion from the nematoid, but this opinion was based only on some apparent differences in the thickness or aspect of the cyst wall, and not on any careful study of its formation, which necessitates the examination of animals dying or killed in different stages of the affection. When it arrives in the muscles the worm forms adhesions with the interfascicular tissue in which rapid changes occur. The elements increase in size, and during the growth of the protoplasm it assumes the appearance of an amorphous mass, in which, however, nuclei and vacuoles can be seen, which seem to indicate that the mass consists really of aggregated cells. By the growth of this the primitive fibres are compressed. In the new protoplasm fine proteoid granulations are first observed, and then other granulations which present all the reactions of glycogen. Then follow important changes in the periphery of the

granular mass containing the trichina now curled up in the interior; the outer surface becomes distinctly thickened and indurated, and may then become lamellated or present granulations or folds. The sarcolemma takes no part in the formation of the cysts except occasionally furnishing it with a purely adventitious layer. Moreover, when the nematoid contracts its first adhesions to the sarcolemma, and not to the interfascicular tissue, it rapidly dies without determining a new formation.—*Lancet*, July 30, 1881.

—

The Need of Revaccination.

Dr. RENNER, in a communication to the *British Medical Journal* of June 4, 1881, shows in a very conclusive manner the very highly unprotected state of the adult population against smallpox, owing to the neglect of revaccination. In eighty-one cases in which persons had not been revaccinated since the first vaccination in infancy, ninety per cent. of the revaccination with calf-lymph proved successful; showing that, in ninety per cent. of those persons, the protection afforded during early life had worn out, and the necessary protection to be obtained by revaccination after the age of fifteen had been neglected, until the present alarm, owing to the epidemic prevalence of smallpox, had reminded them of the extreme danger of such neglect. As a matter of fact, it is essential, as a protection of the population from smallpox, that each individual should be successfully revaccinated after the age of fifteen. The rule is very simple, and the evidence overwhelming. Our soldiers, sailors, postmen, smallpox nurses, all of whom are revaccinated, enjoy an almost absolute immunity from smallpox, even during epidemic periods, and when surrounded with disease. The like immunity may be obtained by every rational member of the community who chooses to submit himself after the age of fifteen to revaccination. The present epidemic of smallpox is a lamentable monument of the human folly and neglect, which leave out of view a harmless and necessary precaution against so fatal and loathsome a disease. The responsibility of the misguided persons who seek to deter from obtaining this protection is great indeed; and it is difficult to use words of moderation in viewing all the fanatical ignorance and obstinate perversion of the truth of the facts with which they stimulate and maintain their reckless and mischievous crusade.

—

Ainhum.

Dr. FRANCIS GUYOT (*Le Prog. Méd.*, 1881, No. 19) gives a description of this peculiar tropical disease, and adds four cases observed by himself. It is met with in North Africa, in Southern India, Central America, and some of the Pacific islands. It affects generally the fifth toe, but sometimes the fourth, and more rarely many or all the fingers and toes. The chief symptom is an annular groove round the affected member, deeper on the palmar or plantar surface, growing deeper as it advances until amputation results. The surface of the fissure is normal; sometimes it is bathed in serous fluid, sometimes the segment above the fissure becomes swollen. In some cases the tissues of the stump are normal, more often atrophied or undergoing fatty degeneration, but preserve a healthy nucleus. There is neither inflammation, constitutional reaction, nor pain. It lasts often many years. It has no ultimate bad effects on the general health. The negroes attribute it to a parasite, but there is no evidence in favour of this view. Females do not escape. Consanguinity probably plays some part. No treatment is of use, though Da Silva Lima cured one case by an incision at right angles to the groove.—*London Med. Record*, July 15, 1881.

Antiseptic Inhalations in Pulmonary Affections.

Dr. J. G. SINCLAIR COGHILL, in the *Brit. Med. Journ.*, May, 1881, p. 841, has an interesting paper upon the value of antiseptic inhalations in all lung affections characterized by purulent expectoration. By this means we are enabled to dispense with cough-mixtures by arresting the secretion of the sputa; for, if sputa exist, cough must necessarily follow, and it is dangerous to arrest the cough under such circumstances. Dr. Coghill finds the following formula good: ℞ Tincturæ iodi etherealis, acid carbolici, āā ʒij; creasoti vel thymoli, ʒj; spiritûs vini rect., ad ℥j; M. If the cough be urgent, or breathing embarrassed, chloroform or sulphuric ether may be added at discretion. The mode of inhaling is most important. The patient should be carefully instructed to inspire through the mouth alone, and expire through the nose, as, by this means, the medicated air is forced into the remoter air-cells.—*London Med. Record*, July 15, 1881.

Surgery.

Removal of the Entire Tongue through the Mouth by Scissors..

In the Section on Surgery of the International Medical Congress, Dr. WALTER WHITEHEAD read a paper upon the removal of the tongue through the mouth with scissors, and gives the details of the operation. He says, "On November 3d, 1877, I removed the whole of the tongue through the mouth with scissors. (Vide *British Medical Journal*, 1877, Dec. 8, p. 303.)

"This case, to the best of my knowledge, was the first instance of the entire tongue having been removed for disease through the mouth by simple excision.

"More than thirty tongues have since been removed by the same plan.

"The operation is conducted in six stages after the following simple manner: 1. The mouth is opened to the full extent with a suitable gag; and the duty of attending to this is entrusted to one of the two assistants required. 2. The tongue is drawn out of the mouth by a double ligature passed through its substance an inch from the tip. 3. The operator commences by dividing all the attachments of the tongue to the jaw and to the pillars of the fauces. 4. The muscles attached to the base of the tongue are then cut across by a series of successive short snips of the scissors until the entire tongue is separated on the plane of the inferior border of the lower jaw, and as far back as the safety of the epiglottis will permit. 5. The lingual or any other arteries requiring torsion are twisted as divided. 6. A single loop of silk is passed by a long needle through the remains of the glosso-epiglottidean fold of mucous membrane, as a means of drawing forwards the floor of the mouth should secondary hemorrhage take place.

"The patient is fed for the first three days by nutritive enemata; satisfying thirst by occasionally washing out the mouth with a weak iced solution of permanganate of potash. The difficulties and dangers of the operation are few. Hemorrhage is easily controllable. I have twice removed the entire tongue without having to secure a single vessel, and more than once have only had to twist one lingual artery.

"A table of twenty-eight cases, with one death the immediate result of the operation (an old man æt. 62), accompanies the paper. Two other deaths occurred in consequence of the operation, but from remote causes.

"Taking the most unfavourable estimate, the deaths in the twenty-eight cases do not amount to 11 per cent., and, when contrasted with the 30 to 60 per cent. of deaths resulting from removal of the tongue by any other operation, I venture

to affirm that substantial evidence has been submitted in favour of the removal of the tongue with scissors."—*Official Abstract of Proceedings International Medical Congress.*

—

Suprapubic Lithotomy.

In a recent contribution on "Lithotomy and Antisepticism" (*Archiv für Klin. Chir.*, Band xxvi., Heft 1, 1881), Dr. CARL LANGENBUCH of Berlin advocates the high (suprapubic) operation. In perineal lithotomy, the antiseptic method cannot be rigorously carried out, in consequence of the proximity of the anus, whilst in the high operation this method is applicable under very favourable circumstances. The risk of wounding the peritoneum in this latter operation is not so great as is generally supposed, since out of 478 cases of suprapubic lithotomy collected by Dr. Dulles, in thirteen only had this membrane been wounded, and of these three cases were fatal. It was shown also by the same author that any stone weighing more than two ounces could be removed with less risk by the high than by the perineal operation. This latter proceeding, however, in Germany, as in other countries, has long been almost exclusively favoured, high lithotomy having been resorted to in some few cases of very large and very hard stone.

The author considers whether this preference of perineal to suprapubic lithotomy can be supported by anatomical and physiological data and by clinical experience. Urinary infiltration of connective tissue, it is pointed out, is a danger common to both operations, which, however, in the suprapubic proceeding can be prevented. The danger of this infiltration, when it has occurred, is much less after the high than after the perineal operation, since the epi-cystic is more accessible and less confined than the peri-prostatic and circum-rectal connective tissue, can be more readily incised and disinfected, and, as it is not connected with any large venous plexus, is less likely through its decomposition to set up general septic infection. In the high operation, the incisions can be made carefully and precisely, and through structures that are freely exposed to view, and there is no necessity for forcible laceration and contusion of connective tissue and other soft parts. It may be said, the author suggests, that it is as difficult to set up urinary infiltration after the high operation, as it is to prevent such infiltration after lithotomy by the perineum.

In the high operation, when successfully performed, the only structures that are incised are integument, cellular tissue, and the wall of the bladder; all which structures are capable, after healing, of performing their physiological functions. In perineal lithotomy, on the other hand, many vascular and glandular structures must necessarily be wounded, and some of these are liable to be permanently injured. The latter operation may, it is true, be very often considered as successful; the stone has been removed, and the patient recovers; but it cannot be denied that it is often followed by one or more of such results as urethral stricture, incontinence, impotence, urinary fistula, recto-vesical fistula. With regard to the danger of wounding the peritoneum in the high operation, it is stated by the author that the topographical conditions of the para-cystic peritoneal fold in adults are not so unfavourable as is commonly supposed. Petersen of Kiel has shown by recent experiments on the dead body that, though the bladder is inaccessible when empty, yet, by the injection of water into this viscus and also into the rectum, the peritoneal reflexion can be elevated to an average distance of one inch and a third above the upper margin of the symphysis pubis. In a smaller series of experiments, Langenbuch has been able, by extreme distension of the bladder by injected fluid (800 to 1000 cubic centimetres), to raise above the symphysis from two inches to three inches and a third of uncovered vesical wall. In

some of these experiments, it is stated that the bladder was filled almost to the point of bursting. With this question two factors, one negative, the other positive, come into play. In cases of calculous impaction at the neck of the bladder, especially when the stone is large, it will often be found impossible to introduce any quantity of fluid into this viscus. On the other hand, there is no necessity for free incision into the bladder, since the vesical wall, unless much thickened, is very elastic, and a small orifice can be readily dilated by traction in different directions. Langenbuch concludes that in ordinary cases sufficient room can be obtained above the symphysis for the performance of the high operation, by injecting the bladder, or, if this cannot be effected, by distending the rectum.

The risk of wounding the peritoneum in the high operation is no reason, Langenbuch holds, for preferring perineal lithotomy in these days of antiseptic surgery, when many laparotomies are performed yearly with little mortality. Much depends on whether the peritoneum be wounded before or after incision of the wall of the bladder. In the former, no danger is likely to result if the operation be performed under antiseptic conditions, and if the opening of the bladder be postponed for a time, and until after the cicatrization of the superficial wound. If the peritoneum be accidentally wounded after the vesical wall has been incised, then there is great risk of decomposed urine passing into the abdominal cavity and setting up fatal peritonitis.

For the removal of a large stone—one with a maximum diameter of about two inches—the safest proceeding, Langenbuch thinks, is the high operation performed in two stages, and under strict antiseptic conditions. To meet the case of a monster stone, measuring from four to seven inches in diameter, the extraction of which in the second stage of the high operation would probably cause much laceration of the recently healed superficial parts, and also of the peritoneal fluid, he proposes a complicated proceeding. A description is given of a high operation in two stages. In the first stage, the anterior surface of the bladder is freed to some extent of its layer of peritoneum, and a plastic operation is performed on this membrane. In the second stage—that of extraction performed after an interval of from five to eight days—elaborate precautions are taken to disinfect the bladder.

Dr. Langenbuch does not undertake in this paper to discuss how far the indications for lithotrity might be modified by a general acceptance of his proposed antiseptic high operation performed in two stages, but points out that, in the first place, the invention and development of lithotrity are due to the dangers of lithotomy, and that, in the second place, the former proceeding, as is well known, is not free from danger, nor capable in every case of effecting complete cure.—*London Med. Record*, June 15, 1881.

—

Treatment of Blood-Cysts of the Thyroid Gland by Electrolysis.

M. Berger, in the name of M. Onimus and himself, read a communication on this subject at the last meeting of the Paris Société de Chirurgie (*Bull. Gén. de Thér.*, May 15, 1881). A lady had suffered for a year and a half with a tumour on the left side of the thyroid gland, and, latterly, it had rapidly increased in size. The first puncture was almost immediately followed by a relapse. The tumour rapidly became as large as an apple; it was movable, colourless, fluctuating, and already gave rise to disturbances in the action of the air-passages. M. Onimus proposed to treat it by electrolysis. On the 30th of January, MM. Berger and Onimus made a puncture, which gave issue to about 150 grammes of a chocolate-coloured liquid. A carbolated injection was then made by the channel; then an injection of a solution of iodide of potassium of ten degrees of

strength. There was then introduced into the cystic cavity, filled with this solution, a metallic stem placed in communication with the positive and negative poles of the electric pile, of from 24 to 36 elements, whilst the other pole was applied on the periphery. There was a little hemorrhage. In a short time the cavity refilled itself, and the tumour was as large as ever. The day after the operation there was an attack of intermittent fever, which was only one of those diathetic reminders pointed out by M. Verneuil. M. Berger gave up the patient five months ago, being persuaded that it was a bad case. Four weeks ago he discovered that from the size of an apple the tumour had become reduced to that of a nut, and since that time it had decreased in considerable proportion. M. Boinet also related several cases in which he obtained excellent results after puncture, followed by the iodized injection. It was a mistake to believe that the iodized injection was also followed by acute inflammation, for in the cases to which he alluded there was neither inflammation nor suppuration. M. Delens remarked that he could not quite understand the curative action of electrolysis in M. Berger's case. The treatment was complex; there had only been one application. Generally the action of electrolysis was much more slow, and it was necessary to repeat it frequently. M. Desprès pointed out that there were serous cysts with thin walls, which were cured with one simple puncture, and there were others with anfractuous walls, with syrupy and sticky contents, on which treatment was excessively difficult. In fact, in these cases the iodized injection did not succeed better than anything else. M. Le Dentu agreed with the last speaker as to the fact that there were mild cysts, and there were others in which the treatment was very difficult. It was not always easy to ascertain which variety was present. A puncture was made, blood flowed, and sometimes there was great difficulty in arresting the hemorrhage. The therapeutic treatment should therefore be varied according to the cases in serous cysts. The iodized injection left excellent results in sanguinous cysts. There was often a gangrenous inflammation, which might go on to elimination of the sac. The effect of electrolysis had yet to be determined. M. Berger concluded by owning that he was opposed to iodized injection, but he believed that in certain sanguineous cysts electrolysis brought on coagulation.—*London Med. Record*, July 15, 1881.

Symptomatology of Mediastinal Tumours.

A. SCHREIBER (*Deutsches Archiv für Klin. Med.*, Band. xxviii. s. 52, *Central für die Med. Wiss.*, No. 17, 1881) bases his remarks on four cases observed in Ziemssen's clinic. 1. A girl, aged 21, complained for some months of palpitation and breathlessness. There were physical signs of left-sided pleuritic effusion; later on, a peculiar dulness developed, which began at the right costal cartilages and ran across the sternum to the left anterior axillary line, then downwards and backwards, and finally, horizontally to the spine. The pleura was punctured many times with temporary benefit. There were then some difficulty in swallowing, and slight right-sided pleuritic effusion. There was a fibro-sarcomatous tumour as large as a man's head. 2. A baker, aged 17, complained for eight days of cough, pain in the chest, and loss of appetite. The expression of his face was anxious, the skin was yellowish, the veins of the neck were distended. He had a barking cough. There were paralysis of the right vocal chords, and multiple swollen lymphatic glands. He had slight fever. Later on there was increased glandular swelling, especially along the lower border of the pectoralis major. He had increasing breathlessness. There was dulness above the heart, reaching up to the clavicle and to the axillary line. Section showed a round-

celled sarcoma of the anterior mediastinum, with numerous metastases which pressed on the vena cava and recurrent nerve. 3. This case was that of a woman, aged 35, with diffuse fibro-sarcoma of the mediastinum, which led to metastases in the lungs, and to closure of the vena cava and subclavian vein. 4. A peasant, aged 31, had been ill eight and a half years. He was breathless and had swollen veins on the thorax. There was a resistant tumour in the left supraclavicular region. He had œdema of the face. There was protrusion of sternum and superior thoracic region. There was absolutely empty note over the whole sternum and along the right sternal border. The dulness was limited to the left by a line drawn from the attachment of the third rib, outwards and downwards to a centimetre outside the nipple.—*London Med. Record*, July 15, 1881.

—

Causes of Death from Burns.

LESSER (Virchow's *Archiv*, Band lxxix.) first of all combats the deductions drawn by Sonnenburg from his experiments (*Deutche Zeitsch. fur Chir.*, Band. ix.), and, supported by his own experiments, conclude that irritation of the terminations of the cutaneous nerves is of no special importance in death rapidly following burns. He then passes on to demonstrate the changes which take place in the blood circulating in the skin in burns of the surface of the body; and further, the changes induced in the body by these alterations. He has come to the conclusion that (apparently without essential destruction of the red corpuscles) the red colouring matter of the blood becomes diffused in the plasma. He proves this by transfusing defibrinated blood heated to above 70 deg. Cent. (158 deg. Fahr.), as well as that of previously burned animals. The diffused colouring matter is chiefly excreted by the kidneys in the urine, as is evident from examination of the urine and kidneys. The excretion begins about an hour after the burning, and may continue as long as two days. On *post-mortem* examination, extravasations of blood were discovered in various organs, and in the kidneys large collections of blood-colouring matter especially within the convoluted tubes, pigment-granules between the epithelium, hyaline cylinders, etc. On the ground of previous, as well as some more recent, experiments, Lesser discusses the possible causes of death; and, after eliminating numerous possibilities, advances the theory that a relatively too large number of red disks (through separation of the blood-colouring matter and consecutive damage) become fully developed, so that a sufficient quantity of blood for the completion of the respiratory processes necessary for the prolongation of life is no longer furnished, and, as a consequence, paralysis of the respiratory and circulatory centres ensues.

Lesser thinks that the injurious effects of burns on the general system depend neither on the thickness and capacity for resistance of the skin, the extent of the burned region, nor on the intensity or length of the operation; but that for seriousness of the burns it is necessary that the circulation should be kept up in the burned parts, and that new masses of blood should constantly stream through the heated skin and muscles; the longer this is continued, so much the greater being the number of the red corpuscles robbed of their vitality. At a later period, death may result from septicæmia.

Lesser speaks strongly in favour of the method of treatment already recommended by Ponfick for severe burns; viz., transfusion, in addition to local antiseptic treatment, and is of opinion than transfusion may still be useful at a later period, if the patient do not recover his strength.—*Lond. Med. Record*, July 15, 1881.

Rupture of the Bladder.

In a paper read at the German Medical Society of St. Petersburg (*St. Petersburg Med. Woch.*, June 11), Dr. ASSMUTH stated that he had brought forward two cases of rupture of the bladder from muscular exertion in consequence of the rarity of the accident; for, although these two cases were admitted into the Obuchow Hospital in two successive years (1879 and 1880), yet Bartels, in his monograph on the subject, states that among 10,867 surgical cases, treated at the Bethanieu in Berlin (1869–76), only three cases of rupture of the bladder occurred, and in 16,711 surgical cases at St. Bartholomew's only two cases occurred. Of the 169 cases collected by Bartels, not one arose from mere muscular exertion.

The subject of the *first* case was a man, thirty-two years old, who, while removing a heavy sack of flour from a railway platform to a cart, was seized with a violent pain in the hypogastrium. Trying some time after to make water, he only passed a few drops of blood. He came to the hospital on foot two days afterwards. His pulse was then 88, and his temperature 37.7° C. There was great tenderness in the hypogastrium, and a catheter only withdrew a few drops of blood. His general condition, and the apparent absence of any cause for it, prevented the diagnosis of a ruptured bladder, which the local symptoms would have justified. He soon, however, became much worse, and died on the sixth day after the accident, without having passed a drop of urine. The autopsy exhibited recent general peritonitis, and a rupture, two centimetres and one-third in length, at the upper part of the posterior wall of the bladder, a little to the right of its apex. The *second* case occurred in the person of a man forty years of age, who, two days prior to admission, had been seized with a violent pain in the hypogastrium while endeavouring to raise a very heavy burthen. He died on the sixth day after the accident. Peritonitis with purulent exudation was found, together with a rupture, three centimetres in length, at the right side of the posterior wall of the bladder, about two centimetres from the apex. The mucous membrane of the bladder was quite normal in appearance, and no trace of coagulum was found within the organ or in its vicinity. Of the urine, which during life had in both cases collected in the right hypogastrium, there was but little found after death, it having evidently become diffused by the intestinal movements. The local tenderness in that region became less concentrated in that spot; and after death a diffused peritonitis was found to be present.

In both these cases the muscular exertion required to raise a heavy burthen was obviously the cause of the rupture, and although hitherto no example of such an occurrence has been published, yet an analogous action in the production of fractures and dislocation is not rare. Although both patients denied that the urine had been long held in the bladder, there can be little doubt that considerable distension must have existed. In practice we frequently meet with very erroneous statements as to the fulness of the bladder, and that not only from defective self-observation, but also from impaired elasticity of the walls of the bladder, preventing a right judgment being formed as to its distension. In both cases the localization of the rupture of the bladder was the same; and Dr. Assmuth deduces from Hyrtl's descriptlon of the anatomy of the bladder that this was at the feeblest part of the organ.—*Med. Times and Gazette*, July 23, 1881.

Cancer of the Breast and Meninges.

The following case is related by Dr. OTTO LUND, in the *Norsk Magazin for Lägevidensk* for 1880. A woman, aged 59, was operated on, in October, 1869,

for a cancer of the right breast; and in November, 1876, for a cancerous infiltration of the glands in the right axilla. In the interval, three years after the first operation, the patient—who was said to have suffered several times while young from convulsions and attacks of giddiness, and afterwards also from migraine—was again seized with giddiness, which came on, or was made worse, when she turned her head to the right, while lying in bed. The attack of giddiness passed off gradually; but, after some years, she had sciatic pains in the left lower limb, and periodical pains in the right half of the forehead, and in the right temple, with tenderness on pressure. There was no disturbance of intelligence; weakness of memory was first observed in 1880. In February she had an epileptiform attack, with loss of consciousness and tonic convulsions, during which the head and eyes were turned to the right side; after the attack, there was found to be paralysis of the upper and lower limbs. The intellect also became disturbed; and she died on March 29th, fourteen days after a similar attack to that above described. On *post-mortem* examination, a cancerous nodule, of the size of a nut, was found in the left breast (this had been observed during life); there were two disk-shaped cancerous growths, respectively 5 and 3 centimetres (2 inches, and 1.2 inches) in diameter, and about half a centimetre thick, in the arachnoid in the right parietal region, and a smaller similar tumour on each side of the crista galli. There was fatty degeneration of the heart.—*London Med. Record*, June 15, 1881.

—

Of Syphilis Fungus.

Dr. BERMANN of Baltimore describes (*Archives of Med.*, Dec. 1880, p. 263) certain microscopic growths which he found in syphilitic primary sores, and which he believes to be peculiar to that disease. The author begins by quoting Klebs's experiments on the subject, and states that, before the publication of that observer's views, he had already discovered certain fungoid growths in a freshly excised prepuce obtained from Zeissl. What first attracted Dr. Bermann's attention was a singular collection of micrococci and fungoid growths, firmly adhering to and partly filling up the lumen of most of the lymphatic vessels. Some of the arteries also contained these growths, intermixed with blood-corpuscles. The growths were found in all the hundreds of sections made by the author. The micrococci are small, strongly refracting spherical bodies, and resemble those illustrated by Klebs; but the bacteria, described by the same observer, Dr. Bermann found only in a few instances, and then only in the arteries. The principal changes take place in the lymphatics, and chiefly in those at some distance from the initial sclerosis, which explains, according to the author, why others have been unsuccessful in discovering these organisms.—*London Med. Record*, June 15, 1881.

—

Case of Hepatotomy for Hydatids.

Mr. LAWSON TAIT, in a communication to the *British Medical Journal* for July 16, 1881, says: "The following notes briefly give the details of the sixth case of this operation which I have performed; and, like the others, it has been remarkable for the speedy and complete recovery of the patient from the operation, and the thorough cure of the disease from which she was suffering.

"A. M. S., aged 7, was admitted to the Women's Hospital early in May last, suffering from severe symptoms due to a tumour which existed on the right side and above the level of the umbilicus, which was clearly cystic, and in all probability connected with the liver. It gave the patient great pain; and I diagnosed it to be a hydatid tumour of the liver. She had been under the care of my friend

Dr. Welch at the Children's Hospital, who has kindly favoured me with the following notes.

"The child never was strong; on the contrary, she had always been regarded as delicate. A year ago, her mother noticed that her motions were rather white-coloured. A swelling was noticed in the abdomen about November last, and she complained of pain across the back and shoulders. When she was admitted to the Children's Hospital, in December, 1880, there was a firm tumour just below the ensiform cartilage, the dulness extending round the side. It was noticed in February that there were some nodules on the surface of the liver, also that the tumour was more freely movable.

"When she was admitted to the Women's Hospital, under my care, she had a tumour about the size of a fœtal head, which was extremely tender to the touch. The child was very sick and ill, and altogether her appearance warranted interference. I therefore opened the abdomen on May 20th, making an incision about three inches long, an inch and a half to the left of the umbilicus, the lower end corresponding to the umbilical level. When the cavity was opened, it was perfectly clear that the tumour was situated in the liver, and was a hydatid cyst. I removed from it, by means of an aspirator, about twenty-six ounces of clear fluid containing a large number of scolices. I then enlarged the aperture in the liver to about an inch and a half, and secured its edges to the edges of the parietal wound by means of a continuous suture, and fastened in a wide soft India-rubber drainage-tube about six inches long. She went on perfectly well; her severe symptoms were immediately relieved, and on May 26th the mother-cyst came away entire. The drainage-tube was removed on May 30th; and on June 2d she left the hospital with the wound quite healed, having gained greatly in weight, and having acquired a perfectly healthy appearance.

"No attempt was made to conduct the case upon Listerian principles, the only dressings used to the wound being lead lotion and absorbent wool."

—

Treatment of Intra-Thoracic Suppurating Hydatid.

At the April meeting of the Medical Society of Victoria, Dr. S. D. BIRD reported two cases in which intra-thoracic hydatid cysts, which had advanced to the stage of death and decomposition, were got rid of by incision between the ribs. Such treatment is, of course, a more complete and radical cure than any system of tapping, injection of parasiticide fluids, or electricity can be, as the latter always leave with the cyst the possibility of its refilling if its vitality is not completely destroyed, of which we cannot be absolutely sure. On the other hand, extraction is a much more serious operation, and one that requires considerable time and patience for its successful accomplishment, as well as the existence of certain conditions without which such a procedure would be hardly allowable.

To my mind the conditions that justify incision between the ribs, with the view of extracting hydatid cysts, are—*First*, any case of hydatid in the pleural sac, in which situation the cyst always enlarges with great rapidity, and even when emptied of its contents, or dealt with in any way short of removal, remains a permanent source of irritation to the serous surface, with consequent pleuritic pains, febrile irritation, and even inflammatory effusion. The question now naturally arises as to the possibility of the differential diagnosis of pleural hydatid from one in the lower lobe of the lung, or in the convex surface of the liver, especially on the right side. In most cases it will be very difficult to decide before operation, the only special physical sign of pleural hydatid being that the usual rounded area of dulness is to some degree alterable by change of position, which is not the case if the cyst is embedded in the lung substance. In my cases

the pleural cyst has always been loose, and has not contracted adhesions to the serous surface.

The *second* set of cases demanding incision and extraction are those of large old suppurating cysts of the lung which have generally found their way into a bronchus, and fragments of cyst and fetid pus are being constantly expectorated with great labour and distress to the patient. Such cases are generally in the lobe, and if of long standing, adhesions will almost certainly be found to have taken place, so that the operation will be comparatively safe and easy. I have seen over a dozen of such cases, and in no one has the result been other than completely successful. I shall now proceed to read notes, hitherto unpublished, of two cases, one of pleural and the other pulmonary hydatid, treated in this way.

Mrs. G., æt. 26, married lady with two children, native of a neighbouring colony, consulted me for a condition which had been diagnosed variously as pleurisy with effusion, enlargement of the liver, and abscess. On examination, the right side measured one and a half inches larger than the left, intercostal spaces not bulged. There was no febrile pleuritic history, but she described stitchy pains all over the side of a distinctly pleuritic character, and also pains in the point of the shoulder that were suggestively hepatic. On percussion and auscultation the question of pleuritic effusion was set at rest, as the rounded area of dulness characteristic of hydatid presented itself in the lower part of the right chest, while the breath sounds and percussion note at the apex were normal, even when the hips were raised above the level of the thorax. The rounded dull area shifted a little with gravitation in this position, but hardly enough to convince either the late Dr. Martin (who consulted with me) or myself, of the diagnosis of pleural hydatid absolutely, for of course a large cyst in the convex surface of the liver would shift and alter the relations of the diaphragm to its parallel ribs by the weight of that heavy bulky viscus in the inversed position of the body. In any case, it was determined to introduce a trocar, which was done in the seventh intercostal space, when three pints of semi-purulent fluid escaped, showing plenty of hooklets on microscopic examination. Not much relief followed, and there was ill-defined dulness about the base of the right lung, with pleuritic stitches, and persistent high pulse and temperature, evidencing a local source of irritation in the pleura. Feeling convinced now that the case was one of pleural hydatid, I determined, with the concurrence of Dr. Martin, to remove it, as the only method of accomplishing a cure. On the tenth day after the first tapping, I made a free incision between the seventh and eighth ribs at the same position, and accordingly removed, without any difficulty, a large semi-decomposed hydatid cyst, broken into several fragments. The site was now beyond doubt, for I passed my little finger through the wound, and felt the round surface of the liver through the thin interval of the pleura and diaphragm. A few ounces of pus and broken-down fragments of hydatid followed the main cyst, and then rather a free discharge of venous blood, which, however, soon ceased. I left a piece of drainage tube in the pleura as a precaution. The patient experienced the greatest relief from the operation; the febrile symptoms and pain all left her, and the physical signs gave no evidence of any further foreign body in the cavity of the thorax; in fact, for several days everything promised a speedy recovery. I had the advantage of Mr. Fitzgerald's opinion on the case, and he concurred in the diagnosis and treatment. However, about a fortnight after the removal of the cyst, the patient began to complain again of dyspnœa and oppression of the chest, and on exploring the cavity of the pleura with an elastic catheter, to my great disgust I burst into another cyst, from which ran about ten ounces of perfectly clear hydatid fluid, swarming with echinococci in full vigour and vitality. I succeeded

in removing this cyst also, and irrigated the pleura frequently with weak solutions of iodine, with a view of destroying any lurking ova. Again great relief followed, but the poor patient was doomed to be the victim of the parasite, for soon heart distress commenced, exactly similar to that experienced by another case of pleural hydatid recorded by me in my pamphlet on this subject.

Sudden and alarming attacks of dyspnœa, generally ending in syncope, with cardiac murmurs terribly jumbled and confused. These symptoms increased in intensity till in one of them the poor lady died suddenly, the pleura and lung being apparently quite restored to their normal condition. Unfortunately there could be no post-mortem, but I have no doubt that the cause of death was hydatid of the pericardium, similar to that in my other patient, a preparation of whose heart is in the University Museum. It seems almost as if, when hydatids attack one serous sac, similar cavities are more attractive to them than the solid viscera. A very remarkable feature in these two cases was the extraordinary rapidity with which the new cysts developed in the pleura and pericardium, a few days only being sufficient to cause urgent symptoms in one case and death in the other.

The other case being one of hydatid of the lung substance had a more happy result. A girl nine years old was brought to me by her parents from a township in the northeastern district, about seventy miles from Melbourne. She was excessively emaciated with intense hectic and rapid pulse. Cough constant and violent, with expectoration of pus and fragments of cyst of horrible fetor. She was only able to breathe in one position, lying over and partially prone on the affected side. Any change from this caused alarming symptoms of suffocation, and as the poor child had been in the same state for over two months bedsores on the side were very distressing. A large trocar introduced between the fifth and sixth ribs gave exit to many ounces of fetid pus and fragments of cyst, giving great relief. After two days I enlarged the opening, and succeeding in removing the parent cyst, and left a piece of drainage tube in the nidus of the parasite which was frequently washed out with weak solution of Condy's fluid. In less than a month from her arrival the child returned to her home in perfect health, the wound having healed up from the bottom. I rather pushed on the treatment in this case as the symptoms were so urgent, but I am convinced that in the majority of cases one of the great factors of the constant success that attends them is to take time over the different steps of the operative procedure, so as to allow the lung time to expand, especially in adults.—*Australian Medical Journal*, April 15, 1881.

Early Resection in Tuberculous Disease of the Joints.

Dr. KÖNIG, of Göttingen, in a paper read before the recent congress of German surgeons, ascribed only a limited value to early resection in tuberculous disease of joints. In a case of white swelling of the knee, with fistulæ and abscesses, he had obtained a cure by expectant treatment; and, in a case of coxitis, with large abscesses reaching to the middle of the femur, he had laid the parts freely open, and scraped the bone, without any disturbance of motor power. He had also acted in the same way, producing only slight impairment of motion, in a case of contraction of the adductor muscles, with a slight shortening of the limb. It was only when the patient's general condition was seriously implicated by the local disease, or when there was danger of the occurrence of this, that resection should be done without delay. In a large number of cases, resection might be done to a very limited extent, especially when the neighbouring joint was not implicated in the disease of the bone. Up to 1879 he had successfully treated in this way five cases of this kind, but afterwards he had twenty-one cases. Of these, the elbow-joint was affected in eleven cases; the hip in four;

the tarsus in six; and the knee in five. Ten recovered with useful limbs; in twelve, small fistulæ still remained; one died of erysipelas; and the result in one case was not known. Such diseases of bone usually revealed themselves by abscesses affecting the epiphysis, and by little pits on the surface of the bone, which denoted the commencement of fistulous tracks. An accidental opening of the joint in operating was harmless, under antiseptic protection. Cases might occur, though rarely, in which the morbid deposit in the bone could only be reached through the joint.—*London Med. Record*, June 15, 1881.

Ozæna from Retained Secretion.

Dr. KENDAL FRANKS, in a paper read before the Dublin Biological Club, and published in the *Dublin Journal of Medical Sciences* for June, 1881, reports several cases of this not rare form of ozæna. He makes the following remarks upon this important subject:—

In treating of the subject of ozæna in general we must distinguish between two classes of morbid conditions in which fetid nasal breath is a prominent symptom. I exclude at once all cases in which the fetor is due to diseases in the deeper structures of the nasal cavity, as ulceration, caries of the bones, and abnormal growths, or when foreign bodies are the immediate cause.

But, independently of these, we find two distinct classes—one in which the ozæna is due to some lesion of the mucous membrane, most frequently the result of a dyscrasia; the second class comprising those cases in which there is no such lesion to which to attribute the disease, or in which an altered state of the mucous membrane is the result of the ozæna, and not its cause. This form has till the last few years been apparently quite overlooked, and it at present forms the subject of an interesting and animated controversy with our Continental brethren. It is to this latter form that I desire to call your special attention.

In all the standard works in which the subject of ozæna is discussed we find no allusion to this form of the disease. In Ziemssen's Cyclopædia, ozæna, the "Stinknase" of the Germans, the "punaisie" of the French, from its fancied resemblance to the smell of crushed bugs, is classed under the same heading as chronic rhinitis, and it has origin accordingly in a dyscrasia. "Acute rhinitis," Fraenkel tells us, "may pass into the subacute or chronic forms, and yet in the vast majority of cases this *only takes place in persons suffering under a dyscrasia.* Scrofula and syphilis are particularly liable to induce this transition. . . . We can distinguish two forms of chronic catarrh in the nose—the hyperplastic and the atrophic forms. They often coexist, but in most cases the atrophic form seems to be the result of the hyperplastic; at least it is most commonly found in old cases, and after the prolonged continuance of the hyperplastic." This is the order of events which we find in the pharynx: The three stages of chronic follicular pharyngitis are repeated in the nasal cavities, beginning as a chronic catarrhal pharyngitis, going on to hypertrophy of the follicles and mucous membrane, and finally, as the follicles wear out, the retrograde process taking place, and atrophic pharyngitis or pharyngitis sicca being the result. In the nose we have the same sequence—a chronic rhinitis is established. This is the result of an acute attack occurring in persons presenting other symptoms of dyscrasia; or "in persons having no dyscrasia, an acute rhinitis under bad care, continuance of the irritant, and under injurious influences, may relapse and finally terminate in the chronic form." This chronic form is at first of the hypertrophic kind, the mucous membrane being thickened and red, the secretion being of a muco-purulent character, and abundant in quantity. Morgagni relates a case in which it amounted to an ounce per hour. Should the mucous membrane be sufficiently tumefied to

cause obstruction of the nose, the secretions are retained and by degrees decompose, their composition giving rise to the fetor of ozæna. This, however, is not a very frequent occurrence during this stage of the disease. It is in the later stage, when the hyperplasia gives place to atrophy, that this symptom declares itself with all its unpleasant consequences. To this latter stage Gottstein applies the term, "chronic atrophic rhinitis." Robinson, in his recent work on "Nasal Catarrh," calls it "the dry form of chronic coryza." It seems to be brought about in the following way: During the hypertrophic stage there is deposited in the deep layer of the mucous membrane new formations of connective tissue and hyperplasia of the normal elements found there. This new tissue so presses upon the glands and follicles that their function is almost, if not entirely destroyed, and they consequently atrophy, or as the inflammatory products become organized and contract, they so constrict the glands that atrophy is the result. In proportion to the activity or intensity of these processes is the rapidity with which these changes occur; and hence, though we generally find the atrophic stage coming on at a late period after the hypertrophic stage has existed for years, still we need not be surprised if we find them coming on at a comparatively early epoch, so that the early stage of enlargement of the glands, thickening of the mucous membrane, and abundant secretion, may almost be overlooked. The appearance of the nasal passages and of the naso-pharyngeal space is very characteristic. The first thing we observe is an abnormal dryness of the mucous membrane in these regions. It has a glazed, parchment-like appearance, and is covered with inspissated mucus. This is very thick, and has a tendency to form crusts: "These," says Fraenkel,[1] "become firmly attached to the subjacent surface, perhaps owing to the large amount of albumen they contain, and by reason of their wealth in morphological elements (numerous epithelial cells) and their dearth of fluid constituents, are easily dried by the air passing over them." The tenacity with which these crusts cling to the mucous membrane beneath is exhibited when trying to remove them—sometimes they resist even a stream of water directed against them; and this tenacity is characteristic also, though in a less degree, of the dry pellicle of mucus which has not gone so far as to form crusts. The amount of secretion is very great, and is poured out as thick viscid mucus. It, however, rapidly dries, and if retained, as it will be unless proper means be used to get rid of it, it decomposes and gives rise to the characteristic stench. Fraenkel attributes the retention and drying of the secretion to the abundance of cells, the paucity of water, and its stickiness, but considers that defective cleaning of the nose aids in accomplishing the result: "This may be owing to habitual failure to blow one's nose, to feebleness of the expiratory current of air at the point affected (stenosis), or to diminished reflex irritability and an absence of a disposition to sneeze." Cohen, in his lecture on Naso-pharyngeal Catarrh,[2] takes a more histological view of the case when he attributes these conditions to a destruction of the epithelium. I need scarcely remind you that the epithelium lining the respiratory tract, with a few exceptions, is of the ciliated variety, and that the cilia have a continuous waving motion towards the exterior. In the nasal passages these cilia are continually brushing away excess of mucus. The diseased condition of the mucous membrane in chronic rhinitis causes destruction of numbers of the ciliated epithelia, and these are not reproduced. Hence this *potent* cause, according to Cohen, is absent, and retention is the result.

On removing the dried mucus and crusts from the surface, the mucous membrane has a remarkable appearance—it is reddened, the result of the cleansing

[1] Ziemssen's Cyclopædia, vol. iv. p. 138.
[2] Medical News and Library, October, 1879.

process, and looks dry and raw. Looking up into the naso-pharynx, by means of the rhinoscope, the same condition is seen, and tumefied masses of glands and follicles are visible on the vault and sides. The posterior portions of the turbinated bones present the same dry crusts and pledgets of mucus, and sometimes an entire turbinated bone is covered over as if with a false membrane. Anteriorly the same appearance is seen. The turbinated bones are distinct and normal in size, the mucous membrane covering them thin and atrophied, the secretion dry and encrusted. The symptoms which this condition give rise to are similar to those observed in the next class of ozænæ, to which I will now call your attention.

In this class of ozænæ no lesion is found, no disease of the mucous membrane, to which this disagreeable condition can be assigned; cases in which there is no previous history of a catarrh, or of a period at which there was an abundant odourless discharge. To account for such cases, to determine the true cause for a most pungent symptom, where to all appearance no disease exists, has been the endeavour of several astute observers in Germany. Several, among whom I may mention Gottstein, have attempted to class these cases under the third or atrophic form of chronic catarrh; but this is eminently unsatisfactory, as there has never been a second or third stage—and for other reasons to which I shall have occasion to refer again, I pass by this opinion as untenable. There still remain two views, which have been put prominentlyforward by their exponents. The first we shall consider is that propounded by Michel.[1] Recognizing the fact that the mucous membrane of the nose and pharynx is more or less healthy, and that its condition is quite insufficient to account for the ozæna, he lays emphasis on the exceeding abundance of the discharges. The mucous membrane of the nasal passages he considers is incapable of secreting so abundantly; for, if altered, it is on the side of atrophy. Whence then does the discharge come? Evidently not from the nose, but from the accessory cavities. The only cavities which could be the cause of it are the sphenoidal and ethmoidal sinuses, since anatomical considerations preclude the other sinuses from being the chief factors. Thus the opening of the antrum into the middle meatus of the nose is situated in the upper part of the internal wall, so that any flow of mucus from it could only be by overflow, and there are no evidences that the antrum is full of fluid. The frontal sinuses could not discharge fluid on to the upper surface of the middle turbinated bone, where it is seen to exist, as their openings into the nose are situated below the anterior extremity of this bone. Hence he concludes that a chronic catarrh exists in the sphenoidal and ethmoidal sinuses, which by retaining the secretions allows them to decompose, and by then discharging them over every portion of the nasal cavity gives rise to ozæna.

Now this theory, which is very plausible, is not sustained by facts. In the first instance, the grounds on which it is based are hypothetical, for the author has failed to demonstrate that any catarrh of these sinuses does actually exist; whilst, on the other hand, in a well-marked case of the disease, Hartmann, who made a *post-mortem* examination, could detect no abnormal condition of these cavities.

The second view enunciated is by Zaufal,[2] and the cases which I shall lay before you seem to me to support this view. He states the case thus: This class of ozæna, in which no lesion is found, affects children, and especially girls arriving at the age of puberty. The parents usually state that the fetor began to show itself within the last few months. The child finds great difficulty in blowing its

[1] Maladies du Nez et du Pharynx Nasal. Berlin, 1876. Traduction Franç. Par A. Capart. Paris, 1879.

[2] Aerztliches Correspondenzblatt aus Böhmen, No. 23, 1874.

nose, and the particles emitted are composed of horribly fetid, greenish crusts. The young patient is pale and dispirited, complaining sometimes of cephalalgia. The scrofulous diathesis is not specially marked; the nose is flattened, the septum is deflected to one side, so as to compress the lachrymal canal and cause epiphora. The alæ nasi are enlarged, but the nasal fossæ specially have a remarkable aspect to those who are well acquainted with their usual appearance. Instead of the normal narrowness of the passages between the septum nasi and the middle and inferior turbinated bones, a true cavern is seen to exist, due to the almost complete absence of these two turbinated bones, especially of the inferior, which are reduced to mere ridges, thus exposing to view the trumpet-shaped opening of the Eustachian tube, all the movements of which during phonation and deglutition are clearly seen. The whole septum and back of the pharynx are well exposed. Abundant semi-inspissated or dried crusts cover over the various parts, and if they be removed by irrigation the mucous membrane beneath is found to be reddened, but without any trace of ulceration. At the same time it seems to be atrophied. Over the inferior turbinated bone the erectile structure has disappeared, and a probe comes into immediate contact with the turbinated bone. This characteristic conformation may exist only on one side, or it may be hereditary, the mother who brings the child having a nose formed absolutely in the same way.[1]

Michel, who has seen this condition and recognized it, in holding to his own view, does not consider the malformation sufficient explanation of the disease; whilst Gottstein considers that the small size of the bones is part of the general atrophic process which goes on during the third stage of the catarrh. But then Michel's theory does not explain why the ozæna should be hereditary, why it appears always at puberty, or why it may sometimes be unilateral; and Gottstein does not state why in some cases of atrophic catarrh the turbinated bones do *not* share in the process.

On the other hand, Zaufal maintains that this excessive arrest of development explains these points, as well as accounting for the occurrence of ozæna. The ozæna is simply the result of the size of the nasal fossæ. The mucous secretions are no longer driven forwards little by little, as takes place in the normal condition when the expired air plays on the turbinated bones. The air goes out more slowly; the mucus, no longer drawn with it, retains its position and decomposes. Moreover he points out that there is not an abnormal increase in the secretion, as stated by Michel, but that it is only apparent, and results from the fact that the patient cannot blow his nose. The disease does not make itself apparent in early life. The child is born with rudimentary turbinated bones. During the first few years, the nose being very small, the disease does not declare itself; but, as the child grows, the bones of the face gradually develop, the turbinated bones remain stationary, and at or about puberty ozæna appears.

The retention, drying, and decomposition of the secretion on the surface of the mucous membrane reacts in an injurious way on this membrane, with whose function it interferes, and thus causes it to undergo a process of atrophy more or less pronounced, so that this atrophy, instead of being the cause is in reality the consequence of the ozæna.

Blindness after Glaucoma.

KUBLI reports the following case of total blindness from glaucoma simplex, in which vision was restored. The patient, a man, aged 21, stated (*Klin. Monats. für Augen.*, Oct. 1880) that his sight had been steadily failing for twelve months,

[1] Hayem. Revue des Sciences Médicales, April 15, 1880.

with occasional appearance of a coloured ring around the light, and that two months ago he had suddenly become totally blind. No other symptoms were complained of. On admission, both eyes presented T + 2, glaucomatous cupping of the disks, total absence of perception of light, oval dilatation of the pupils. The pupils gave no reaction to light, but contracted with movements of convergence, and were contracted strongly by eserine. Iridectomy upwards was performed on each eye. Perception of light returned the following day. Vision ultimately reached 3-100; whether in both eyes, or in one only, is not stated. [The strong contraction of the pupils by eserine is worthy of note in connection with the exceptionally good result. There is no reason to believe that such contraction in a glaucomatous eye indicates that the angle of the anterior chamber, though compressed, has not reached the stage of solid adhesion.—*Rep.*] —*London Med. Record*, June 15, 1881.

Operation for Trichiasis.

FÆSCHE recommends (*Klin. Monats. für Augen.*, xix. Jahrg., January) the following modification of Arlt's operation for trichiasis. In the first act, the upper lid is split into an anterior and a posterior part, as in Arlt's operation. In the second act, the anterior part is pushed up on the posterior about 1-12th to 1-10th of an inch, and fixed with three sutures on the tarsal cartilage. The middle of the three sutures is applied transversely, and includes about 1-8th of an inch, the other two sutures are vertical. The raw surface thus left, in place of being allowed to heal by granulation, as in Arlt's method, is covered with a thin strip of epidermis taken from the upper arm with a razor. With proper care, this transplanted strip heals in its place in twenty-four hours. Immediately on the eye the author lays a protective disinfected with salicylic and boracic acid, then a fold of lint similarly disinfected, over this salicylic cotton-wool, and over all, carbolized gauze. The first dressing may remain on for forty-eight hours. The author has used this method in twelve cases, and is thoroughly satisfied with it.—*London Med. Record*, June 15, 1881.

Midwifery and Gynæcology.

The Broad Ligament and Pelvic Cellulitis.

The anatomical and pathological relations of the broad ligament to the cellular tissue of the pelvis have recently been occupying the attention of several distinguished French authorities. The internal female organs lie very conspicuously in the pelvic cavity, and are so characteristic in outline as to be fairly familiar to every student. Much has been written on the nature of pelvic cellulitis and pelvic peritonitis by the greatest authorities on the diseases of women, and it is easy to beg the question, and to accept the doctrine, not as yet entirely discarded, that injuries and diseases of the vagina and uterus may set up forms of inflammation in the cellular tissue of the broad ligament, ending in the formation of an abscess within that structure. The layers of this ligament, closely applied to each other between the Fallopian tube and the ovary, diverge widely below the ovary; and the anterior continues forwards, to form the serous investment of the bladder, the posterior passing backwards as the peritoneum forming Douglas's pouch. It is a common idea that the pelvic cellular tissue fills up the lower part of the broad ligament, where the peritoneal layers are diverging towards the bladder and rectum, and, passing upwards, forms a thin but distinct stratum of cellular tissue between the folds of the ligament as far as to its very uppermost limit

below, or rather around, the Fallopian tube. If this were really the case, the formation of abscess between the folds of the broad ligament would be of very frequent occurrence in pelvic cellulitis.

The presence of a distinct layer of cellular tissue in the interior of the ligament is, indeed, taught by the authors of one of the best and most widely studied French text-books; for in Cruveilhier and Sée's *Traité d'Anatomie*, it is written: "The broad ligaments are formed by two peritoneal folds and by an intermediate layer of cellular tissue, through which pass the numerous vessels and nerves supplying the uterus and ovary, as well as a quantity of muscular fibres derived from the uterus." Whatever may have been the views of past authorities on the anatomy of the ligament, they almost universally admitted the frequency of abscess within it. Dr. Matthews Duncan has shown, in his work *On Perimetritis and Parametritis*, that such a condition is "very far from being common." The error, he believes, arose from the frequency of the presence of pus within the veins and lymphatics of the ligament, in fatal cases of puerperal fever. At necropsies, these purulent collections were taken for circumscribed abscesses.

MM. A. Guérin and Lebec have recently made the broad ligament an object of special study, and the fruits of their researches will be found in the *Gazette Hebdomadaire de Médecine et de Chirurgie*, April 15th. They insist on the selection of perfectly normal adult bodies for the dissection of these parts, subjects not easy to obtain; for slight attacks of adhesive inflammation in the parts around the internal organs are very common. In detaching the peritoneum from the bony walls of the true pelvis, a layer of cellular tissue is pulled up with it; this layer, almost as aponeurotic as the pelvic fascia itself, they call the fascia propria. This layer seals up hermetically the outer extremity of the broad ligament, which lies entirely below the fimbriæ of the Fallopian tube and the ovary. Another layer of dense cellular tissue is given off horizontally from the fascia propria, and forms a complete floor to the broad ligament. Hence the interior of this ligament is bounded by the uterus internally, by the tube above, and by the fascia propria below and antero-externally. The amount of cellular tissue between the layers of the ligament is very small, and cannot be said to constitute a "layer." By carefully scratching a hole in the anterior layer of the ligament, a few grammes of coloured fluid or tallow may be injected between the layers, care being taken to stop the injection the moment that slight resistance is felt, otherwise the material will force itself under the peritoneum to an indefinite extent. When properly injected, the real cavity of the broad ligament, thus produced, measures a little over an inch vertically, somewhat less laterally, and not quite half an inch antero-posteriorly. Its boundaries will be those given above as bounding the broad ligament, except that it does not extend so high as the tube; and it will be found to be cut off from the walls and the lower part of the pelvic cavity by the fascia propria. Now, a parametric phlegmon, long held to be entirely situated between the layers of the ligament, forms a mass far bulkier than the cubic capacity of the cavity of the ligament.

It might, however, according to older theories, be believed that abscess could actually begin between the layers of the broad ligament, and readily extend lower and lower into the pelvic cellular tissue below. Guérin and Lebec deny that this extension of suppuration can occur, as the horizontal layer of their fascia propria seals up the lower limits of the ligament. The development and extension of inflammatory deposit in the pelvic cellular tissue must be traced to their sources; in short, to the lymphatic vessels.

The lymphatics of the vagina empty into larger vessels, which join each other at the level of the superior *cul-de-sac*—the level, in fact, of the body and the cervix of the uterus. Under the cervical mucous membrane is a very dense lym-

phatic plexus, which communicates with the large vessels of the upper part of the vagina. From these united vessels, one or two large trunks pass outwards towards the pelvic walls, running along the base of the broad ligament, but entirely below it, and therefore separated from its cavity by the impermeable flooring of fascia propria. The trunk-lymphatics ultimately empty themselves either into one single gland, or else, more commonly, into a series of glands situated on the inner aspect of the ischium, close to the obturator foramen. From thence, lymphatic vessels ascend behind the pubes, and directly communicate, at the level of Poupart's ligament, with vessels from the thigh. They then ascend, in front of the peritoneum and behind the rectus and its sheath, and follow the epigastric vessels upwards. The lymphatics of the body of the uterus, on the other hand, actually pass between the layers of the broad ligament on their way to the lumbar glands, but they pass in its very uppermost part, quite above its cavity.

The course of the lymphatic vessels from the vagina and cervix explains certain symptoms frequent in pelvic inflammation, symptoms which cannot be logically referred to abscess in the broad ligament, but which represent what M. Guérin terms *adéno-phlegmon juxta-pubien*. Postpubic lymphangitis will sound a trifle less objectionable to British ears; but rather let us banish such terms, and say that, according to M. Guérin, pelvic cellulitis (evidently the same thing) begins as lymphangitis, produced by any severe irritation to the vagina or cervix; then the large lymphatic trunks below the broad ligament become involved; the gland or glands close to the obturator foramen enlarge, and may be detected on digital examination by the vagina; and the inflammation may extend to behind Poupart's ligament, or even form a hard mass palpable through the rectus, and following, from the groin upwards, the course of the epigastric arteries, as in a case described by M. Rigal. When the morbid process extends, the tissue round the lymphatics may become indefinitely involved, and abscess form at any point along the track above described. This condition represents the "parametritis anterior" of some authors. Hence the ill-defined extensive hardenings and the scattered collections of pus frequent in pelvic cellulitis. In short, says M. Lebec, the anatomy of the lymphatics of this part thoroughly explains the clinical symptoms of pelvic cellulitis. The structure of the broad ligament proves how rarely this affection can start from that appendage of the uterus; so that we may say, with M. A. Guérin, that the clinical symptoms of abscess situated actually and primarily between the layers of the broad ligament have yet to be discovered. —*Brit. Med. Journ.*, June 4, 1881.

Obstetrical Auscultation.

In a clinical lecture (reported in the *Revue Médicale*, No. 7) Prof. DEPAUL, after adverting to the history and progress of obstetrical auscultation, to which no one has contributed more than himself, proceeded to explain to his class how best to perform it. The woman should be laid on a bed on her back—for although she can be auscultated while standing, this is very inconvenient, and may give rise to serious mistakes. The abdomen should be exposed free from all garments, especially among common women, whose coarse clothing might give rise to difficulty in the perception of sounds. In private practice it may be possible to make an examination over a chemise of fine linen. The physician must place himself on her left and right side alternately, so as to make the examination of both sides, the most complete silence being observed. The auscultation must be made by means of the stethoscope; and after having tried the various forms of this instrument, Prof. Depaul has finally adopted one of medium length, having its auricular surface slightly excavated and the edges of the opposite aperture sufficiently thick to prevent disagreeable or painful sensations being

caused. The wall of the abdomen and that of the uterus must be somewhat depressed, but only moderately so, as any strong pressure would modify the sounds to be perceived, and especially the *souffle*. Some women refuse to allow of auscultation, but a little persuasion and explanation of the objects in view usually overcome their objections. There are others, again, who have the abdominal surface in a state of hyperæsthesia, the slightest touch, according to their account, causing pain. Moreover, in morbid conditions of the respiratory organs, the various pathological sounds produced may render the uterine auscultation difficult.

It is towards the third month and a half, or the fourth month, that auscultation is of service; and the sounds produced are of two kinds, those proceeding from the pregnancy itself, and those which are independent of it. Of the first, there are the uterine *bruit de souffle* and the double sound resulting from the contractions of the fœtal heart, the fœtal *souffle* dependent upon the circulation of the fœtus, and the uterine *souffle* dependent upon the maternal circulation. Finally, there are sounds due to the active movements of the fœtus, as the *bruits de choc*, which may be both perceived by the hand and heard by the ear. We may also perceive by palpation, as well as by the ear, a friction sound (*bruit de frottement*). As to the sounds independent of pregnancy which are heard in women with child, it is of importance not to confound them. They may arise from the constriction of the muscles of the abdomen, or from the vesicular expansion of the lungs, which in some women extend from above downwards. So also the sounds produced by the beating of the heart of the mother may be transmitted to the cavity of the abdomen, and these are to be distinguished from those of the fœtus by their isochronism with the pulse. Finally, there are the pulsations of the aorta, and the sounds due to the presence of gas in the digestive canal, especially in nervous and impressionable women.

The maternal *souffle* has been designated by various names, but Prof. Depaul prefers that of "uterine *souffle*," given it by Paul Dubois; and although it is not the most important of the sounds inherent to pregnancy, it is very desirable that it should be known. It is a *souffle* without pulsations isochronous with the maternal pulse. It is more or less strong and intermittent in the great majority of cases, having a certain interval between two successive *souffles*. It is sometimes musical or sibilant, analogous to the sound produced by a large bass-string —at least, these are the typical sounds, of which, however, numerous shades exist, and which may be modified at intervals of a few instants in the same subject. There is no part of the uterus at which this may not be heard, but still there are generally three points of predilection—at the right and the left (sometimes both sides in the same woman), and at the fundus. This uterine maternal *souffle* may sometimes be absent on the first examination, for it is capricious, and not being constant, like the beatings of the heart, it may disappear and reappear occasionally. It is heard from the fourth or fifth month until the end of pregnancy. Nearly everybody is agreed in admitting that this sound is produced within the interior of the walls of the uterus, and that its mobility is due to the movements of the child, which compress this or that artery according to the position it occupies at the moment.—*Med. Times and Gazette*, July 23, 1881.

—

Pilocarpin in the Treatment of Puerperal Convulsions.

In the *British Medical Journal* for April 2, 1881, Dr. A. HAMILTON reports the following interesting case.

M. J. E., aged 22, domestic servant, a primipara, and previously healthy, was suddenly seized with convulsions. When seen by me, she was in a violent gen-

eral convulsion, which had continued for two hours. On examination, I found her to be in the sixth or seventh month of pregnancy, the os rigid and undilatable, and the urine loaded with albumen. The convulsions continuing, and it being impossible to give anything by the mouth, I injected hypodermically, six hours from her seizure, fifteen minims of a two-per-cent. solution of pilocarpin. This was followed in about two minutes by very profuse salivation and perspiration; the convulsions ceased, and strong uterine contractions soon became evident. After an interval of an hour, she had seven fits in quick succession. Mr. Taylor then saw the patient with me; and, with his concurrence, I gave, two hours after the first, a second injection of pilocarpin. The salivation following this was so copious as to threaten suffocation, and, although the convulsions became weaker and less frequent, the breathing was so much embarrassed as to make the patient's recovery almost hopeless. Pains, however, became stronger and more frequent; the fœtus being expelled ten hours after the last injection. The woman remained unconscious for two days, and then recovered rapidly.

In puerperal convulsions, I have found the best treatment to be dilatation of the os uteri, with or without chloroform, and speedy delivery; but in the foregoing case, one of the worst I have ever seen, the convulsions seemed to be so much controlled by the pilocarpin, that I shall certainly use it again in such cases. I may also say that I have used jaborandi with very good results in cases of Bright's disease and spasmodic asthma.

Medical Jurisprudence and Toxicology.

Cadaveric Alkaloids.

The very serious question, from the medico-legal point of view, of the spontaneous development of cadaveric alkaloids and their toxic power, was first raised by M. Selmi of Bologna. After many vicissitudes of alternate favour and discredit, this subject has been revived in France by the researches of MM. Brouardel and Boutmy, in Germany by those of M. Husemann, and in Italy by the *résumé* of all the information on the subject recently published by the original discoverer, M. Selmi. These researches are succinctly summarized in the *Gazette Hebdomadaire*, and their results given in a concise form as follows: Last year, at the Congress of Rheims, M. Boutmy read, in his own and M. Brouardel's name, a paper which excited much attention, and in which the joint authors, after having shown that the existence of cadaveric alkalies has been erroneously contested, insisted on the toxic properties of ptomaïnes, pointing out that the activity of some of these substances is in no degree inferior to that of the strongest poisons. They demonstrated that there are many distinct ptomaïnes, each showing special chemical and physiological characteristics; and noted the following fact, of which the importance is clear: that one of these ptomaïnes, extracted from a corpse which had been eighteen months in the Seine, had all the properties of veratrine. Since the time they read this paper, its authors have followed up their researches by devoting themselves to the determination of the differences, either chemical or toxicological, which might prevent the confusion between the poisons formed by putrefaction and the venomous substances absorbed during life.

One of the first results of their labours is a paper presented to the Académie de Médecine on May 10th, in which they point out the property of the ptomaïnes to bring back the ferricyanide of potassium to the condition of ferrocyanide, which is capable of forming Prussian blue with, for instance, the chlorides of iron. The

same reagents, however, in presence of pure alkaloids or extracts from a corpse after poisoning, do not undergo any change. These researches are being continued, and doubtless new facts will corroborate the facts already obtained. MM. Bergeron and l'Hôte, who have been studying the toxic effects of amylic alcohol, point out that, this alcohol being employed in the extraction of ptomaïnes, it becomes a question whether the toxic action of these alkaloids may not be partly due to amylic alcohol, frequently mixed with butylic alcohol, used to extract them. MM. Brouardel and Boutmy, however, state that they have not fallen into the probable cause of error here pointed out. Husemann (*Les Ptomaïnes et leur Signification en Chimie Légale et en Toxicologie*) has taken up the study of ptomaïnes from another point of view. He has felt doubtful whether these substances may not account for the poisonings by alimentary substances and putrid infections. The researches of Hoppe-Seyler, Schmidt, Schmideberg, and Panum have shown, in alimentary substances in a state of putrefaction, the presence of alkaloids analogous to ptomaïnes (Schmidt's and Schmiedeberg's sepsine and Panum's putrid poison). Husemann concludes that, as a matter of fact, the majority of the accidents observed in persons who had partaken of food in a state of commencing putrefaction are to be imputed to these alkaloids, which are of similar constitution to ptomaïnes (Schmidt's *Jahrbücher*, 1880). M. Selmi, in his recent work on the subject (*Les Ptomaïnes, les Alcaloïdes Cadaveriques, et les Produits Analogues des certaines Maladies dans leurs Rapports avec la Médecine Légale*), has collected his former researches on ptomaïnes and the method of distinguishing them from the true alkaloids, and has added a paper on the technical method of extracting ptomaïnes, and on the chemical differences which differentiate them from colouring and resinous matters. An interesting paper relating to the toxic effects produced by the extractive substances obtained from the urine of certain patients will also be found in this volume.—*British Med. Journal*, July 30, 1881.

The Influence of Ammonia in Chloroform-Poisoning.

Dr. SIDNEY RINGER, in a paper published in the *Practitioner*, June, 1881, p. 437, shows, by experiments, the rapid influence ammonia exerted in a frog's heart, whose action had been arrested by an overdose of chloroform. The chloroform evidently paralyzes the heart's muscular substance, affecting the ganglionless and nerveless portion of the ventricle exactly in the same way as any other part of it. [In the *Medical Times and Gazette*, May, 1871, p. 616, Dr. Neild reports a case of apparent death from chloroform inhalation, which recovered from the alarming state of syncope after four half-drachm injections of liquor ammoniæ into the median cephalic vein.—*Rep.*]—*London Med. Record*, July 15, 1881.

—

Poisoning by Potassium Bichromate.

Dr. WM. A. M'LACHLAN reports the following case of this rare form of poisoning:—

James W., aged 60, of spare build and nervous temperament, followed the occupation of a goods clerk. He had been complaining for some time with a dull pain in the hypochondriac regions, and had been doctoring himself with a variety of medicines. One of his fellow-workmen suggested to him a trial of bichromate of potash and rhubarb. Acting on his advice he procured these at a registered druggist's. While returning home with his medicines, he met in with a friend, and adjourned to his neighbour's house. Here he unfolded the packet of bichromate of potash, and after explaining its supposed utility, took fully three drachms

of it. He dissolved it in cold water, then drank the solution. This was shortly after 3 P. M., on 9th March, 1880. He had not taken it more than one-quarter of an hour, when the symptoms of an irritant poison began to manifest themselves in the form of excessive vomiting and purging, accompanied with violent abdominal cramps. At this time, the woman of the house he had entered gave him an emetic of common salt and plenty of water to drink. At 5 P. M., when I was called, I found him reclining on a chair moaning and complaining of cramps in the abdomen and lower limbs. The surface of his body was cold. His hands and fingers were shrivelled, wrinkled, and dusky, much like those of a person in the advanced stage of cholera. His face and lips were very dusky. His beard was coloured chrome yellow. The mucous membrane of his mouth and throat was dark coloured. His breath was cold and his voice very feeble and tremulous. He was vomiting occasionally tough mucus mixed with blood. The mucus was very tenacious, and was with considerable difficulty removed from the mouth. His thirst was excessive. Pulse very weak and barely perceptible at the wrist. Respiration hurried. Urine suppressed. Mental faculties unimpaired.

Treatment.—He was covered up in bed, with hot blankets and hot jars placed in close proximity to him. Had olei ricini ℥ss at once. Then a dessertspoonful of brandy in hot water every quarter of an hour; also, water slightly acidulated with citric acid *ad lib.*, and milk gruel occasionally.

10 P. M. Much better. Slight perspiration on surface of body, trunk much warmer. Extremities still cold and cramped. Pulse 120 per minute, feeble, regular. Vomiting much less. Mucus much less tenacious. Thirst less; pain in abdomen less. Urine suppressed. Respiration still accelerated. Continue same diluents and give the brandy hourly.

March 10, 9 A. M. Has passed a restless night, slept very little. Vomiting almost gone. Cramps in the extremities still continue, the interval between them is much longer than last night, and the spasms themselves are not so prolonged, nor is the pain of them so severe. Thirst is not so excessive though still considerable. The heat of the body is much better. Pulse 120, better in volume, regular, though still feeble. Respiration more equable, though occasionally there is slight irregularity in the movements of the chest. Urine suppressed. Diminish the brandy to one teaspoonful every hour. Also to have liq. bismuth. ℥j every hour. Continue same diluents.

8 P. M. Patient is still better. Pulse 120 per minute, of better volume, regular. Respiration better. Cramps of extremities gone. There is still pain over the epigastric and umbilical regions. Vomiting almost gone. Urine suppressed. Continue treatment.

11*th*. 9 A. M. Patient still improving. Slept moderately well during the night. Vomiting entirely gone. Abdominal tenderness much less. Pulse 120 per minute, much stronger. Conjunctiva coloured a deep yellow. About one and a half ounces of urine have been passed since last visit—it is coloured chrome yellow. To have milk diet only. Also the following medicine: ℞. Pot. cit. gr. xxx; spt. æth. nitrosi, ℥ij. Sig.—To be taken every three hours.

12*th* Still better. Urine abundant—still coloured deeply yellow. Bowels normal. Can take liquid food, but finds his digestion very weak. Pulse 76 per minute, still feeble. Respiration normal.

It would thus seem that the specific remote effects of this salt not only manifest themselves by producing yellow discoloration of the conjunctiva, but also by causing enervation of the kidney, with suppression of urine, which in this case was well marked.—*Glasgow Med. Journ.*, July, 1881.

MEDICAL NEWS.

The International Medical Congress.

The recent meeting of the International Medical Congress in London, the seventh of the kind, from the reports which have reached us, appears to have been an unqualified success; the weather was favourable, the arrangements carefully made, the attendance very large (between three and four thousand), the addresses excellent, and the proceedings in the Sections distinguished by papers of unusual interest and importance. Upon another page will be found a brief but graphic account, from the pen of the Editor of this Journal, of the proceedings, and of the entertainments given to its members, from which it appears that the occasion was diligently and enjoyably improved. By a judicious arrangement, the committee obtained in advance abstracts of papers to be read; and these, in English, in French, and in German, were published in a portly volume of over 700 pages, and distributed on the first day of the session. It not only formed a valuable guide to the discussions, but also affords a very fair *résumé* of the intended proceedings. The meetings commenced on Aug. 2d, and continued with daily sessions until Aug. 9th, in accordance with the following programme:—

Tuesday, Aug. 2. 10 A. M. to 6 P. M.: Registration of Members. 3 to 6 P. M.: Informal reception at the College of Physicians. 9.30 P. M.: Conversazione given by President of Odontological Society to the members of Odontological Section.

Wednesday, Aug. 3. 11 A. M.: General Meeting at St. James's Hall; Chairman Sir William Jenner. The Prince of Wales will declare the Congress open. Inaugural Address by Sir James Paget. 3 P. M.: Meeting of the Sections. 4 to 7 P. M.: Musical Promenade in Royal Botanic Society's Gardens. 4.30 P. M.: General Meeting. Address by Professor Virchow. 9.30 P. M.: Conversazione at South Kensington Museum.

Thursday, Aug. 4. 10 A. M. to 1 P. M.: Meetings of Sections. 1.30 P. M.: Visits to Hospitals. Demonstration of Natural History Collection at South Kensington by Professor Owen. 2 P. M.: Meetings of Sections. 4 P. M.: General Meeting. Reading of the late Professor Raynaud's Address by his friend Dr. Féréol. 6.30 P. M.: Banquet given by the Lord Mayor at the Mansion House.

Friday, Aug 5. 10 A. M. to 1 P. M.: Meeting of Sections. 12.45 P. M.: Visit to Mr. Penn's Works at Greenwich. 1.30 P. M.: Visits to Hospitals. Demonstration of Natural History Collection at South Kensington by Professor Owen. 2 P. M.: Meetings of Sections. 4 P. M.: General Meeting. Address by Dr. Billings. 8 P. M.: Conversazione at the Guildhall. Soirée at the Royal College of Surgeons, free to members of the Congress.

Saturday, Aug. 6. 10 A. M. to 1 P. M.: Meetings of Sections. 12.15 P. M.: Excursion to Croydon Sewage Farm. 1.45 P. M.: Excursion to Folkestone—Unveiling of Harvey Memorial Statue. 2 P. M.: Excursion to Hampton Court, and Garden Party at Normansfield, given by Dr. Langdon Down. 4 to 7 P. M.: Reception at Kew Gardens by Sir J. D. Hooker. Garden Party at Hampstead,

given by Mr. and Mrs. Spencer Wells. Garden Party at Wimbledon, given by Mr. and Mrs. Saunders. 6.30 P. M.: Dinner at Richmond, given by the United Hospitals Club. Reception by the Foreign Secretary to the Foreign Members of the Congress.

Sunday, Aug. 7. 10 A. M.: Full Choral Service and Sermon in Westminster Abbey. 3.15 P. M.: Full Choral Service, and Sermon by Canon Liddon, in St. Paul's Cathedral. 1.30 P. M.: Excursion to Boxhill. The Gardens of the Royal Botanic Society, Zoological Society, and at Kew and Hampton Court, will be open to Members of the Congress.

Monday, Aug. 8. 10 A. M. to 1 P. M.: Meetings of the Sections. 11 A. M.: Visit to the Docks. 2 P. M.: Meetings of Sections. 4 P. M.: General Meeting. Address by Prof. Volkmann; Garden Party by Lady Burdett-Coutts Bartlett. 6.30 P. M.: Dinner given by the Masters and Wardens of the Society of Apothecaries. 9.30 P. M.: Conversazione given by the Royal College of Surgeons.

Tuesday, Aug. 9. 10 A. M. to 1 P. M.: Meetings of Sections. 2 P. M.: General Meeting. Address by Professor Huxley. 4 P. M.: Visit to the Crystal Palace; Informal Dinner, and Display of Fountains and Fireworks, etc.

In this connection, and as an instance of medical journalistic enterprise, we note that the *Boston Medical and Surgical Journal* for August 18th, but issued two days in advance of date, contains in full the opening address by the President, Mr. James Paget, the Introductory Remarks delivered upon the opening of the Section in Pathology by Samuel Wilks; on Surgery by John Eric Erichsen; in Obstetrics by Alfred McClintock; and in Anatomy by Prof. W. H. Flower; and an interesting letter from London on the subject of the meeting; altogether forming a most interesting, timely, and valuable issue of this representative Journal.

The Sanitary Condition of Summer Resorts.

The Isle of Wight, sometime known as the Garden of England, but according to the *Practitioner* now deserving of a much less complimentary and euphemistic title, as a summer resort is under a cloud. It appears that the Local Government Board, having had its attention directed to the matter, resolved to subject the sanitary administration of the island to investigation, and delegated the task of inquiry to an energetic health officer, Dr. Ballard. From the official report of this observer, just made public, it appears that this particular garden-spot is one to be carefully shunned by all summer tourists who have the slightest regard for their health. The *Practitioner*, in a very forcible editorial upon this subject, based upon Dr. Ballard's report, says that it appears that "the sanitary affairs of the island are in the utmost state of confusion, and that the authorities, who should be responsible for keeping the island free from those accidental sources of impurity which necessarily accompany houses and communities, have done nothing of the sort, or done so only in the incompletest fashion; and that the island has become defaced by conditions detrimental in the highest degree to its own inhabitants and peculiarly detrimental to the health and well-being of visitors."

One of the earliest and most important results of such neglect of proper sanitary regulation, of which Wight is by no means an isolated example, is the pollution of the water supply, and this is the very subject which must be kept constantly and prominently before the authorities of small out-of-the-way communities periodically subjected to overcrowding by summer visitors. The bill of indictment against Wight is clear, and carries conviction with it; the report of Dr. Ballard not only should be read by sanitarians and physicians, but it has its lesson as well for every summer tourist. That the Isle of Wight is peculiar among summer resorts in England or the Continent in its defective sanitation, no one will assert; they may "do these things better in France," but we have serious doubts whether there are many popular places of resort where in the details of scavengering, practice will at all approach theory, even in the native home of sanitary science. The earnest recommendation made only a short time ago, by the editor of the *British Medical Journal*, to tourists to carry their water supply with them, or at least to drink nothing while travelling on the continent except Apollinaris, is still fresh in our minds, and emphasizes the point that we wish to insist upon.

If we inquire further and ask the sanitary status of similar places upon the American continent, we find that the mushroom growth of many of our summer resorts has, almost without exception, effectually militated against anything like intelligent hygienic administration. The summer visitors take the ordinary hygienic conditions for granted on account of the great natural advantages principally in the way of ventilation, which usually are found at localities selected for summer habitation; if they are taken sick the water disagrees with them, and they go away, blaming their weakness rather than the water; but others come to fill their places probably to go through a like experience. In an excellent report on the Drainage of Summer Hotels and Boarding Houses,[1] Mr. Ernest W. Bowditch, an engineer of Boston, gives the results of investigations into the sanitary condition of one hundred and fifty of these "health resorts" (*lucus a non lucendo*), which were found to be almost without exception unsatisfactory and liable to become at any time breeding places for epidemics of typhoid fever, diphtheria, and other infectious diseases. These New England hotels and boarding houses are the prototypes of others all over the country; no doubt in many places the conditions are even worse, for these examples, it should not be forgotten, are taken from a section of the country noted for its thrift and cleanness. At Newport some years ago, matters became so serious that the inhabitants were forced to adopt prompt measures for self-protection, which fortunately resulted in the establishment of a very efficient system of sanitary inspection and control

[1] First Annual Report of the State Board of Health, Lunacy, and Charity of Massachusetts, 1879. Supplement containing report and papers on Public Health, Boston, 1880.

which now serves as a model for other places of resort.[1] Some portions of Long Island are notoriously unhealthy. New Jersey has a large number of watering places upon its coast, which are visited by enormous numbers of people every year. Atlantic City and Cape May in particular are poorly drained, and still retain the primitive method of water supply, by rain water collected from the roof, left as regards cleanliness to individual enterprise without any attempt at the much-needed systematic filtration. There are also some surface-wells which are occasionally resorted to by the poorer classes. At the former place during the past summer some activity has been manifested, and a system of sanitary inspection and scavengering projected, which we hope will be freely matured and actively in operation before next season. Fair Point, Chautauqua, was recently in such bad sanitary condition as to attract public attention, on account of the presence of a large number of persons dwelling in tents and temporary structures. Under the efficient direction of the very intelligent administration, acting under the suggestion and advice of Prof. Lattimore, we believe this has been largely corrected, but there is yet much to be done to make it what its natural advantages entitle it to be. We need not pursue this subject further by multiplying illustrations, but would direct professional and public attention to the drainage, sewage, and water supply of our places of summer resort as a subject worthy of earnest and careful consideration. In 1875, Dr. Henry Hartshorne read before the American Public Health Association a brief paper entitled a "Preliminary Report on the Sanitary Conditions of American Watering Places,"[2] and urged that "the same principles of sanitary science and practice, essentially, are capable of illustration in camps and in places of summer resort" owing to the great periodical increase in the population at places where everything is temporary, as it were, and migratory, not permanent. We mention this matter particularly at the present time, in order that the intelligent and enterprising proprietors of places of summer resort may see the necessity of satisfying popular opinion in this matter of sanitary reform, and in putting their houses in order for next season they may adopt the latest methods of scavengering and the greatest precautions to insure uncontaminated water supply. We hope that they will not forget to invite a thorough examination by competent authorities of their premises, and in next season's circular, we shall be glad to see due prominence given to the announcement of the satisfactory sanitary condition of the house, with the examiner's certificate appended.

International Medical Congress, London, August 2—9, 1881.

(SPECIAL CORRESPONDENCE OF THE MEDICAL NEWS AND ABSTRACT.)

The seventh meeting of the International Medical Congress was formally opened in St. James's Hall, London, on Wednesday morning, August 3d, by his Royal Highness, the Prince of Wales, in the presence of about 2500 members. The Prince of Wales, on his arrival at the Hall, was received by Sir William Jenner, Sir William Gull, Sir James Paget, Mr. Mac Cormack, and the other members of the committee, and conducted to the platform; a little later the Crown Prince of Russia entered and took a seat on the left of the chairman. The large hall was crowded to its utmost capacity with eminent members of the profession, gathered together from every part of the world. Among the many distinguished persons present we recognized Virchow, Langenbeck, Charcot, Esmarch, Flint, Cardinal Manning, the Archbishop of York, the Bishop of London, Volkmann, Lister, Pasteur, Brown-Séquard, Fordyce Barker, Ranke, J. S. Billings, Kister, Snellen, Warren Bey, Sir William Gull, Spencer Wells, J. C. Hutchinson, Sapolini, and many others of equal prominence.

Sir William Jenner, K.C.B., President of the Royal College of Physicians, as chairman *ex-officio* of the general committee, called the Congress to order in a short address, in which he offered the acknowledgments of the profession to the Prince of Wales for the support which his Royal Highness had accorded to the Congress, and then referred to some of the objects which were to be attained by such an international gathering as was then assembled. He concluded by referring to the incessant and arduous labours which had devolved upon Mr. William Mac Cormac, the Hon. Secretary-General, in the devising and executing the preliminary arrangements for this Congress, and said that every member owed to Mr. Mac Cormac a deep debt of gratitude, which ought to be most heartily acknowledged.

Mr. William Mac Cormac, the Hon. Secretary-General, read the report of the Executive Committee, which contained a sketch of the origin of the meeting and of the steps that had been taken to insure to it a truly international character.

Sir J. Risdon Bennett, Chairman of the Executive Committee, then offered a resolution accepting the official list of officers nominated, and appointing Sir James Paget, Bart., President of the Congress, a number of honorary vice-presidents, including as American representatives Drs. Billings of Washington, Barker of New York, Bigelow of Boston, and Flint of New York, with Mr. William Mac Cormac, Hon. Secretary-General. Prof. Donders, as President of the preceding Congress, held at Amsterdam in 1879, seconded the motion in a short speech, in which he paid a just tribute of praise to the admirable arrangements which had been made for the meeting of the Congress. The resolution was carried by acclamation.

Sir William Jenner then presented to the Prince of Wales a medal struck in commemoration of the meeting of the Congress, and resigned the chair to Sir James Paget, the President-elect.

The Prince of Wales cordially greeted the President, and in a short and admirable address expressed his interest in the meeting, and the confident anticipation he felt in the great international benefits which must accrue from the conferences of men of science from all countries, and he formally declared the Congress open.

Sir James Paget then delivered his inaugural address, which was a thoughtful, philosophic, and eloquent statement of the true aims and objects of an international gathering such as this Congress was, and he concluded with the following

peroration, which, for nobility of thought and beauty of expression, fully justifies Sir James's high reputation as an orator:—

"And then, let us always remind ourselves of the nobility of our calling. I dare to claim for it, that among all the sciences, ours, in the pursuit and use of truth, offers the most complete and constant union of those three qualities which have the greatest charm for pure and active minds—novelty, utility, and charity. These three, which are sometimes in so lamentable disunion, as in the attractions of novelty without either utility or charity, are in our researches so combined that, unless by force or wilful wrong, they hardly can be put asunder. And each of them is admirable in its kind. For in every search for truth we can not only exercise curiosity, and have the delight—the really elemental happiness—of watching the unveiling of a mystery, but, on the way to truth, if we look well round us, we shall see that we are passing among wonders more than the eye or mind can fully apprehend. And as one of the perfections of nature is, that, in all her works, wonder is harmonized with utility, so is it with our science. In every truth attained there is utility either at hand or among the certainties of the future. And this utility is not selfish: it is not in any degree correlative with money-making; it may generally be estimated in the welfare of others better than in our own. Some of us may, indeed, make money and grow rich; but many of those that minister even to the follies and vices of mankind can make much more money than we. In all things costly and vainglorious they would far surpass us if we would compete with them. We had better not compete where wealth is the highest evidence of success; we can compete with the world in the nobler ambition of being counted among the learned and the good who strive to make the future better and happier than the past. And to this we shall attain if we will remind ourselves that, as in every pursuit of knowledge there is the charm of novelty, and in every attainment of truth utility, so in every use of it there may be charity. I do not mean only the charity which is in hospitals or in the service of the poor, great as is the privilege of our calling in that we may be its chief ministers; but that wider charity which is practised in a constant sympathy and gentleness, in patience and self-devotion. And it is surely fair to hold that, as in every search for knowledge we may strengthen our intellectual power, so in every practical employment of it we may, if we will, improve our moral nature; we may obey the whole law of Christian love, we may illustrate the highest induction of scientific philanthropy.

"Let us, then, resolve to devote ourselves to the promotion of the whole science, art, and charity of medicine. Let this resolve be to us a vow of brotherhood; and may God help us in our work."

The first general meeting then adjourned.

In the afternoon the Sections organized as follows: Section I. Anatomy, President, Prof. Flower. Section II. Physiology, President, Dr. Michael Foster, of Cambridge. Section III. Pathology and Morbid Anatomy, President, Dr. Samuel Wilks. Section IV. Medicine, President, Sir William Gull. Sub-section. Diseases of the Throat, Chairman, Dr. George Johnson. Section V. Surgery, President, Mr. John Eric Erichsen. Section VI. Obstetric Medicine and Surgery, President, Dr. McClintock, of Dublin. Section VII. Diseases of Children, President, Dr. Charles West. Section VIII. Mental Diseases, President, Dr. Lockhart Robinson. Section IX. Ophthalmology, President, Mr. Wm. Bowman. Section X. Diseases of the Ear, President, William B. Dalby, Esq. Section XI. Diseases of the Skin, President, Mr. Erasmus Wilson. Section XII. Diseases of the Teeth, President, Mr. Edwin Saunders. Section XIII. State Medicine, President, Mr. John Simon. Section XIV. Military Surgery and Medicine, President, Surgeon-General Professor Thomas Longmore. Section

XV. Materia Medica and Pharmacology, President, Prof. T. R. Fraser, of Edinburgh. In many of the Sections, the President delivered introductory addresses.

Subsequently, the Congress again met in general session to listen to an address on the Value of Pathological Experiment, by Professor Virchow.

In the evening a conversazione was given by the English members to the foreign members and ladies, at the South Kensington Museum, which was graced by the presence of their Royal Highness the Prince of Wales, the Crown Prince of Russia, and his eldest son Prince Henry. The beautiful courts and picture galleries of the Museum with their exquisite art treasures, combined with the brilliant illumination and the presence of the ladies, constituted a scene of rare beauty which will long be remembered by all who participated in it.

On Thursday, August 4th, the Congress met in Sections in the morning, and in the afternoon in general session, to listen to an address which was written for the occasion, and finished just before his untimely death, by the late Prof. Maurice Raynaud, of Paris, on "Le Scepticisme en Médecine, au temps passé et au temps présent," which was read by his friend Dr. Féréol. In the evening a banquet was given to a certain number of the members of the Congress by the Lord Mayor of London, at the Mansion House, at which were present the following representatives of the United States: Drs. Fordyce Baker, H. J. Bigelow, J. S. Billings, V. T. Bowditch, J. Solis Cohen, R. B. Cole, Austin Flint, Wm. Goodell, S. W. Gross, I. Minis Hays, A. Jacobi, M. A. Pallen, L. A. Sayre, and Wm. Thomson.

On Friday, August 5th, the sections again met in the morning, and in the afternoon the Congress met in general session to listen to an address on "Our Medical Literature," by Dr. J. S. Billings, of Washington, U. S. Dr. Billings considered his theme in reference to the growth of medical literature all over the world, and gave interesting statistics in regard to subjects written upon and the nationalities of authors. He then ably discussed the character and value of our literature and presented some valuable reflections on the making of it and on its utilization. Dr. Billings's address was often witty, and was very enthusiastically received, and the thanks of the Congress were tendered to him for it, by Sir James Paget, in most complimentary terms. In the evening a conversazione at the Guildhall was given to the members of the Congress and their ladies, by the Lord Mayor and corporation of the city of London.

On Saturday, August 6th, the Sections met in the morning, and in the afternoon garden parties were given by Sir Joseph Hooker, at Kew, by Mr. and Mrs. Spencer Wells at Golder's Hill, Hampstead, and by Mr. and Mrs. Saunders, at Fairlawn, Wimbledon. Excursions were also made to Folkestone, to witness the unveiling of the Harvey memorial statue; after which ceremony the Mayor and corporation of Folkestone entertained the visitors at a banquet in the Town Hall. At the invitation of Dr. Langdon Down, a number of the members visited Hampton Court and then proceeded by river to Hampton Wick, where they were entertained by Dr. Down at a garden party at his residence, Normansfield. Excursions were also made to the Croydon Sewage Farm, and to Hanwell Lunatic Asylum. In the evening a party of the members were entertained at dinner by the "United Hospitals Club," at the "Star and Garter," Richmond Hill, Mr. Thomas Bryant, of Guy's Hospital, in the chair. A reception at his residence, Carlton House, was tendered to the foreign members of the Congress, by His Excellency Earl Granville, K. G., Her Majesty's Minister for Foreign Affairs.

On Sunday, August 7th, a full choral service was held in Westminster Abbey, and the sermon was preached before the Congress by the Rev. Canon Barry; and in the afternoon at St. Paul's, with the sermon by the Rev. Canon Liddon.

Visits were also made by special parties to Bethlehem Convalescent Hospital, Witley, Surrey, to the Margate Hospital, where the new wing of the Royal Sea-bathing Infirmary for Scrofulous Disease was inspected, and afterwards the party were entertained at lunch by Mr. Erasmus Wilson. In the afternoon Sir Trevor Lawrence, Bart., M. P., entertained at luncheon a party at Burford Lodge, his residence in Surrey; and Mr. Lennox Browne entertained a number of the members of the Section of Diseases of the Throat at a very handsome dinner, at the "Star and Garter," Richmond Hill.

On Monday, August 8th, the morning was devoted to sectional meetings, and in the afternoon a general meeting was held, at which Prof. Volkmann, of Halle, delivered an address, entitled "Ueber Moderne Chirurgie," and Professor Pasteur communicated the results of his most recent investigations in vaccination in relation to the prevention of chicken cholera and splenic fever.

For the entertainment of the members a visit was made to the Docks under the guidance and hospitality of Sir George Chambers; Baroness Burdett-Coutts gave a beautiful garden party at her residence, Holly Lodge, Highgate; the Society of Apothecaries, a dinner at their hall in Blackfriars; and the Royal College of Surgeons, a conversazione; and at the same time an opportunity was afforded the members to view the Hunterian Museum.

On Tuesday, August 9th, the Sections met in the morning, and at 2 o'clock the sixth and concluding general meeting was held, at which Prof. Huxley delivered an address on "The Connection of the Biological Sciences with Medicine."

Mr. William Mac Cormac, the Hon. Secretary-General, then presented his report, in which he stated that 3210 persons had registered as members of the Congress; that 119 meetings of Sections had taken place, which had sat in the aggregate for 298 hours, or 12 days and nights. The attendance at the sectional meetings had been very large, and 464 written and 360 spoken communications had been made, and in their discussion great interest had been shown. Many additional hours had been spent in visiting hospitals and museums, where there had been demonstrations of various diseases. Some hours had also been spent in listening to the addresses in the general meetings and at the museum of the Congress, which had been crowded with visitors.

The President, Sir James Paget, announced that resolutions had been received from the Sections of Physiology and Ophthalmology, and that they had been very carefully considered in their respective Sections, and it was now judged best that there should now be no discussion on them; that they would be submitted to the meeting, which would adopt them or not, and if any member dissented from the action of the Congress he could have his vote recorded.

The resolution from the section of physiology was, "That this Congress records its conviction that experiments on living animals have proved of the utmost value to medicine in the past, and are indispensable for its future progress. That, accordingly, whilst strongly deprecating the infliction of unnecessary pain, it is our opinion that, alike in the interests of animals and of men, it is not desirable to restrict competent persons in their experiments." The resolution was received with great applause, and was carried without a single dissentient voice.

The president then explained that the Ophthalmological Section had prepared a series of tests which it recommended for persons working signals on land and sea, and that its views were about to be drawn up in due form by a committee. In the mean while the Section recommended that its action should be adopted as the action of the Congress in order that the recommendations might be forwarded by the Secretary-General to the President of the Board of Trade, the First Lord of the Admiralty, and the Secretary of State for Foreign Affairs, with an expression of the desire of the Congress that they should be favourably entertained, and, if

approved, be recommended for adoption by foreign governments. The resolution was unanimously adopted.

On motion of Mr. Bowman, seconded by Mr. Lister, medals of honour were presented to the President of the preceding Congress, Prof. Donders, of Utrecht, and to the Secretary-General, Dr. George, of Amsterdam, to Madame Raynaud, as a souvenir of her husband, whose untimely death rendered necessary the reading of his address by his friend Dr. Féréol, and to the readers of the general addresses, Drs. Féréol, of Paris; Billings, of Washington; Pasteur, of Paris, Volkmann, of Halle; and to Prof. Huxley, of London.

Prof. Von Langenbeck moved that the executive committee should convey the thanks of the Congress to those non-members whose hospitality the Congress had received. Adopted.

The President moved that the decision as to the next place of meeting be left to the Executive Committee. Adopted.

Dr. Billings, of Washington, moved that the best thanks of the Congress be tendered to Mr. Mac Cormac, the Hon. Secretary-General, for the able and painstaking manner in which he had successfully discharged the multifarious duties of his laborious office. Adopted.

Prof. Charcot, of Paris, moved a vote of thanks to Sir James Paget, the President, for his services as presiding officer, which was carried with great enthusiasm, the whole meeting rising and cheering.

Sir James Paget said he had now the privilege of returning his thanks for the second time; at first for selecting him as as their president, and now for saying that he had done the work fairly well. If he had worked hard with them all, every day of work had been a day of pleasure, for he had been associated with so many whom he much desired to meet, and had laid the foundation of friendships to make old age happy. (Cheers.) In so vast a work there must have been some lapses. (Cries of "No, no.") If there had, he begged to apologize. The meeting had been one of a rare amount of work, and the time occupied by the sittings of the Sections had been more than that spent in the meetings of the whole thirteen considerable London Medical Societies in a year. It was now time to say good-bye. It was not possible that all the work which they had done should be without good fruit, that all the mental force they had put forth should be lost. He would then say good-bye, not from himself to them, or from them to him, but to all good-bye, in its full meaning, namely, good be with them all in the future, especially that good which comes from doing good. (Cheers.)

The Congress then adjourned *sine die*. After the adjournment a large number of the members went to the Crystal Palace where they informally dined together. Afterward the fountains played, and there was a beautiful display of fireworks. The closing piece consisted of three colossal portraits of Charcot, Paget, and Langenbeck, which, as they became recognizable, were received with the utmost enthusiasm. I. M. H.

Scarlatina in Charleston, South Carolina.

Dr. F. Peyre Porcher, under date of July 20th, writes: "In our last communication we stated, with regard to scarlet fever (which has very much abated), that at the commencement of the epidemic there had been an extraordinary exemption of the coloured race. This was true. The ward physicians and others note that subsequently the disease began to show itself more frequently in negroes, and some deaths have been reported among them.

"It seems to us that, having passed through any epidemic, a physician should have more precise opinions regarding the disease, and his practice should be more fixed and precise with the fresh recollection of his recent experience.

Without pretending to a very extensive one, we have come to these conclusions: Scarlet, like yellow, fever should be treated early; efforts to control the fever should be made *from the beginning*, and the temperature, if possible, not be allowed to remain over 103° for any length of time. As in yellow fever continued high temperature and rapid combustion lead to black vomit and to uræmic poisoning, so in scarlet fever they intensify the tendency to and the grade of the throat affection as well as the congestion of the kidneys. To reduce the temperature and maintain it at a safe standard, the best means are naturally, after a mild laxative, the *early* use of alkaline fever-mixtures containing potash, spiritus mindereri, etc., the frequent application of ice-water to the head and hands, two or three warm baths daily, and greasing the entire surface of the body. Local applications to the throat internally of Labarraque's solution, chlorate of potash, tincture of myrrh, etc., should also be used. This, however, is not the place to go into detail on such matters, but the above we believe to be *essential* for success in the treatment of the disease. We would decidedly favour the trial of prophylactics in all children exposed to this disease and to diphtheria."

Health of New York.—The city's mortality has been somewhat smaller during the past month than in the preceding one. There were, however, 4378 deaths in July, against 3487 in July, 1880. Intense heat prevailed on August 5th, 6th, and 7th, the thermometer registering about 90° in the shade. On these three days 60 cases of insolation were reported. On July 11, 14, 22, and 26 there were 5, 4, 6, and 5 cases of sunstroke, respectively. Two cases of yellow fever have reached the port from Havana during the month. These are the only cases of yellow fever which have been received at quarantine this year. Last year patients sick with that disease arrived at quarantine almost daily from June till October. The special medical corps of the Health Board still continue their work in the tenement districts. Their visits cover the whole of Manhattan Island, this year, for the first time. On August 2d the Board of Health ordered the lodging-house at 61 Thompson St. closed for the reason that 22 undoubted cases of typhus fever were removed from that house between April 8th and July 21st, and that it would probably have become a focus for the disease with the advent of cold weather and the invading army of tramps.

Typhus fever has steadily abated during July. In the sixteenth week of its prevalence (ending July 2d) there were 11 new cases; in the seventeenth week, 10; in the eighteenth week, 24; in the nineteenth week, 19; in the twentieth week (ending July 30), 10 cases. There were, thus, 74 cases in July, against 101 in June and 124 in May. Variola has also diminished to an encouraging extent. While 187 new cases of this disease were reported in June, and 210 in May, only 99 were discovered in July. Measles has also notably diminished, only 231 cases being reported for July, against 430 in June, and 587 in May. Scarlatina has increased from 435 in June, to 575 in July; and diphtheria from 434 in June, to 521 in July.

Dr. Nagle, Registrar of Vital Statistics, has recently published New York's mortality report for the six months ending June 30th. From his report it appears that the deaths from zymotic diseases have increased 40 per cent. during that time. The death-rate from diphtheria is twice as great, and that from scarlet fever five times as great as in the preceding period of six months. The mortality for this year is further shown to be 20 per cent. greater than for a corresponding period in 1880, the actual excess in deaths being more than 3000. The death-rate during the last six months has been about 30 per 1000, while it varied between 24 and 26 per 1000 for the corresponding six months of 1880.

Appointment at the New York University.—Dr. F. R. S. Drake has been appointed Clinical Professor of Practical Medicine in the University Medical College of New York.

—

New York Physicians at the International Medical Congress.—New York was well represented at the International Medical Congress recently held at London, by many of her eminent physicians, among whom may be mentioned Drs. Barker, Flint, Sayre, Mundé, Sands, Arnold, Bosworth, Purdy, Satterthwaite, Schaffer, and Taylor.

—

Regulation that does not Regulate.—The Censors of the New York County Medical Society complain that their efforts for the suppression of unqualified and irregular medical practitioners have not been properly seconded by the grand jury, which body recently dismissed a case in which the law regulating the practice of medicine had been manifestly violated.

—

Meeting of American Ophthalmological Society.—The American Ophthalmological Society held its annual meeting at Newport, R. I., on July 27th and 28th, 1881. The following officers were selected for the ensuing year: President, Dr. H. D. Noyes, of New York; Vice-President, Dr. W. F. Norris, of Philadelphia; Secretary and Treasurer, Dr. R. H. Derby, of New York; Committee on Publication, Drs. D. B. St. John Roosa, R. H. Derby, and E. G. Loring; Corresponding Secretary, Dr. J. S. Prout, of Brooklyn.

—

Organization of the Barren County Medical Society, Kentucky.—The Barren County Medical Society, at Temple Hill, Kentucky, was organized June 20, 1881. Officers as follows: R. H. Grinstead, President, Glasgow; J. J. Jepson, Vice-President, Glasgow; Geo. S. Leach, Secretary, Glasgow; C. T. Grinstead, Corresponding Secretary, Temple Hill; S. T. Batts, Treasurer, Dry Fork.

—

Meeting of the American Otological Society.—The American Otological Society held its fourteenth annual meeting at Newport, R. I., July 26th, 1881, after the transaction of the ordinary business, and listening to papers by Dr. Theobald, of Baltimore; Roosa, of New York; Orne Green, of Boston; Burnett, of Phila.; Kipp, of Newark; Blake, of Boston; Buck, of New York, and others, the Society adjourned to meet next year at Lake George, on the day previous to the meeting of the Ophthalmological Society.

—

Ice for the Sick Poor in New York.—The Earle Guild has inaugurated a novel charity, the object of which is the supplying of the sick poor with ice during the heated term. The circumstances and condition of each applicant for ice will be investigated before relief is extended, unless such applicant be provided with a voucher from a reputable physician. The Guild will issue tickets to families in distress for a two, three, or four weeks' supply of ice, which will be delivered daily anywhere in the city. On Saturday a double quantity will be delivered. Books containing ten orders, each one of which is good for a two weeks' supply, will be sold to the sick, who are able to pay a small sum for relief, at the rate of $5.00.

—

New Summer Cottage Charity.—The Sisters of St. John Baptist, of No. 233 E. 17th Street, New York, propose to erect a house, at some convenient place on Long Island, which will be known as St. Anna's Cottage. The house will be designed to give the benefit of fresh air and recreation to mothers of families,

their high professional standing.

I.

THE AMERICAN JOURNAL OF THE MEDICAL SCIENCES,

EDITED BY I. MINIS HAYS, M.D.,

for more than half a century has maintained its position in the front rank of the medical literature of the world. Cordially supported by the profession of America, it circulates wherever the language is read, and is universally regarded as the national exponent of American medicine—a position to which it is entitled by the distinguished names from every section of the Union which are to be found among its collaborators.* It is issued quarterly, in January, April, July, and October, each number containing about three hundred octavo pages, appropriately illustrated wherever necessary. A large portion of this space is devoted to Original Communications, embracing papers from the most eminent members of the profession throughout the country.

Following this is the REVIEW DEPARTMENT, containing extended reviews by competent writers of prominent new works and topics of the day, together with numerous elaborate Analytical and Bibliographical Notices, giving a fairly complete survey of medical literature.

Then follows the QUARTERLY SUMMARY OF IMPROVEMENTS AND DISCOVERIES IN THE MEDICAL SCIENCES, classified and arranged under different heads, and furnishing a digest of medical progress, abroad and at home.

Thus during the year 1880 the "JOURNAL" contained 67 Original Communications, mostly elaborate in character, 170 Reviews and Bibliographical Notices, and 147 articles in the Quarterly Summaries, illustrated with 47 wood engravings.

That the efforts thus made to maintain the high reputation of the "JOURNAL" are successful, is shown by the position accorded to it in both America and Europe as the leading organ of medical progress:—

This is universally acknowledged as the leading American Journal, and has been conducted by Dr. Hays alone until 1869, when his son was associated with him. We quite agree with the critic, that this journal is second to none in the language, and cheerfully accord to it the first place, for nowhere shall we find more able and more impartial criticism, and nowhere such a repertory of able original articles. Indeed, now that the "British and Foreign Medico-Chirurgical Review" has terminated its career, the American Journal stands without a rival.—*London Med. Times and Gazette*, Nov. 24, 1877.

The best medical journal on the continent.—*Boston Med. and Surg. Journal*, April, 1879.

The present number of the American Journal is an exceedingly good one, and gives every promise of maintaining the well-earned reputation of the review. Our venerable contemporary has our best wishes, and we can only express the hope that it may continue its work with as much vigor and excellence for the next fifty years as it has exhibited in the past.—*London Lancet*, Nov. 24, 1877.

The Philadelphia Medical and Physical Journal issued its first number in 1820, and, after a brilliant career, was succeeded in 1827 by the American Journal of the Medical Sciences, a periodical of world-wide reputation; the ablest and one of the oldest periodicals in the world—a journal which has an unsullied record.—*Grosse's History of American Med. Literature* 1876.

The best medical journal ever published in Europe or America.—*Va. Med. Monthly*, May, 1879.

It is universally acknowledged to be the leading American medical journal, and, in our opinion, is second to none in the language.—*Boston Med. and Surg. Journal*, Oct. 1877.

This is the medical journal of our country to which the American physician abroad will point with the greatest satisfaction, as reflecting the state of medical culture in his country. For a great many years it has been the medium through which our ablest writers have made known their discoveries and observations.—*Address of L. P. Yandell, M.D., before International Med. Congress*, Sept. 1876.

And that it was specifically included in the award of a medal of merit to the Publishers in the Vienna Exhibition in 1873.

The subscription price of the "AMERICAN JOURNAL OF THE MEDICAL SCIENCES" has never been raised during its long career. It is still FIVE DOLLARS per annum; and when paid for in advance, the subscriber receives in addition the "MEDICAL NEWS AND ABSTRACT," making in all nearly 2000 large octavo pages per annum, free of postage.

II.

THE MEDICAL NEWS AND ABSTRACT.

Thirty-eight years ago the "MEDICAL NEWS" was commenced as a monthly to convey to the subscribers of the "AMERICAN JOURNAL" the clinical instruction and

* Communications are invited from gentlemen in all parts of the country. Articles inserted by the Editor are liberally paid for by the publishers.

current information which could not be accommodated in the Quarterly. It consisted of sixteen pages of such matter, together with sixteen more known as the Library Department and devoted to the publishing of books. With the increased progress of science, however, this was found insufficient, and some years since another periodical, known as the "MONTHLY ABSTRACT," was started, and was furnished at a moderate price to subscribers to the "AMERICAN JOURNAL." These two monthlies have been consolidated, under the title of "THE MEDICAL NEWS AND ABSTRACT," and are furnished *free of charge* in connection with the "AMERICAN JOURNAL."

The "NEWS AND ABSTRACT" consists of 64 pages monthly, in a neat cover. It contains a CLINICAL DEPARTMENT in which will be continued the series of ORIGINAL AMERICAN CLINICAL LECTURES, by gentlemen of the highest reputation throughout the United States, together with a choice selection of foreign Lectures and Hospital Notes and Gleanings. Then follows the MONTHLY ABSTRACT, systematically arranged and classified, and presenting five or six hundred articles yearly; and each number concludes with an EDITORIAL and a NEWS DEPARTMENT, giving current professional intelligence, domestic and foreign, the whole fully indexed at the close of each volume, rendering it of permanent value for reference.

As stated above, the subscription price to the "NEWS AND ABSTRACT" is Two Dollars and a Half per annum, invariably in advance, at which rate it ranks as one of the cheapest medical periodicals in the country. But it is also furnished, free of all charge, in commutation with the "AMERICAN JOURNAL OF THE MEDICAL SCIENCES," to all who remit FIVE DOLLARS in advance, thus giving to the subscriber, for that very moderate sum, a complete record of medical progress throughout the world, in the compass of about two thousand large octavo pages.

In this effort to furnish so large an amount of practical information at a price so unprecedentedly low, and thus place it within the reach of every member of the profession, the publishers confidently anticipate the friendly aid of all who feel an interest in the dissemination of sound medical literature. They trust, especially, that the subscribers to the "AMERICAN MEDICAL JOURNAL," will call the attention of their acquaintances to the advantages thus offered, and that they will be sustained in the endeavor to permanently establish medical periodical literature on a footing of cheapness never heretofore attempted.

PREMIUM FOR OBTAINING NEW SUBSCRIBERS TO THE "JOURNAL."

Any gentleman who will remit the amount for two subscriptions for 1881, one of which at least must be for a *new subscriber*, will receive as a PREMIUM, free by mail, a copy of any one of the following recent works:—

"SEILER ON THE THROAT" (see p. 19),
"BARNES'S MANUAL OF MIDWIFERY" (see p. 24),
"BROWNE ON THE USE OF THE OPHTHALMOSCOPE" (see p. 29),
"FLINT'S ESSAYS ON CONSERVATIVE MEDICINE" (see p. 15),
"STURGES'S CLINICAL MEDICINE" (see p. 15),
"TANNER'S CLINICAL MANUAL" (see p. 5),
"WEST ON NERVOUS DISORDERS OF CHILDREN" (see p. 21).

*** Gentlemen desiring to avail themselves of the advantages thus offered will do well to forward their subscriptions at an early day, in order to insure the receipt of complete sets for the year 1881.

☞ The safest mode of remittance is by bank check or postal money order, drawn to the order of the undersigned. Where these are not accessible, remittances for the "JOURNAL" may be made at the risk of the publishers, by forwarding in REGISTERED letters. Address,

HENRY C. LEA'S SON & Co., Nos. 706 and 708 Sansom St., Phila., Pa.

DUNGLISON (ROBLEY), M.D.,

Late Professor of Institutes of Medicine in Jefferson Medical College, Philadelphia.

MEDICAL LEXICON; A DICTIONARY OF MEDICAL SCIENCE: Containing a concise explanation of the various Subjects and Terms of Anatomy, Physiology, Pathology, Hygiene, Therapeutics, Pharmacology, Pharmacy, Surgery, Obstetrics, Medical Jurisprudence and Dentistry. Notices of Climate and of Mineral Waters; Formulæ for Officinal, Empirical and Dietetic Preparations; with the Accentuation and Etymology of the Terms, and the French and other Synonymes; so as to constitute a French as well as English Medical Lexicon. A New Edition. Thoroughly Revised, and very greatly Modified and Augmented. By RICHARD J. DUNGLISON, M.D. In one very large and handsome royal octavo volume of over 1100 pages. Cloth, $6 50; leather, raised bands, $7 50; half Russia, $8. (*Lately Issued.*)

The object of the author from the outset has not been to make the work a mere lexicon or dictionary of terms, but to afford, under each, a condensed view of its various medical relations, and thus to render the work an epitome of the existing condition of medical science. Starting with this view, the immense demand which has existed for the work has enabled him, in repeated revisions, to augment its completeness and usefulness, until at length it has attained the position of a recognised and standard authority wherever the language is spoken.

Special pains have been taken in the preparation of the present edition to maintain this enviable reputation. During the ten years which have elapsed since the last revision, the additions to the nomenclature of the medical sciences have been greater than perhaps in any similar period of the past, and up to the time of his death the author labored assiduously to incorporate everything requiring the attention of the student or practitioner. Since then, the editor has been equally industrious, so that the additions to the vocabulary are more numerous than in any previous revision. Especial attention has been bestowed on the accentuation, which will be found marked on every word. The typographical arrangement has been much improved, rendering reference much more easy, and every care has been taken with the mechanical execution. The work has been printed on new type, small but exceedingly clear, with an enlarged page, so that the additions have been incorporated with an increase of but little over a hundred pages, and the volume now contains the matter of at least four ordinary octavos.

A book well known to our readers, and of which every American ought to be proud. When the learned author of the work passed away, probably all of us feared lest the book should not maintain its place in the advancing science whose terms it defines. Fortunately, Dr. Richard J. Dunglison, having assisted his father in the revision of several editions of the work, and having been, therefore, trained in the methods and imbued with the spirit of the book, has been able to edit it, not in the patchwork manner so dear to the heart of book editors, so repulsive to the taste of intelligent book readers, but to edit it as a work of the kind should be edited—to carry it on steadily, without jar or interruption, along the grooves of thought it has travelled during its lifetime. To show the magnitude of the task which Dr. Dunglison has assumed and carried through, it is only necessary to state that more than six thousand new subjects have been added in the present edition.—*Phila. Med. Times*, Jan. 3, 1874.

About the first book purchased by the medical student is the Medical Dictionary. The lexicon explanatory of technical terms is simply a *sine qua non*. In a science so extensive, and with such collaterals as medicine, it is as much a necessity also to the practising physician. To meet the wants of students and most physicians, the dictionary must be condensed while comprehensive, and practical while perspicacious. It was because Dunglison's met these indications that it became at once the dictionary of general use wherever medicine was studied in the English language. In no former revision have the alterations and additions been so great. More than six thousand new subjects and terms have been added. The chief terms have been set in black letter, while the derivatives follow in small caps; an arrangement which greatly facilitates reference. We may safely confirm the hope ventured by the editor "that the work, which possesses for him a filial as well as an individual interest, will be found worthy a continuance of the position so long accorded to it as a standard authority."—*Cincinnati Clinic*, Jan. 10, 1874.

It has the rare merit that it certainly has no rival in the English language for accuracy and extent of references.—*London Medical Gazette*.

As a standard work of reference, as one of the best, if not the very best, medical dictionary in the English language, Dunglison's work has been well known for about forty years, and needs no words of praise on our part to recommend it to the members of the medical, and, likewise, of the pharmaceutical profession. The latter especially are in need of such a work, which gives ready and reliable information on thousands of subjects and terms which they are liable to encounter in pursuing their daily avocations, but with which they cannot be expected to be familiar. The work before us fully supplies this want.—*Am. Journ. of Pharm.*, Feb. 1874.

A valuable dictionary of the terms employed in medicine and the allied sciences, and of the relations of the subjects treated under each head. It reflects great credit on its able American author, and well deserves the authority and popularity it has obtained.—*British Med. Journ.*, Oct. 31, 1874.

Few works of this class exhibit a grander monument of patient research and of scientific lore. The extent of the sale of this lexicon is sufficient to testify to its usefulness, and to the great service conferred by Dr. Robley Dunglison on the profession, and indeed on others, by its issue.—*London Lancet*, May 13, 1876.

HOBLYN (RICHARD D.), M.D.

A DICTIONARY OF THE TERMS USED IN MEDICINE AND THE COLLATERAL SCIENCES. Revised, with numerous additions, by ISAAC HAYS, M.D., Editor of the "American Journal of the Medical Sciences." In one large royal 12mo. volume of over 500 double-columned pages; cloth, $1 50; leather, $2 00.

It is the best book of definitions we have, and ought always to be upon the student's table.—Southern Med. and Surg. Journal.

RODWELL (G. F.), F.R.A.S., &c.

A DICTIONARY OF SCIENCE: Comprising Astronomy, Chemistry, Dynamics, Electricity, Heat, Hydrodynamics, Hydrostatics, Light, Magnetism, Mechanics, Meteorology, Pneumatics, Sound and Statics. Preceded by an Essay on the History of the Physical Sciences. In one handsome octavo volume of 594 pages, with many illustrations: cloth, $5.

A CENTURY OF AMERICAN MEDICINE. 1776–1876. By Doctors E. H. Clarke, H. J. Bigelow, S. D. Gross, T. G. Thomas and J. S. Billings. In one very handsome 12mo. volume of about 350 pages: cloth, $2 25.

This work appeared in the pages of the American Journal of the Medical Sciences during the year 1876. As a detailed account of the development of medical science in America, by gentlemen of the highest authority in their respective departments, the profession will no doubt welcome it in a form adapted for preservation and reference.

NEILL (JOHN), M.D., and SMITH (FRANCIS G.), M.D.,
Prof. of the Institutes of Medicine in the Univ. of Penna.

AN ANALYTICAL COMPENDIUM OF THE VARIOUS BRANCHES OF MEDICAL SCIENCE; for the Use and Examination of Students. A new edition, revised and improved. In one very large and handsomely printed royal 12mo. volume, of about one thousand pages, with 374 wood-cuts, cloth, $4; strongly bound in leather, with raised bands, $4 75.

HARTSHORNE (HENRY), M.D.,
Professor of Hygiene in the University of Pennsylvania.

A CONSPECTUS OF THE MEDICAL SCIENCES; containing Handbooks on Anatomy, Physiology, Chemistry, Materia Medica, Practical Medicine, Surgery and Obstetrics. Second Edition, thoroughly revised and improved. In one large royal 12mo. volume of more than 1000 closely printed pages, with 477 illustrations on wood. Cloth, $4 25; leather, $5 00.

We can say with the strictest truth that it is the best work of the kind with which we are acquainted. It embodies in a condensed form all recent contributions to practical medicine, and is therefore useful to every busy practitioner throughout our country, besides being admirably adapted to the use of students of medicine. The book is faithfully and ably executed.—*Charleston Med. Journ.*, April, 1875

The work is intended as an aid to the medical student, and as such appears to admirably fulfil its object by its excellent arrangement, the full compilation of facts, the perspicuity and terseness of language, and the clear and instructive illustrations in some parts of the work.—*American Journ. of Pharmacy*, Philadelphia, July, 1874.

The volume will be found useful, not only to students, but to many others who may desire to refresh their memories with the smallest possible expenditure of time.—*N. Y. Med. Journal*, Sept. 1874.

The student will find this the most convenient and useful book of the kind on which he can lay his hand.—*Pacific Med. and Surg. Journ.*, Aug. 1874.

This is the best book of its kind that we have ever examined. It is an honest, accurate, and concise compend of medical sciences, as fairly as possible representing their present condition. The changes and the additions have been so judicious and thorough as to render it, so far as it goes, entirely trustworthy. If students must have a conspectus, they will be wise to procure that of Dr. Hartshorne.—*Detroit Rev. of Med and Pharm.*, Aug 1874.

The work before us has many redeeming features not possessed by others, and is the best we have seen. Dr. Hartshorne exhibits much skill in condensation. It is well adapted to the physician in active practice, who can give but limited time to the familiarizing of himself with the important changes which have been made since he attended lectures. The manual of physiology has also been improved and gives the most comprehensive view of the latest advances in the science possible in the space devoted to the subject. The mechanical execution of the book leaves nothing to be wished for.—*Peninsular Journal of Medicine*, Sept. 1874.

After carefully looking through this conspectus, we are constrained to say that it is the most complete work, especially in its illustrations, of its kind that we have seen.—*Cincinnati Lancet*, Sept. 1874.

The favor with which the first edition of this Compendium was received, was an evidence of its various excellences. The present edition bears evidence of a careful and thorough revision. Dr. Hartshorne possesses a happy faculty of seizing upon the salient points of each subject, and of presenting them in a concise and yet perspicuous manner.—*Leavenworth Med. Herald*, Oct. 1874

LUDLOW (J. L.), M.D.

A MANUAL OF EXAMINATIONS upon Anatomy, Physiology, Surgery, Practice of Medicine, Obstetrics, Materia Medica, Chemistry, Pharmacy and Therapeutics. To which is added a Medical Formulary. Third edition, thoroughly revised and greatly extended and enlarged. With 370 illustrations In one handsome royal 12mo. volume of 816 large pages. Cloth, $3 25; leather, $3 75.

The arrangement of this volume in the form of question and answer renders it especially suitable for the office examination of students, and for those preparing for graduation.

TANNER (THOMAS HAWKES), M.D., &c.

A MANUAL OF CLINICAL MEDICINE AND PHYSICAL DIAGNOSIS. Third American from the Second London Edition. Revised and Enlarged by TILBURY FOX, M. D., Physician to the Skin Department in University College Hospital, London, &c. In one neat volume, small 12mo., of about 375 pages, cloth, $1 50.

*** On page 3, it will be seen that this work is offered as a premium for procuring new subscribers to the "AMERICAN JOURNAL OF THE MEDICAL SCIENCES."

GRAY (HENRY), F.R.S.,
Lecturer on Anatomy at St. George's Hospital, London.

ANATOMY, DESCRIPTIVE AND SURGICAL. The Drawings by H. V. CARTER, M.D., and Dr. WESTMACOTT. The Dissections jointly by the AUTHOR and Dr. CARTER. With an Introduction on General Anatomy and Development by T. HOLMES, M.A., Surgeon to St. George's Hospital. A new American, from the Eighth enlarged and improved London edition. To which is added "LANDMARKS, MEDICAL AND SURGICAL," by LUTHER HOLDEN, F.R.C.S., author of "Human Osteology," "A Manual of Dissections," etc. In one magnificent imperial octavo volume of 983 pages, with 522 large and elaborate engravings on wood. Cloth, $6; leather, raised bands, $7; half Russia, $7 50.

The author has endeavored in this work to cover a more extended range of subjects than is customary in the ordinary text-books, by giving not only the details necessary for the student, but also the application of those details in the practice of medicine and surgery, thus rendering it both a guide for the learner, and an admirable work of reference for the active practitioner. The engravings form a special feature in the work, many of them being the size of nature, nearly all original, and having the names of the various parts printed on the body of the cut, in place of figures of reference, with descriptions at the foot. They thus form a complete and splendid series, which will greatly assist the student in obtaining a clear idea of Anatomy, and will also serve to refresh the memory of those who may find in the exigencies of practice the necessity of recalling the details of the dissecting room; while combining, as it does, a complete Atlas of Anatomy, with a thorough treatise on systematic, descriptive and applied Anatomy, the work will be found of essential use to all physicians who receive students in their offices, relieving both preceptor and pupil of much labor in laying the groundwork of a thorough medical education.

Since the appearance of the last American Edition, the work has received three revisions at the hands of its accomplished editor, Mr. Holmes, who has sedulously introduced whatever has seemed requisite to maintain its reputation as a complete and authoritative standard text-book and work of reference. Still further to increase its usefulness, there has been appended to it the recent work by the distinguished anatomist, Mr. Luther Holden—"Landmarks, Medical and Surgical"—which gives in a clear, condensed and systematic way, all the information by which the practitioner can determine from the external surface of the body the position of internal parts. Thus complete, the work, it is believed, will furnish all the assistance that can be rendered by type and illustration in anatomical study. No pains have been spared in the typographical execution of the volume, which will be found in all respects superior to former issues. Notwithstanding the increase of size, amounting to over 100 pages and 57 illustrations, it will be kept, as heretofore, at a price rendering it one of the cheapest works ever offered to the American profession.

The recent work of Mr. Holden, which was noticed by us on p. 53 of this volume, has been added as an appendix, so that, altogether, this is the most practical and complete anatomical treatise available to American students and physicians. The former finds in it the necessary guide in making dissections; a very comprehensive chapter on minute anatomy; and about all that can be taught him on general and special anatomy; while the latter, in its treatment of each region from a surgical point of view, and in the valuable addition of Mr. Holden, will find all that will be essential to him in his practice.—*New Remedies*, Aug. 1878.

This work is as near perfection as one could possibly or reasonably expect any book intended as a text-book or a general reference book on anatomy to be. The American publisher deserves the thanks of the profession for appending the recent work of Mr. Holden, "*Landmarks, Medical and Surgical*," which has already been commended as a separate book. The latter work—treating of topographical anatomy—has become an essential to the library of every intelligent practitioner. We know of no book that can take its place, written as it is by a most distinguished anatomist. It would be simply a waste of words to say anything further in praise of Gray's Anatomy, the text-book in almost every medical college in this country, and the daily reference book of every practitioner who has occasion to consult his books on anatomy. The work is simply indispensable, especially this present American edition.—*Va. Med. Monthly*, Sept. 1878.

The addition of the recent work of Mr. Holden, as an appendix, renders this the most practical and complete treatise available to American students, who find in it a comprehensive chapter on minute anatomy, about all that can be taught on general and special anatomy, while its treatment of each region, from a surgical point of view, in the valuable section by Mr Holden, is all that will be essential to them in practice.—*Ohio Medical Recorder*, Aug 1878.

It is difficult to speak in moderate terms of this new edition of "Gray." It seems to be as nearly perfect as it is possible to make a book devoted to any branch of medical science. The labors of the eminent men who have successively revised the eight editions through which it has passed, would seem to leave nothing for future editors to do. The addition of Holden's "Landmarks" will make it as indispensable to the practitioner of medicine and surgery as it has been heretofore to the student. As regards completeness, ease of reference, utility, beauty, and cheapness, it has no rival. No student should enter a medical school without it; no physician can afford to have it absent from his library.—*St. Louis Clin. Record*, Sept. 1878.

ALSO FOR SALE SEPARATE—

HOLDEN (LUTHER), F.R.C.S.,
Surgeon to St. Bartholomew's and the Foundling Hospitals.

LANDMARKS, MEDICAL AND SURGICAL. Second American, from the Latest Revised English Edition, with additions by W. W. KEEN, M.D., Prof. of Artistic Anatomy in the Penna. Academy of the Fine Arts, formerly Lecturer on Anatomy in the Phila. School of Anatomy. In one handsome 12mo. volume, of about 140 pages. (*Nearly Ready.*)

HEATH (CHRISTOPHER), F.R.C.S.,
Teacher of Operative Surgery in University College, London.

PRACTICAL ANATOMY: A Manual of Dissections. From the Second revised and improved London edition. Edited, with additions, by W. W. KEEN, M. D., Lecturer on Pathological Anatomy in the Jefferson Medical College, Philadelphia. In one handsome royal 12mo. volume of 578 pages, with 247 illustrations. Cloth, $3 50; leather, $4 00.

ALLEN (*HARRISON*), *M.D.*

Professor of Physiology in the Univ. of Pa.

A SYSTEM OF HUMAN ANATOMY; INCLUDING ITS MEDICAL and Surgical Relations.

For the Use of Practitioners and Students of Medicine. With an Introductory Chapter on Histology. By E. O. SHAKESPEARE, M.D., Ophthalmologist to the Phila. Hosp. In one large and handsome quarto volume, with several hundred original illustrations on lithographic plates, and numerous wood-cuts in the text. (*Shortly.*)

In this elaborate work, which has been in active preparation for several years, the author has sought to give, not only the details of descriptive anatomy in a clear and condensed form, but also the practical applications of the science to medicine and surgery. The work thus has claims upon the attention of the general practitioner, as well as of the student, enabling him not only to refresh his recollections of the dissecting room, but also to recognize the significance of all variations from normal conditions. The marked utility of the object thus sought by the author is self-evident, and his long experience and assiduous devotion to its thorough development are a sufficient guarantee of the manner in which his aims have been carried out. No pains have been spared with the illustrations. Those of normal anatomy are from original dissections, drawn on stone by Mr. Hermann Faber, with the name of every part clearly engraved upon the figure, after the manner of "Holden" and "Gray," and in every typographical detail it will be the effort of the publishers to render the volume worthy of the very distinguished position which is anticipated for it.

ELLIS (*GEORGE VINER*).

Emeritus Professor of Anatomy in University College, London.

DEMONSTRATIONS OF ANATOMY; Being a Guide to the Knowledge of the Human Body by Dissection.

By GEORGE VINER ELLIS, Emeritus Professor of Anatomy in University College, London. From the Eighth and Revised London Edition. In one very handsome octavo volume of over 700 pages, with 256 illustrations. Cloth, $4.25; leather, $5.25. (*Lately Issued.*)

This work has long been known in England as the leading authority on practical anatomy, and the favorite guide in the dissecting-room, as is attested by the numerous editions through which it has passed. In the last revision, which has just appeared in London, the accomplished author has sought to bring it on a level with the most recent advances of science by making the necessary changes in his account of the microscopic structure of the different organs, as developed by the latest researches in textural anatomy.

Ellis's Demonstrations is the favorite text-book of the English student of anatomy. In passing through eight editions it has been so revised and adapted to the needs of the student that it would seem that it had almost reached perfection in this special line. The descriptions are clear, and the methods of pursuing anatomical investigations are given with such detail that the book is honestly entitled to its name.—*St. Louis Clinical Record*, June, 1879.

The success of this old manual seems to be as well deserved in the present as in the past volumes. The book seems destined to maintain yet for years its leadership over the English manuals upon dissecting.—*Phila. Med. Times*, May 24, 1879.

As a dissector, or a work to have in hand and studied while one is engaged in dissecting, we regard it as the very best work extant, which is certainly saying a very great deal. As a text-book to be studied in the dissecting-room, it is superior to any of the works upon anatomy.—*Cincinnati Med. News*, May 24, 1879.

We most unreservedly recommend it to every practitioner of medicine who can possibly get it.—*Va. Med. Monthly*, June, 1879.

WILSON (*ERASMUS*), *F.R.S.*

A SYSTEM OF HUMAN ANATOMY, General and Special.

Edited by W. H. GOBRECHT, M.D., Professor of General and Surgical Anatomy in the Medical College of Ohio. Illustrated with three hundred and ninety-seven engravings on wood. In one large and handsome octavo volume, of over 600 pages; cloth, $4; leather, $5.

SMITH (*HENRY H.*), *M.D.*, *and* *HORNER* (*WILLIAM E.*), *M.D.*,

Prof. of Surgery in the Univ. of Penna., &c. *Late Prof. of Anatomy in the Univ. of Penna.*

AN ANATOMICAL ATLAS; Illustrative of the Structure of the Human Body.

In one volume, large imperial octavo, cloth, with about six hundred and fifty beautiful figures. $4 50.

SCHÄFER (*EDWARD ALBERT*), *M.D.*,

Assistant Professor of Physiology in University College, London.

A COURSE OF PRACTICAL HISTOLOGY: Being an Introduction to the Use of the Microscope.

In one handsome royal 12mo. volume of 304 pages, with numerous illustrations: cloth, $2 00. (*Lately Issued.*)

HORNER'S SPECIAL ANATOMY AND HISTOLOGY. Eighth edition, extensively revised and modified. In 2 vols. 8vo., of over 1000 pages, with 320 wood-cuts: cloth, $6 00.

SHARPEY AND QUAIN'S HUMAN ANATOMY. Revised, by JOSEPH LEIDY, M.D., Prof. of Anat. in Univ. of Penn. In two octavo vols. of about 1300 pages, with 511 illustrations. Cloth, $6 00.

BELLAMY'S STUDENT'S GUIDE TO SURGICAL ANATOMY: A Text-book for Students preparing for their Pass Examination. With engravings on wood. In one handsome royal 12mo. volume. Cloth, $2 25.

CLELAND'S DIRECTORY FOR THE DISSECTION OF THE HUMAN BODY. In one small volume, royal 12mo. of 182 pages: cloth $1 25.

HARTSHORNE'S HANDBOOK OF ANATOMY AND PHYSIOLOGY. Second edition, revised. In one royal 12mo. vol., with 220 wood-cuts; cloth $1 75.

DALTON (*J. C.*), *M.D.*,

Professor of Physiology in the College of Physicians and Surgeons, New York, &c.

A TREATISE ON HUMAN PHYSIOLOGY. Designed for the use of Students and Practitioners of Medicine. Sixth edit., thoroughly revised and enlarged, with three hundred and sixteen illustrations on wood. In one very beautiful octave volume, of over 800 pages. Cloth, $5 50; leather, $6 50; half Russia, $7.

During the past few years several new works on physiology, and new editions of old works, have appeared, competing for the favor of the medical student, but none will rival this new edition of Dalton. As now enlarged, it will be found also to be, in general, a satisfactory work of reference for the practitioner.—*Chicago Med. Journ. and Examiner*, Jan. 1876.

Prof. Dalton has discussed conflicting theories and conclusions regarding physiological questions with a fairness, a fulness, and a conciseness which lend freshness and vigor to the entire book. But his discussions have been so guarded by a refusal of admission to those speculative and theoretical explanations, which at best exist in the minds of observers themselves as only probabilities, that none of his readers need be led into grave errors while making them a study.—*The Medical Record*, Feb. 19, 1876.

For clearness and perspicuity, Dalton's Physiology commended itself to the student years ago, and was a pleasant relief from the verbose productions which it supplanted. Physiology has, however, made many advances since then—and while the style has been preserved intact, the work in the present edition has been brought up fully abreast of the times. The new chemical notation and nomenclature have also been introduced into the present edition. Notwithstanding the multiplicity of text-books on physiology, this will lose none of its old time popularity. The mechanical execution of the work is all that could be desired.—*Peninsular Journal of Medicine*, Dec. 1875.

This popular text-book on physiology comes to us in its sixth edition with the addition of about fifty per cent. of new matter, chiefly in the departments of pathological chemistry and the nervous system, where the principal advances have been realized. With so thorough revision and additions, that keep the work well up to the times, its continued popularity may be confidently predicted, notwithstanding the competition it may encounter. The publisher's work is admirably done.—*St. Louis Med. and Surg. Journ.*, Dec. 1875

The revision of this great work has brought it forward with the physiological advances of the day, and renders it, as it has ever been, the finest work for students extant.—*Nashville Journ. of Med. and Surg.*, Jan. 1876.

CARPENTER (*WILLIAM B.*), *M. D., F. R. S., F.G.S., F.L.S.*,

Registrar to University of London, etc.

PRINCIPLES OF HUMAN PHYSIOLOGY; Edited by HENRY POWER, M.B. Lond., F.R.C.S., Examiner in Natural Sciences, University of Oxford. A new American from the Eighth Revised and Enlarged English Edition, with Notes and Additions, by FRANCIS G. SMITH, M.D., Professor of the Institutes of Medicine in the University of Pennsylvania, etc. In one very large and handsome octavo volume, of 1083 pages, with two plates and 373 engs. on wood. Cloth, $5 50; leather, $6 50; half Russia, $7.

We have been agreeably surprised to find the volume so complete in regard to the structure and functions of the nervous system in all its relations, a subject that, in many respects, is one of the most difficult of all, in the whole range of physiology, upon which to produce a full and satisfactory treatise of the class to which the one before us belongs. The additions by the American editor give to the work as it is a considerable value beyond that of the last English edition. In conclusion, we can give our cordial recommendation to the work as it now appears. The editors have, with their additions to the only work on physiology in our language that, in the fullest sense of the word, is the production of a philosopher as well as a physiologist, brought it up as fully as could be expected, if not desired, to the standard of our knowledge of its subject at the present day. It will deservedly maintain the place it has always had in the favor of the medical profession.—*Journ. of Nervous and Mental Disease*, April, 1877.

Such enormous advances have recently been made in our physiological knowledge, that what was perfectly new a year or two ago, looks now as if it had been a received and established fact for years. In this encyclopædic way it is unrivalled. Here, as it seems to us, is the great value of the book; one is safe in sending a student to it for information on almost any given subject, perfectly certain of the fulness of information it will convey, and well satisfied of the accuracy with which it will there be found stated.—*London Med. Times and Gazette*, Feb. 17, 1877.

The merits of "Carpenter's Physiology" are so widely known and appreciated that we need only allude briefly to the fact that in the latest edition will be found a comprehensive embodiment of the results of recent physiological investigation. Care has been taken to preserve the practical character of the original work. In fact the entire work has been brought up to date, and bears evidence of the amount of labor that has been bestowed upon it by its distinguished editor, Mr. Henry Power. The American editor has made the latest additions, in order fully to cover the time that has elapsed since the last English edition.—*N. Y. Med. Journal*, Jan. 1877.

FOSTER (*MICHAEL*), *M.D., F.R.S.*,

Prof. of Physiology in Cambridge Univ., England.

TEXT-BOOK OF PHYSIOLOGY. Second American from the Latest English Edition. Edited, with Extensive Notes and Additions, by EDWARD T. REICHERT, M.D., Late Demonstrator of Experimental Therapeutics in the Univ. of Penna. In one handsome royal 12mo. volume of about 1000 pages, with 260 illust. (*Nearly Ready.*)

In the preparation of a second American edition of Mr. Foster's Physiology, the editor has endeavored to render it more than ever acceptable to the student as a clear and comprehensive text-book, presenting the science in its latest developments. The original work being an exposition of functional, rather than general physiology, it seemed desirable to introduce the details of structure, in order to render more intelligible to the student the views and theories of the science. These the editor has added, in as concise a manner as possible; and in aid of this end has freely introduced illustrations from recognized authorities.

LEHMANN'S MANUAL OF CHEMICAL PHYSIOLOGY. Translated from the German, with Notes and Additions, by J. CHESTON MORRIS, M.D. With illustrations on wood. In one octavo volume of 336 pages. Cloth, $2 25.

LEHMANN'S PHYSIOLOGICAL CHEMISTRY. Complete in two large octavo volumes of 1200 pages, with 200 illustrations; cloth, $6.

ATTFIELD (JOHN), Ph.D.,

Professor of Practical Chemistry to the Pharmaceutical Society of Great Britain, &c.

CHEMISTRY, GENERAL, MEDICAL AND PHARMACEUTICAL;

Including the Chemistry of the U. S. Pharmacopœia. A Manual of the General Principles of the Science, and their Application to Medicine and Pharmacy. Eighth edition, revised by the author. In one handsome royal 12mo. volume of 700 pages, with illustrations. Cloth, $2 50; leather, $3 00. (*Now Ready.*)

We have repeatedly expressed our favorable opinion of this work, and on the appearance of a new edition of it, little remains for us to say, except that we expect this eighth edition to be as indispensable to us as the seventh and previous editions have been. While the general plan and arrangement have been adhered to, new matter has been added covering the observations made since the former edition. The present differs from the preceding one chiefly in these alterations and in about ten pages of useful tables added in the appendix.—*Am. Journ. of Pharmacy*, May, 1879.

A standard work like Attfield's Chemistry need only be mentioned by its name, without further comments. The present edition contains such alterations and additions as seemed necessary for the demonstration of the latest developments of chemical principles, and the latest applications of chemistry to pharmacy. The author has bestowed arduous labor on the revision, and the extent of the information thus introduced may be estimated from the fact that the index contains three hundred new references relating to additional material.—*Druggists' Circular and Chemical Gazette*, May, 1879.

This very popular and meritorious work has now reached its eighth edition, which fact speaks in the highest terms in commendation of its excellence. It has now become the principal text-book of chemistry in all the medical colleges in the United States. The present edition contains such alterations and additions as seemed necessary for the demonstration of the latest developments of chemical principles, and the latest applications of chemistry to pharmacy. It is scarcely necessary for us to say that it exhibits chemistry in its present advanced state.—*Cincinnati Medical News*, April, 1879.

The popularity which this work has enjoyed is owing to the original and clear disposition of the facts of the science, the accuracy of the details, and the omission of much which freights many treatises heavily without bringing corresponding instruction to the reader. Dr. Attfield writes for students, and primarily for medical students; he always has an eye to the pharmacopœia and its officinal preparations; and he is continually putting the matter in the text so that it responds to the questions with which each section is provided. Thus the student learns easily, and can always refresh and test his knowledge.—*Med. and Surg. Reporter*, April 19, '79.

We noticed only about two years and a half ago the publication of the preceding edition, and remarked upon the exceptionally valuable character of the work. The work now includes the whole of the chemistry of the pharmacopœia of the United States, Great Britain, and India.—*New Remedies*, May, 1879.

GREENE (WILLIAM H.), M.D.,

Demonstrator of Chemistry in Med. Dept., Univ. of Penna.

A MANUAL OF MEDICAL CHEMISTRY. For the Use of Students.

Based upon Bowman's Medical Chemistry. In one royal 12mo. volume of 312 pages With illustrations. Cloth, $1 75. (*Now Ready.*)

It is well written, and gives the latest views on vital chemistry, a subject with which most physicians are not sufficiently familiar. To those who may wish to improve their knowledge in that direction, we can heartily recommend this work as being worthy of a careful perusal.—*Phila. Med. and Surg. Reporter*, April 24, 1880.

The little work before us is one which we think will be studied with pleasure and profit. The descriptions, though brief, are clear, and in most cases sufficient for the purpose This book will, in nearly all cases, meet general approval.—*Am. Journ. of Pharmacy*, April, 1880.

CLASSEN (ALEXANDER),

Professor in the Royal Polytechnic School, Aix-la-Chapelle.

ELEMENTARY QUANTITATIVE ANALYSIS. Translated with

notes and additions by EDGAR F. SMITH, Ph.D., Assistant Prof. of Chemistry in the Towne Scientific School, Univ. of Penna. In one handsome royal 12mo. volume, of 324 pages, with illustrations; cloth, $2 00. (*Lately Issued.*)

It is probably the best manual of an elementary nature extant, insomuch as its methods are the best. It teaches by examples, commencing with single determinations, followed by separations, and then advancing to the analysis of minerals and such products as are met with in applied chemistry. It is an indispensable book for students in chemistry.—*Boston Journ. of Chemistry*, Oct. 1878.

GALLOWAY (ROBERT), F.C.S.,

Prof of Applied Chemistry in the Royal College of Science for Ireland, etc.

A MANUAL OF QUALITATIVE ANALYSIS. From the Fifth London Edition.

In one neat royal 12mo. volume, with illustrations; cloth, $2 75.

REMSEN (IRA), M.D., Ph.D.,

Professor of Chemistry in the Johns Hopkins University, Baltimore.

PRINCIPLES OF THEORETICAL CHEMISTRY, with special reference

to the Constitution of Chemical Compounds. In one handsome royal 12mo. vol. of over 232 pages: cloth, $1 50.

BOWMAN'S INTRODUCTION TO PRACTICAL CHEMISTRY, INCLUDING ANALYSIS. Sixth American, from the Sixth and revised London edition With numerous illustrations. In one neat vol., royal 12mo., cloth, $2 25.

WÖHLER AND FITTIG'S OUTLINES OF ORGANIC CHEMISTRY. Translated, with additions, from the Eighth German Edition. By IRA REMSEN, M.D., Ph.D., Prof. of Chemistry and Physics in Williams College, Mass. In one volume, royal 12mo. of 550 pp., cloth, $3.

FOWNES (GEORGE), Ph.D.

A MANUAL OF ELEMENTARY CHEMISTRY; Theoretical and Practical.

Revised and corrected by HENRY WATTS, B.A., F.R.S., author of "A Dictionary of Chemistry," etc. With a colored plate, and one hundred and seventy-seven illustrations. A new American, from the Twelfth and enlarged London edition. Edited by ROBERT BRIDGES, M.D. In one large royal 12mo. volume, of over 1000 pages; cloth, $2 75; leather, $3 25. (*Lately Issued.*)

This work, inorganic and organic, is complete in one convenient volume. In its earliest editions it was fully up to the latest advancements and theories of that time. In its present form, it presents, in a remarkably convenient and satisfactory manner, the principles and leading facts of the chemistry of *to-day*. Concerning the manner in which the various subjects are treated, much deserves to be said, and mostly, too, in praise of the book. A review of such a work as *Fownes's Chemistry* within the limits of a book-notice for a medical weekly is simply out of the question.—*Cincinnati Lancet and Clinic*, Dec. 14, 1878.

When we state that, in our opinion, the present edition sustains in every respect the high reputation which its predecessors have acquired and enjoyed, we express therewith our full belief in its intrinsic value as a text-book and work of reference.—*Am. Journ. of Pharm.*, Aug. 1878.

The conscientious care which has been bestowed upon it by the American and English editors renders it still, perhaps, the best book for the student and the practitioner who would keep alive the acquisitions of his student days. It has, indeed, reached a somewhat formidable magnitude with its more than a thousand pages, but with less than this no fair representation of chemistry as it now is can be given. The type is small but very clear, and the sections are very lucidly arranged to facilitate study and reference.—*Med and Surg. Reporter*, Aug 3, 1878.

The work is too well known to American students to need any extended notice; suffice it to say that the revision by the English editor has been faithfully done, and that Professor Bridges has added some fresh and valuable matter, especially in the inorganic chemistry. The book has always been a favorite in this country, and in its new shape bids fair to retain all its former *prestige*.—*Boston Jour. of Chemistry*, Aug. 1878.

It will be entirely unnecessary for us to make any remarks relating to the general character of Fownes' Manual. For over twenty years it has held *the* foremost place as a text-book, and the elaborate and thorough revisions which have been made from time to time leave little chance for any wide awake rival to step before it.—*Canadian Pharm. Jour.*, Aug. 1878.

As a manual of chemistry it is without a superior in the language.—*Md. Med. Jour.*, Aug. 1878.

BLOXAM (C. L.),

Professor of Chemistry in King's College, London.

CHEMISTRY, INORGANIC AND ORGANIC.

From the Second London Edition. In one very handsome octavo volume, of 700 pages, with about 300 illustrations. Cloth, $4 00; leather, $5 00.

We have in this work a complete and most excellent text-book for the use of schools, and can heartily recommend it as such.—*Boston Med. and Surg. Journ.*, May 28, 1874.

The above is the title of a work which we can most conscientiously recommend to students of chemistry. It is as easy as a work on chemistry could be made, at the same time that it presents a full account of that science as it now stands. We have spoken of the work as admirably adapted to the wants of students; it is quite as well suited to the requirements of practitioners who wish to review their chemistry, or have occasion to refresh their memories on any point relating to it. In a word, it is a book to be read by all who wish to know what is the chemistry of the present day.—*American Practitioner*, Nov. 1873.

It would be difficult for a practical chemist and teacher to find any material fault with this most admirable treatise. The author has given us almost a cyclopædia within the limits of a convenient volume, and has done so without penning the *useless* paragraphs too commonly making up a great part of the bulk of many cumbrous works. The progressive scientist is not disappointed when he looks for the record of new and valuable processes and discoveries, while the cautious conservative does not find his pages monopolized by uncertain theories and speculations. A peculiar point of excellence is the crystallized form of expression in which great truths are expressed in very short paragraphs. One is surprised at the brief space allotted to an important topic, and yet, after reading it, he feels that little, if any more should have been said. Altogether, it is seldom you see a text-book so nearly faultless. — *Cincinnati Lancet*, Nov. 1873.

CLOWES (FRANK), D.Sc., London.

Senior Science-Master at the High School, Newcastle-under-Lyme, etc.

AN ELEMENTARY TREATISE ON PRACTICAL CHEMISTRY AND QUALITATIVE INORGANIC ANALYSIS.

Specially adapted for Use in the Laboratories of Schools and Colleges and by Beginners. Second American from the Third and Revised English Edition. In one very handsome royal 12mo. volume of 372 pages, with 47 illustrations. Cloth, $2 50. (*Just Ready.*)

This is a valuable work for those about to commence chemistry, the more so as by its use they are simultaneously acquainted with the manipulation of chemical analysis, a method which is the most valuable to impart a thorough knowledge of chemistry. It is a very good little book, and will make for itself many warm friends and supporters. It treats the subject well and the tables are very clear and valuable.—*St Louis Med. and Surg. Journ.*, Mar. 1881.

This work is not only well adapted for use as a text-book in medical colleges, but is also one of the best that a practitioner can have for convenient reference and instruction in his library. As a rule, such volumes are too technical and abstruse for study without some didactic aid, but the volume presented is easy of comprehension, and will be of great value to college students and busy practitioners.—*N. Y. Am. Med. Bi-Weekly*, April 9, 1881.

The tables particularly demand praise, for they are admirably formed, both for convenience of reference and fulness of information. In short, we do not remember to have met with a book which could better serve the student as a guide to the systematic study of inorganic chemistry.—*Louisville Med. News*, March 12, 1881.

KNAPP'S TECHNOLOGY; or Chemistry Applied to the Arts and to Manufactures. With American additions by Prof. WALTER R. JOHNSON. In two very handsome octavo volumes, with 500 wood engravings, cloth, $6 00.

PARRISH (*EDWARD*),

Late Professor of Materia Medica in the Philadelphia College of Pharmacy.

A TREATISE ON PHARMACY. Designed as a Text-Book for the Student, and as a Guide for the Physician and Pharmaceutist. With many Formulæ and Prescriptions. Fourth Edition, thoroughly revised, by THOMAS S. WIEGAND. In one handsome octavo volume of 977 pages, with 280 illustrations; cloth, $5 50; leather, $6 50; half Russia, $7.

Of Dr. Parrish's great work on pharmacy it only remains to be said that the editor has accomplished his work so well as to maintain, in this fourth edition, the high standard of excellence which it had attained in previous editions, under the editorship of its accomplished author. This has not been accomplished without much labor, and many additions and improvements, involving changes in the arrangement of the several parts of the work, and the addition of much new matter. With the modifications thus effected it constitutes, as now presented, a compendium of the science and art indispensable to the pharmacist, and of the utmost value to every practitioner of medicine desirous of familiarizing himself with the pharmaceutical preparation of the articles which he prescribes for his patients.—*Chicago Med. Journ.*, July, 1874.

The work is eminently practical, and has the rare merit of being readable and interesting, while it preserves a strictly scientific character. The whole work reflects the greatest credit on author, editor and publisher. It will convey some idea of the liberality which has been bestowed upon its production when we mention that there are no less than 280 carefully executed illustrations. In conclusion, we heartily recommend the work, not only to pharmacists, but also to the multitude of medical practitioners who are obliged to compound their own medicines. It will ever hold an honored place on our own bookshelves.—*Dublin Med. Press and Circular*, Aug. 12, 1874.

We expressed our opinion of a former edition in terms of unqualified praise, and we are in no mood to detract from that opinion in reference to the present edition, the preparation of which has fallen into competent hands. It is a book with which no pharmacist can dispense, and from which no physician can fail to derive much information of value to him in practice.—*Pacific Med. and Surg. Journ.*, June, '74.

Perhaps one, if not the most important book upon pharmacy which has appeared in the English language has emanated from the transatlantic press. "Parrish's Pharmacy" is a well-known work on this side of the water, and the fact shows us that a really useful work never becomes merely local in its fame. Thanks to the judicious editing of Mr. Wiegand, the posthumous edition of "Parrish" has been saved to the public with all the mature experience of its author, and perhaps none the worse for a dash of new blood.—*Lond. Pharm. Journal*, Oct. 17, 1874.

GRIFFITH (*ROBERT E.*), *M.D.*

A UNIVERSAL FORMULARY, Containing the Methods of Preparing and Administering Officinal and other Medicines. The whole adapted to Physicians and Pharmaceutists. Third edition, thoroughly revised, with numerous additions, by JOHN M. MAISCH, Professor of Materia Medica in the Philadelphia College of Pharmacy. In one large and handsome octavo volume of about 800 pages. Cloth, $4 50; leather, $5 50.

To the druggist a good formulary is simply indispensable, and perhaps no formulary has been more extensively used than the well-known work before us. Many physicians have to officiate, also, as druggists. This is true especially of the country physician, and a work which shall teach him the means by which to administer or combine his remedies in the most efficacious and pleasant manner, will always hold its place upon his shelf. A formulary of this kind is of benefit also to the city physician in largest practice.—*Cincinnati Clinic*, Feb. 21, 1874.

A more complete formulary than it is in its present form the pharmacist or physician could hardly desire. To the first some such work is indispensable, and it is hardly less essential to the practitioner who compounds his own medicines. Much of what is contained in the introduction ought to be committed to memory by every student of medicine. As a help to physicians it will be found invaluable, and doubtless will make its way into libraries not already supplied with a standard work of the kind.—*The American Practitioner*, Louisville, July, '74.

FARQUHARSON (*ROBERT*), *M.D.*,

Lecturer on Materia Medica at St. Mary's Hospital Medical School.

A GUIDE TO THERAPEUTICS AND MATERIA MEDICA. Second American edition, revised by the Author. Enlarged and adapted to the U. S. Pharmacopœia. By FRANK WOODBURY, M.D. In one neat royal 12mo. volume of 498 pages: cloth, $2.25. (*Lately Issued.*)

The appearance of a new edition of this convenient and handy book in less than two years may certainly be taken as an indication of its usefulness. Its convenient arrangement, and its terseness, and, at the same time, completeness of the information given, make it a handy book of reference.—*Am. Journ of Pharmacy*, June, 1879.

This work contains in moderate compass such well-digested facts concerning the physiological and therapeutical action of remedies as are reasonably established up to the present time. By a convenient arrangement the corresponding effects of each article in health and disease are presented in parallel columns, not only rendering reference easier, but also impressing the facts more strongly upon the mind of the reader. The book has been adapted to the wants of the American student, and copious notes have been introduced, embodying the latest revision of the Pharmacopœia, together with the antidotes to the more prominent poisons, and such of the newer remedial agents as seemed necessary to the completeness of the work. Tables of weights and measures, and a good alphabetical index end the volume.—*Druggists' Circular and Chemical Gazette*, June, 1879.

It is a pleasure to think that the rapidity with which a second edition is demanded may be taken as an indication that the sense of appreciation of the value of reliable information regarding the use of remedies is not entirely overwhelmed in the cultivation of pathological studies, characteristic of the present day. This work certainly merits the success it has so quickly achieved.—*New Remedies*, July, '79.

CHRISTISON'S DISPENSATORY. With copious additions, and 213 large wood engravings. By R. EGLESFIELD GRIFFITH, M.D. One vol. 8vo., pp. 1000, cloth, $4 00.

CARPENTER'S PRIZE ESSAY ON THE USE OF ALCOHOLIC LIQUORS IN HEALTH AND DISEASE. New edition, with a Preface by D. F. CONDIE, M.D., and explanations of scientific words. In one neat 12mo. volume, pp. 178, cloth, 60 cents.

STILLÉ (*ALFRED*), *M.D., LL.D., and* MAISCH (*JOHN M.*), *Ph.D.*,
Prof. of Theory and Practice of Medicine and of Clinical Med. in Univ. of Pa.
Prof. of Mat. Med. and Bot in Phila. Coll. Pharmacy, Secy. to the American Pharmaceutical Association.

THE NATIONAL DISPENSATORY: Containing the Natural History, Chemistry, Pharmacy, Actions and Uses of Medicines, including those recognized in the Pharmacopœias of the United States, Great Britain and Germany, with numerous references to the French Codex. Second edition, thoroughly revised, with numerous additions. In one very handsome octavo volume of 1692 pages, with 239 illustrations. Extra cloth, $6 75; leather, raised bands, $7 50; half Russia, raised bands and open back, $8 25. (*Now Ready.*)

PREFACE TO THE SECOND EDITION.

The demand which has exhausted in a few months an unusually large edition of the National Dispensatory is doubly gratifying to the authors, as showing that they were correct in thinking that the want of such a work was felt by the medical and pharmaceutical professions, and that their efforts to supply that want have been acceptable. This appreciation of their labors has stimulated them in the revision to render the volume more worthy of the very marked favor with which it has been received. The first edition of a work of such magnitude must necessarily be more or less imperfect; and though but little that is new and important has been brought to light in the short interval since its publication, yet the length of time during which it was passing through the press rendered the earlier portions more in arrears than the later. The opportunity for a revision has enabled the authors to scrutinise the work as a whole, and to introduce alterations and additions wherever there has seemed to be occasion for improvement or greater completeness. The principal changes to be noted are the introduction of several drugs under separate headings, and of a large number of drugs, chemicals and pharmaceutical preparations classified as allied drugs and preparations under the heading of more important or better known articles: these additions comprise in part nearly the entire German Pharmacopœia and numerous articles from the French Codex. All new investigations which came to the authors' notice up to the time of publication have received due consideration.

The series of illustrations has undergone a corresponding thorough revision. A number have been added, and still more have been substituted for such as were deemed less satisfactory.

The new matter embraced in the text is equal to nearly one hundred pages of the first edition. Considerable as are these changes as a whole, they have been accommodated by an enlargement of the page without increasing unduly the size of the volume.

While numerous additions have been made to the sections which relate to the physiological action of medicines and their use in the treatment of disease, great care has been taken to make them as concise as was possible without rendering them incomplete or obscure. The doses have been expressed in the terms both of troy weight and of the metrical system, for the purpose of making those who employ the Dispensatory familiar with the latter, and paving the way for its introduction into general use.

The Therapeutical Index has been extended by about 2250 new references, making the total number in the present edition about 6000.

The articles there enumerated as remedies for particular diseases are not only those which, in the authors' opinion, are curative, or even beneficial, but those also which have at any time been employed on the ground of popular belief or professional authority. It is often of as much consequence to be acquainted with the worthlessness of certain medicines or with the narrow limits of their power, as to know the well attested virtues of others and the conditions under which they are displayed. An additional value posse sed by such an Index is, that it contains the elements of a natural classification of medicines, founded upon an analysis of the results of experience, which is the only safe guide in the treatment of disease.

This evidence of success, seldom paralleled, shows clearly how well the authors have met the existing needs of the pharmaceutical and medical professions. Gratifying as it must be to them, they have embraced the opportunity offered for a thorough revision of the whole work, striving to embrace within it all that might have been omitted in the former edition, and all that has newly appeared of sufficient importance during the time of its collaboration, and the short interval elapsed since the previous publication. After having gone carefully through the volume we must admit that the authors have labored faithfully, and with success, in maintaining the high character of their work as a compendium meeting the requirements of the day, to which one can safely turn in quest of the latest information concerning everything worthy of notice in connection with Pharmacy, Materia Medica, and Therapeutics.—*Am. Jour. of Pharmacy*, Nov. 1879.

It is with great pleasure that we announce to our readers the appearance of a *second* edition of the National Dispensatory. The total exhaustion of the first edition in the short space of six months, is a sufficient testimony to the value placed upon the work by the profession. It appears that the rapid sale of the first edition must have induced both the editors and the publisher to make preparations for a new edition immediately after the first had been issued, for we find a large amount of new matter added and a good deal of the previous text altered and improved, which proves that the authors do not intend to let the grass grow under their feet, but to keep the work up to the time.—*New Remedies*, Nov. 1879.

This is a great work by two of the ablest writers on materia medica in America. The authors have produced a work which, for accuracy and comprehensiveness, is unsurpassed by any work on the subject. There is no book in the English language which contains so much valuable information on the various articles of the materia medica. The work has cost the authors years of laborious study, but they have succeeded in producing a dispensatory which is not only *national*, but will be a lasting memorial of the learning and ability of the authors who produced it.—*Edinburgh Medical Journal*, Nov. 1879.

It is by far more international or universal than any other book of the kind in our language, and more comprehensive in every sense.—*Pacific Med. and Surg. Journ.*, Oct. 1879.

The National Dispensatory is beyond dispute the very best authority. It is throughout complete in all the necessary details, clear and lucid in its explanations, and replete with references to the most recent writings, where further particulars can be obtained, if desired. Its value is greatly enhanced by the extensive indices—a general index of materia medica, etc., and also an index of therapeutics. It would be a work of supererogation to say more about this well-known work. No practising physician can afford to be without the National Dispensatory.—*Canada Med. and Surg. Journ.*, Feb. 1880.

MAISCH (JOHN M.), Phar. D.,

Prof. of Materia Medica and Botany in the Phila. Coll. of Pharmacy.

A MANUAL OF ORGANIC MATERIA MEDICA. Being a Guide to Materia Medica of the Vegetable and Animal Kingdoms. For the use of Students, Druggists, Pharmacists and Physicians. In one handsome 12mo. volume, with numerous illustrations on wood. (*Preparing.*)

EXTRACT FROM THE AUTHOR'S PREFACE.

When in 1866 the author was called to the chair of Materia Medica in the institution named (the Philadelphia College of Pharmacy), he seriously felt the need of a suitable text book which could be used in connection with his lectures, and made preparations for the publication of such a work at an early date. To elaborate a system of classification, which should be without difficulty comprehended and readily applied by those for whom it was intended, was by no means an easy task, and the author found occasion, almost every year, to either remodel that previously selected, or to make what in his opinion seemed to be desirable improvements. The publication of the "National Dispensatory" in a measure supplied the want felt, at least as far as a work of reference is concerned, but owing to its local arrangement, it is not adapted to systematic instruction. However, its publication rendered a modification of the original plan for a treatise on Materia Medica desirable, and it is now presented in a form giving an outline of the substance of the lectures and embracing what are considered the essential physical, histological, and chemical characters of the organic drug, so as to render the work also a useful and reliable guide in business transactions. Regarding the classification, the author is conscious of its imperfections, but he believes it to be convenient and capable of practical application.

In reference to the scope of the work, the main aim has been to embrace all the drugs recognized by the U. S. Pharmacopœia, together with the old, but now unofficinal ones, and such others, the use of which has been recently revived or suggested, and which seem to deserve attention. The medical properties and doses of the various drugs are merely briefly stated as subjects of general important information; the present work is not intended for giving instruction in the therapeutic application of drugs.

STILLÉ (ALFRED), M. D.,

Professor of Theory and Practice of Medicine in the University of Penna.

THERAPEUTICS AND MATERIA MEDICA; a Systematic Treatise on the Action and Uses of Medicinal Agents, including their Description and History. Fourth edition, revised and enlarged. In two large and handsome 8vo. vols. of about 2000 pages. Cloth, $10; leather, $12; half Russia, $13.

It is unnecessary to do much more than to announce the appearance of the fourth edition of this well known and excellent work.—*Brit. and For. Med.-Chir. Review*, Oct 1875.

For all who desire a complete work on therapeutics and materia medica for reference, in cases involving medico-legal questions, as well as for information concerning remedial agents, Dr. Stillé's is "*par excellence*" the work. Being out of print, by the exhaustion of former editions, the author has laid the profession under renewed obligations, by the careful revision, important additions, and timely reissuing a work not exactly supplemented by any other in the English language, if in any language. The mechanical execution handsomely sustains the well-known skill and good taste of the publisher.—*St. Louis Med. and Surg. Journal*, Dec 1874.

From the publication of the first edition "Stillé's Therapeutics" has been one of the classics; its absence from our libraries would create a vacuum which could be filled by no other work in the language, and its presence supplies, in the two volumes of the present edition, a whole cyclopædia of therapeutics.—*Chicago Medical Journal*, Feb. 1875.

The rapid exhaustion of three editions and the universal favor with which the work has been received by the medical profession, are sufficient proof of its excellence as a repertory of practical and useful information for the physician. The edition before us fully sustains this verdict, as the work has been carefully revised and in some portions rewritten, bringing it up to the present time by the admission of chloral and croton chloral nitrite of amyl, bichloride of methylene, methylic ether, lithium compounds, gelseminum, and other remedies.—*Am. Journ. of Pharmacy*, Feb. 1875.

We can hardly admit that it has a rival in the multitude of its citations and the fulness of its research into clinical histories, and we must assign it a place in the physician's library; not, indeed, as fully representing the present state of knowledge in pharmacodynamics, but as by far the most complete treatise upon the clinical and practical side of the question.—*Boston Med. and Surg. Journal*, Nov. 5, 1874.

CORNIL (V.), AND RANVIER (L.),

Prof. in the Faculty of Med., Paris. *Prof. in the College of France.*

MANUAL OF PATHOLOGICAL HISTOLOGY. Translated, with Notes and Additions, by E. O. SHAKESPEARE, M.D., Pathologist and Ophthalmic Surgeon to Philada. Hospital, Lecturer on Refraction and Operative Ophthalmic Surgery in Univ. of Penna., and by HENRY C. SIMES, M.D., Demonstrator of Pathological Histology in the Univ. of Pa. In one very handsome octavo volume of over 700 pages, with over 350 illustrations. Cloth, $5 50; leather, $6 50; half Russia, $7. (*Just Ready.*)

We have no hesitation in cordially recommending the English translation of Cornil & Ranvier's "Pathological Histology" as the best work of the kind in any language, and as giving to its readers a trustworthy guide in obtaining a broad and solid basis for the appreciation of the practical bearings of pathological anatomy.—*Am. Journ. of Med. Sciences*, April, 1880.

This important work, in its American dress, is a welcome offering to all students of the subjects which it treats. The great mass of material is arranged naturally and comprehensively. The classification of tumors is clear and full, so far as the subject admits of definition, and this one chapter is worth the price of the book. The illustrations are copious and well chosen. Without the slightest hesitation, the translators deserve honest thanks for placing this indispensable work in the hands of American students.—*Phila. Med. Times*, April 24, 1880.

This volume we cordially commend to the profession. It will prove a valuable, almost necessary, addition to the libraries of students who are to be physicians, and to the libraries of students who are physicians.—*American Practitioner*, June, 1880.

FENWICK (SAMUEL), M.D.,

Assistant Physician to the London Hospital.

THE STUDENT'S GUIDE TO MEDICAL DIAGNOSIS.

From the Third Revised and Enlarged English Edition. With eighty-four illustrations on wood. In one very handsome volume, royal 12mo., cloth, $2 25. (*Lately Issued.*)

GREEN (T. HENRY), M.D.,

Lecturer on Pathology and Morbid Anatomy at Charing-Cross Hospital Medical School, etc.

PATHOLOGY AND MORBID ANATOMY.

Fourth American, from the Fifth Enlarged and Revised English Edition. In one very handsome octavo volume of about 350 pages, with 138 fine engravings; cloth, $2 25. (*Just Ready.*)

EXTRACT FROM THE AUTHOR'S PREFACE.

In preparing the fifth edition of my Text-book on Pathology and Morbid Anatomy, I have again added much new matter, with the object of making the work a more complete guide for the student. All the chapters have been carefully revised, some alterations have been made in the arrangement of the work, and an addition has been made to the number of wood-cuts. The new wood-cuts, as in previous editions, have been drawn by Mr. Collings from my own microscopical preparations.

We have long considered this the best guide yet presented to the student for the identification of various morbid tissues. We have found it more satisfactory than any other. The present edition has been thoroughly revised, and much new matter has been added. To the physician as a guide in diagnosis, we recommend this volume.—*Physician and Surgeon*, May, 1881.

BRISTOWE (JOHN SYER), M.D., F.R.C.P.,

Physician and Joint Lecturer on Medicine, St. Thomas's Hospital.

A TREATISE ON THE PRACTICE OF MEDICINE.

Second American edition, revised by the Author. Edited, with Additions, by JAMES H. HUTCHINSON, M.D., Physician to the Penna. Hospital. In one handsome octavo volume of nearly 1200 pages. With illustrations. Cloth, $5 00; leather, $6 00; half Russia, $6 50. (*Now Ready.*)

The second edition of this excellent work, like the first, has received the benefit of Dr. Hutchinson's annotations, by which the phases of disease which are peculiar to this country are indicated, and thus a treatise which was intended for British practitioners and students is made more practically useful on this side of the water. We see no reason to modify the high opinion previously expressed with regard to Dr. Bristowe's work, except by adding our appreciation of the careful labors of the author in following the lateral growth of medical science.—*Boston Medical and Surgical Journal*, February, 1880

What we said of the first edition, we can, with increased emphasis, repeat concerning this: "Every page is characterized by the utterances of a thoughtful man. What has been said, has been well said, and the book is a fair reflex of all that is *certainly known* on the subjects considered."—*Ohio Med Recorder*, Jan. 7, 1880.

The views of the author are expressed with precision and sufficient promptness to impress the student with the weight of his authority; and should the medical professor differ on any subject from his doctrine, he will need to find strong arguments to carry his class to the opposite conclusion.—*N. O. Med. and Surg. Journ*, Feb. 1880.

The reader will find every conceivable subject connected with the practice of medicine ably presented, in a style at once clear, interesting, and concise. The additions made by Dr. Hutchinson are appropriate and practical, and greatly add to its usefulness to American readers.—*Buffalo Med. and Surg. Journ*, March, 1880.

We regard it as an excellent work for students and for practitioners. It is clearly written, the author's style is attractive, and it is especially to be commended for its excellent exposition of the pathology and clinical phenomena of disease.—*St. Louis Clin. Record*, Feb. 1880.

HABERSHON (S. O.) M.D.

Senior Physician to, and late Lecturer on the Principles and Practice of Medicine at, Guy's Hospital, etc.

ON THE DISEASES OF THE ABDOMEN, COMPRISING THOSE

of the Stomach, and other parts of the Alimentary Canal, Œsophagus, Cæcum, Intestines and Peritoneum. Second American, from the Third enlarged and revised English edition. With illustrations. In one handsome octavo volume of over 500 pages. Cloth, $3 50. (*Lately Issued.*)

This valuable treatise on diseases of the stomach and abdomen has been out of print for several years, and is therefore not so well known to the profession as it deserves to be. It will be found a cyclopædia of information, systematically arranged, on all diseases of the alimentary tract, from the mouth to the rectum. A fair proportion of each chapter is devoted to symptoms, pathology, and therapeutics. The present edition is fuller than former ones in many particulars, and has been thoroughly revised and amended by the author. Several new chapters have been added, bringing the work fully up to the times, and making it a volume of interest to the practitioner in every field of medicine and surgery. Perverted nutrition is in some form associated with all diseases we have to combat, and we need all the light that can be obtained on a subject so broad and general. Dr Habershon's work is one that every practitioner should read and study for himself.—*N. Y. Med. Journ*, April, 1879.

GLUGE'S ATLAS OF PATHOLOGICAL HISTOLOGY. Translated, with Notes and Additions, by JOSEPH LEIDY, M. D. In one volume, very large imperial quarto, with 320 copper-plate figures, plain and colored, cloth. $4 00.

LA ROCHE ON YELLOW FEVER, considered in its Historical, Pathological, Etiological and Therapeutical Relations. In two large and handsome octavo volumes of nearly 1500 pp., cloth. $7 00.

STOKES' LECTURES ON FEVER. Edited by JOHN WILLIAM MOORE, M.D., Assistant Physician to the Cork Street Fever Hospital. In one neat 8vo. volume, cloth, $2 00.

PAVY'S TREATISE ON THE FUNCTION OF DIGESTION: its Disorders and their Treatment. From the Second London edition. In one handsome volume, small octavo, cloth, $2 00.

HOLLAND'S MEDICAL NOTES AND REFLECTIONS. 1 vol 8vo., pp. 500, cloth. $3 50

BARLOW'S MANUAL OF THE PRACTICE OF MEDICINE. With Additions by D. F. CONDIE, M D. 1 vol. 8vo., pp. 600, cloth. $2 50.

TODD'S CLINICAL LECTURES ON CERTAIN ACUTE DISEASES. In one neat octavo volume, of 330 pp. cloth. $2 50.

FLINT (*AUSTIN*), *M.D.*,

Professor of the Principles and Practice of Medicine in Bellevue Med. College, N. Y.

A TREATISE ON THE PRINCIPLES AND PRACTICE OF MEDICINE; designed for the use of Students and Practitioners of Medicine. Fifth edition, entirely rewritten and much improved. In one large and closely printed octavo volume of 1153 pp. Cloth, $5 50; leather, $6 50; very handsome half Russia, raised bands, $7. (*Just Ready.*)

This work has been so long and favorably known, and has obtained so high a position amongst modern treatises on medicine, that it is hardly necessary to do more than announce the publication of this fifth edition. All who peruse it must be struck by the extensive research which has been undertaken in the revision of this edition, combined with much original thought. There is hardly a subject which does not receive fresh illustration and discussion, opening up new lines of inquiry which had not been thought of when the previous edition appeared. We cannot conclude this notice without expressing our admiration of this volume, which is certainly one of the standard text-books on medicine, and we may safely affirm that, taken altogether, it exhibits a fuller and wider acquaintance with recent pathological inquiry than any similar work with which we are acquainted, whilst at the same time it shows its author to be possessed of the rare facilities of clear exposition, thoughtful discrimination, and sound judgment.—*London Lancet*, July 23, 1881.

Practically, this edition is a new work; for so many additions and changes have been made that one well acquainted with previous editions would hardly recognize this as an old friend. The size of the volume is somewhat increased. An entire new section and several new chapters have been added. It is universally conceded that no text book upon this subject was ever published in this country that can at all compare with it. It has long been at the very head of American text book literature, and there can be no doubt but that it will be many years before it yields the place to others.—*Nashville Journ. of Med. and Surg*, Feb. 1881.

"Flint's Practice" is recognized to be a standard treatise of high rank upon the principles and the practice of medicine wherever the English language is read. The opinions everywhere reveal the man of extensive experience, diligent study, calm judgment, and unbiassed criticism. The work should be in the hands of every practitioner.—*New York Med. Record*, Feb. 26, 1881.

The style and character of this work are too well known to the profession to require an introduction. For a number of years this volume has occupied a leading position as a text-book in the majority of medical schools, and the high position accorded to it in the past is a guarantee of a hearty welcome in this new edition. The book may be said to represent the present state of the science of medicine as now understood and taught. It is a safe guide to students and practitioners of medicine.—*Maryland Medical Journal*, March 1, 1881.

The author has, in this edition, revised and rewritten a great part and made it accord with the more advanced ideas which have been developed within the past few years. He is the more fitted to do so, as he is actively engaged in his profession, and can make deductions, not from the work of others, but from his own labors. It is a treatise which every American physician should have upon his table, and which he should consult on occasions when his leisure permits him to do so.—*St. Louis Med and Surg. Journal*, March, 1881.

BY THE SAME AUTHOR.

CLINICAL MEDICINE; a Systematic Treatise on the Diagnosis and Treatment of Diseases. Designed for Students and Practitioners of Medicine. In one large and handsome octavo volume of 795 pages; cloth, $4 50; leather, $5 50; half Russia, $6. (*Now Ready.*)

The eminent teacher who has written the volume under consideration has recognized the needs of the American profession, and the result is all that we could wish. The style in which it is written is peculiarly the author's; it is clear and forcible, and marked by those characteristics which have rendered him one of the best writers and teachers this country has ever produced. We have not space for so full a consideration of this remarkable work as we would desire.—*St. Louis Clin. Record*, Oct. 1879.

It is here that the skill and learning of the great clinician are displayed. He has given us a storehouse of medical knowledge, excellent for the student, convenient for the practitioner, the result of a long life of the most faithful clinical work, collected by an energy as vigilant and systematic as untiring, and weighed by a judgment no less clear than his observation is close.—*Archives of Medicine*, Dec. 1879.

To give an adequate and useful conspectus of the extensive field of modern clinical medicine is a task of no ordinary difficulty; but to accomplish this consistently, with brevity and clearness, the different subjects and their several parts receiving the attention which, relatively to their importance, medical opinion claims for them, is still more difficult. This task we feel bound to say has been executed with more than partial success by Dr Flint, whose name is already familiar to students of advanced medicine in this country as that of the author of two works of great merit on special subjects, and of numerous papers, exhibiting much originality and extensive research.—*The Dublin Journal*, Dec. 1879.

There is every reason to believe that this book will be well received. The active practitioner is frequently in need of some work that will enable him to obtain information in the diagnosis and treatment of cases with comparatively little labor. Dr. Flint has the faculty of expressing himself clearly, and at the same time so concisely as to enable the searcher to traverse the entire ground of his search, and at the same time obtain all that is essential, without plodding through an interminable space.—*N. Y. Med. Jour.*, Nov. 1879.

The great object is to place before the reader the latest observations and experience in diagnosis and treatment. Such a work is especially valuable to students. It is complete in its special design, and yet so condensed, that he can by its aid, keep up with the lectures on practice without neglecting other branches. It will not escape the notice of the practitioner that such a work is most valuable in culling points in diagnosis and treatment in the intervals between the daily rounds of visits, since he can in a few minutes refresh his memory, or learn the latest advance in the treatment of diseases which demand his instant attention.—*Cincinnati Lancet and Clinic*, Oct. 25, 1879.

PREVENTIVE MEDICINE. In one octavo volume of about 500 pages.

(*Shortly.*)

HARTSHORNE (HENRY), M.D.,

Professor of Hygiene in the University of Pennsylvania.

ESSENTIALS OF THE PRINCIPLES AND PRACTICE OF MEDICINE.

A handy book for Students and Practitioners Fifth edition, thoroughly revised and rewritten. With 140 illustrations. In one handsome royal 12mo. volume, of about 600 pages. (*In Press.*)

The very great success which has exhausted four large editions of this work shows that the author has succeeded in supplying a want felt by a large portion of the profession. It has also enabled him in successive revisions to perfect the details of his plan, and to render the work still more worthy of the favor with which it has been received. The present edition has had sedulous attention at the hands of the author to bring it in every way on a level with the most advanced condition of the subject, and no effort has been spared to make the volume worthy a continuance of the very great favor with which it has hitherto been received.

Physician to the German Hospital, Philadelphia, late Chief Assist. to Med. Clinic, Jeff. College Hospital, etc.

A HANDBOOK OF THE PRINCIPLES AND PRACTICE OF Medicine; for the use of Students and Practitioners. In one neat volume, royal 12mo., with illustrations. (*In Press.*)

FOTHERGILL (J. MILNER), M.D. Edin., M.R.C.P. Lond.,

Asst. Phys. to the West Lond. Hosp.; Asst. Phys. to the City of Lond. Hosp., etc.

THE PRACTITIONER'S HANDBOOK OF TREATMENT; Or, the Principles of Therapeutics. Second edition, revised and enlarged. In one very neat octavo volume of about 650 pages. Cloth, $4 00; very handsome half Russia, $5 50. (*Just Ready.*)

The junior members of the profession will find in it a work that should not only be read, but carefully studied. It will assist them in the proper selection and combination of therapeutical agents best adapted to each case and condition, and enable them to prescribe intelligently and successfully. To do full justice to a work of this scope and character will be impossible in a review of this kind. The book itself must be read to be fully appreciated. —*St. Louis Courier of Medicine*, Nov. 1880.

The author merits the thanks of every well-educated physician for his efforts toward rationalizing the treatment of diseases upon the scientific basis of physiology. Every chapter, every line, has the impress of a master hand, and while the work is thoroughly scientific in every particular, it presents to the thoughtful reader all the charms and beauties of a well-written novel. No physician can well afford to be without this valuable work, for its originality makes it fill a niche in medical literature hitherto vacant.—*Nashville Journ. of Med. and Surg.*, Oct. 1880.

Throughout the work, while room is left for difference of opinion in matters of detail, the main courses of treatment are so carefully founded on well-established principles, that no essential difference is felt to be possible The closing chapter contains much concentrated worldly wisdom; and, if carefully read, digested, and assimilated, will, in many an emergency, stand the young medical man in good stead.—*Lond. Med. Record*, Oct. 12, 1880.

FINLAYSON (JAMES), M.D.,

Physician and Lecturer on Clinical Medicine in the Glasgow Western Infirmary, etc.

CLINICAL DIAGNOSIS; A Handbook for Students and Practitioners of Medicine. In one handsome 12mo. volume, of 546 pages, with 85 illustrations. Cloth, $2 63. (*Lately Issued.*)

The book is an excellent one, clear, concise, convenient, practical. It is replete with the very knowledge the student needs when he quits the lecture-room and the laboratory for the ward and sick-room, and does not lack in information that will meet the wants of experienced and older men.—*Phila. Med. Times*, Jan. 4, 1879.

This is one of the really useful books. It is attractive from preface to the final page, and ought to be given a place on every office table, because it contains in a condensed form all that is valuable in semeiology and diagnostics to be found in bulkier volumes, and because in its arrangement and complete index, it is unusually convenient for quick reference in any emergency that may come upon the busy practitioner. —*N. C. Med. Journ.*, Jan. 1879.

WATSON (THOMAS), M.D., &c.

LECTURES ON THE PRINCIPLES AND PRACTICE OF PHYSIC. Delivered at King's College, London. A new American, from the Fifth revised and enlarged English edition. Edited, with additions, and several hundred illustrations, by HENRY HARTSHORNE, M.D., Professor of Hygiene in the University of Pennsylvania. In two large and handsome 8vo. vols. Cloth, $9 00; leather, $11 00.

WILLIAMS'S PULMONARY CONSUMPTION; its Nature, Varieties and Treatment. With an Analysis of One Thousand Cases to exemplify its duration. In one neat octavo volume of about 350 pages; cloth, $2 50.

SLADE ON DIPHTHERIA; its Nature and Treatment, with an account of the History of its Prevalence in various Countries. Second and revised edition. In one neat royal 12mo. volume, cloth, $1 25.

WALSHE ON THE DISEASES OF THE HEART AND GREAT VESSELS. Third American Edition. In 1 vol. 8vo., 420 pp., cloth, $3 00.

SMITH ON CONSUMPTION; ITS EARLY AND REMEDIABLE STAGES 1 vol. 8vo., pp 254 $2 25.

FULLER ON DISEASES OF THE LUNGS AND AIR-PASSAGES. Their Pathology, Physical Diagnosis, Symptoms and Treatment. From the Second and revised English edition. In one handsome octavo volume of about 500 pages: cloth, $3 50.

REYNOLDS (J. RUSSELL), M.D.,

Prof. of the Principles and Practice of Medicine in Univ. College, London.

A SYSTEM OF MEDICINE WITH NOTES AND ADDITIONS BY HENRY HARTSHORNE, M.D., late Professor of Hygiene in the University of Penna. In three large and handsome octavo volumes, containing 3052 closely printed double-columned pages, with numerous illustrations. *Sold only by subscription.* Price per vol., in cloth, $5.00; in sheep, $6.00: half Russia, raised bands, $6.50. Per set in cloth, $15; sheep, $18; half Russia, $19.50

VOLUME I. (*just ready*) contains GENERAL DISEASES and DISEASES OF THE NERVOUS SYSTEM.

VOLUME II. (*just ready*) contains DISEASES OF RESPIRATORY and CIRCULATORY SYSTEMS.

VOLUME III. (*just ready*) contains DISEASES OF THE DIGESTIVE and BLOOD GLANDULAR SYSTEMS, OF THE URINARY ORGANS, OF THE FEMALE REPRODUCTIVE SYSTEM, and OF THE CUTANEOUS SYSTEM.

Reynolds's SYSTEM OF MEDICINE, recently completed, has acquired, since the first appearance of the first volume, the well-deserved reputation of being the work in which modern British medicine is presented in its fullest and most practical form. This could scarce be otherwise in view of the fact that it is the result of the collaboration of the leading minds of the profession, each subject being treated by some gentleman who is regarded as its highest authority—as for instance, Diseases of the Bladder by Sir HENRY THOMPSON, Malpositions of the Uterus by GRAILY HEWITT, Insanity by HENRY MAUDSLEY, Consumption by J. HUGHES BENNET, Diseases of the Spine by CHARLES BLAND RADCLIFFE, Pericarditis by FRANCIS SIBSON, Alcoholism by FRANCIS E. ANSTIE, Renal Affections by WILLIAM ROBERTS, Asthma by HYDE SALTER, Cerebral Affections by H. CHARLTON BASTIAN, Gout and Rheumatism by ALFRED BARING GARROD, Constitutional Syphilis by JONATHAN HUTCHINSON, Diseases of the Stomach by WILSON FOX, Diseases of the Skin by BALMANNO SQUIRE, Affections of the Larynx by MORELL MACKENZIE, Diseases of the Rectum by BLIZARD CURLING, Diabetes by LAUDER BRUNTON, Intestinal Diseases by JOHN SYER BRISTOWE, Catalepsy and Somnambulism by THOMAS KING CHAMBERS, Apoplexy by J. HUGHLINGS JACKSON, Angina Pectoris by Professor GAIRDNER, Emphysema of the Lungs by Sir WILLIAM JENNER, etc etc. All the leading schools in Great Britain have contributed their best men in generous rivalry, to build up this monument of medical science. St. Bartholomew's, Guy's, St Thomas's, University College, St. Mary's, in London, while the Edinburgh, Glasgow, and Manchester schools are equally well represented, the Army Medical School at Netley, the military and naval services, and the public health boards. That a work conceived in such a spirit, and carried out under such auspices should prove an indispensable treasury of facts and experience, suited to the daily wants of the practitioner, was inevitable, and the success which it has enjoyed in England, and the reputation which it has acquired on this side of the Atlantic, have sealed it with the approbation of the two pre-eminently practical nations.

Its large size and high price having kept it beyond the reach of many practitioners in this country who desire to possess it, a demand has arisen for an edition at a price which shall render it accessible to all. To meet this demand the present edition has been undertaken. The five volumes and five thousand pages of the original have by the use of a smaller type and double columns, been compressed into three volumes of over three thousand pages, clearly and handsomely printed, and offered at a price which renders it one of the cheapest works ever presented to the American profession.

But not only is the American edition more convenient and lower priced than the English; it is also better and more complete. Some years having elapsed since the appearance of a portion of the work, additions are required to bring up the subjects to the existing condition of science. Some diseases, also, which are comparatively unimportant in England, require more elaborate treatment to adapt the articles devoted to them to the wants of the American physician; and there are points on which the received practice in this country differs from that adopted abroad. The supplying of these deficiencies has been undertaken by HENRY HARTSHORNE, M.D., late Professor of Hygiene in the University of Pennsylvania, who has endeavored to render the work fully up to the day, and as useful to the American physician as it has proved to be to his English brethren. The number of illustrations has also been largely increased, and no effort spared to render the typographical execution unexceptionable in every respect.

Really too much praise can scarcely be given to this noble book. It is a cyclopædia of medicine written by some of the best men of Europe. It is all of useful information such as one finds frequent need of in one's daily work. As a book of reference it is invaluable. It is up with the times. It is clear and concentrated in style, and its form is worthy of its famous publisher.—*Louisville Med. News*, Jan. 31, 1880.

"Reynolds' System of Medicine" is justly considered the most popular work on the principles and practice of medicine in the English language. The contributors to this work are gentlemen of well-known reputation on both sides of the Atlantic. Each gentleman has striven to make his part of the work as practical as possible, and the information contained is such as is needed by the busy practitioner.—*St. Louis Med. and Surg. Journ.*, Jan. '80.

Dr. Hartshorne has made ample additions and revisions, all of which give increased value to the volume, and render it more useful to the American practitioner. There is no volume in English medical literature more valuable, and every purchaser will, on becoming familiar with it, congratulate himself on the possession of this vast storehouse of information, in regard to so many of the subjects with which he should be familiar.—*Gaillard's Med. Journ.*, Feb. 1880.

There is no medical work which we have in times past more frequently and fully consulted when perplexed by doubts as to treatment, or by having unusual or apparently inexplicable symptoms presented to us than "Reynolds' System of Medicine." Among its contributors are gentlemen who are as well known by reputation upon this side of the Atlantic as in Great Britain, and whose right to speak with authority upon the subjects about which they have written, is recognized the world over. They have evidently striven to make their essays as practical as possible, and while these are sufficiently full to entitle them to the name of monographs, they are not loaded down with such an amount of detail as to render them wearisome to the general reader. In a word, they contain just that kind of information which the busy practitioner frequently finds himself in need of. In order that any deficiencies may be supplied, the publishers have committed the preparation of the book for the press to Dr. Henry Hartshorne, whose judicious notes distributed throughout the volume afford abundant evidence of the thoroughness of the revision to which he has subjected it.—*Am. Jour. Med. Sciences*, Jan. 1880.

BARTHOLOW (ROBERTS), A.M., M.D., LL.D.

Prof. of Materia Medica and General Therapeutics in the Jeff. Med. Coll. of Phila., etc.

A PRACTICAL TREATISE ON ELECTRICITY IN ITS APPLICATION TO MEDICINE.

In one very handsome 8vo. volume of about 270 pages, with 98 illustrations. Cloth, $2 50. (*Just ready.*)

EXTRACT FROM THE AUTHOR'S PREFACE.

I have attempted in the preparation of this work to avoid these errors; to prepare one as simple in statement that a student without previous acquaintance with the subject, may readily master the essentials; so complete as to embrace the whole subject of medical electricity, and so condensed as to be complete in a moderate compass. I have endeavored to keep constantly in view the needs of the two classes for whom the work is prepared—students and practitioners. I have assumed an entire unacquaintance with the elements of the subject as the point of departure—for I am addressing those who have either failed to acquire this preliminary knowledge, or having acquired it, find that after the lapse of years, it has become misty and confused. In the accounts of electrical phenomena I have adhered to the modes of expression with which the medical electrical text-books have made us familiar.

This book, then, must be regarded as the exposition of electricity as a remedial agent, made by a medical practitioner for the use of medical practitioners. No claim is made on the ground of pure science. It is believed, however, that the work makes an adequate presentation of the subject, regarding electricity as a remedial agent—as one of the means employed for the treatment and cure of disease.

So far as we know, the need of a clear, simple, untechnical, reliable, concise, and modern treatise upon the subject of medical electricity is only supplied by the volume under consideration. It is not too much to say that, if availed of, it will render accessible to a vast number of members of the profession a therapeutic agent of the greatest value, but which has heretofore been practically of no use whatever to them.—*Maryland Med. Journal*, June 1, 1881.

We have not yet come across a book that can compare with this in clearness and simplicity of statement. We have for a long time needed a text-book on medical electricity, condensed and yet complete, and this want has been well supplied by the distinguished author. The illustrations are elegant, and the book as a whole is a valuable addition to the collection of any student or practitioner.—*Buffalo Med. and Surg. Journal*, June, 1881.

As a whole, the book must be looked upon as an exposition of electricity for remedial purposes, written by a medical practitioner for the use of medical practitioners. From this standpoint the work is worthy of the careful study of all who desire to investigate this subject for purely practical purposes. This work meets a want of very many students and medical practitioners. We greatly err if it be not gladly welcomed by them. The author, from his long experience as a practitioner, is admirably fitted to perform the task of writing a work of this kind for this special class of men.—*Detroit Lancet*, June, 1881.

This book is expressive of careful research and a nice discrimination in the selection of such matter from that at the author's command as is best adapted for the guidance and instruction of the physician whose interest in electricity is proportionate to its practical bearing on diagnosis and treatment. It is thorough, it is accurate, it is readable, and above all is essentially utilizable, if we may use the word, and renders easy of access to the general practitioner the *modus operandi* of employing this very valuable therapeutic agent.—*N. Y. Medical Gaz.*, June 11, 1881.

MITCHELL (S. WEIR), M.D.,

Phys. to Orthopædic Hospital and the Infirmary for Dis. of the Nervous System, Phila., etc. etc.

LECTURES ON DISEASES OF THE NERVOUS SYSTEM, ESPECIALLY IN WOMEN.

In one very handsome 12mo. volume of about 250 pages, with five lithographic plates. Cloth, $1 75 (*Just Ready.*)

The life-long devotion of the author to the subjects discussed in this volume has rendered it eminently desirable that the results of his labors should be embodied for the benefit of those who may experience the difficulties connected with the treatment of this class of disease. Many of these lectures are fresh studies of hysterical affections; others treat of the modifications his views have undergone in regard to certain forms of treatment, while, throughout the whole work, he has been careful to keep in view the practical lessons of his cases.

It is a record of a number of very remarkable cases, with acute analyses and discussions, clinical, physiological, and therapeutical. It is a book to which the physician meeting with a new hysterical experience, or in doubt whether his new experience is hysterical, may well turn with a well-grounded hope of finding a parallelism; it will be a new experience, indeed, if no similar one is here recorded —*Phila. Med. Times*, June 4, 1881.

The name of the author is sufficient guarantee that these topics are ably and appreciatively discussed; suffice it to say that the principles of treatment, both hygienic and therapeutic, are clearly indicated. The articles being in the form of clinical lectures, abound in illustrative cases, and are much easier reading than a systematic treatise on the same topics.—*College and Clinical Record*, May 15, 1881.

It is needless to say that these lectures are extraordinarily rich in acute observation and sound instruction. The reputation of the author is a guarantee of that, and no reader will be disappointed. Nor can too much be said in praise of the admirable style of his medical writings, and each of these lectures reads with the finished grace of a polished essay. Indeed, the book throughout is so fascinating a one that it could not fail to be read entire by every one who begins its pages. —*Phila. Med. and Surg. Reporter*, May 7, 1881.

The book throughout is not only intensely entertaining, but it contains a large amount of rare and valuable information. Dr Mitchell has recorded not only the results of his most careful observation, but has added to the knowledge of the subjects treated by his original investigation and practical study. The book is one we can commend to all of our readers —*Maryland Med. Journal*, May 1, 1881.

HAMILTON (ALLAN McLANE), M.D.,

Attending Physician at the Hospital for Epileptics and Paralytics, Blackwell's Island, N.Y., and at the Out-Patients' Department of the New York Hospital.

NERVOUS DISEASES; THEIR DESCRIPTION AND TREATMENT.

Second edition, thoroughly revised and rewritten. In one handsome octavo volume of about 600 pages, with numerous illustrations. (*In Press.*)

MORRIS (MALCOLM), M.D.,

Joint Lecturer on Dermatology, St. Mary's Hospital Med. School.

SKIN DISEASES, Including their Definitions, Symptoms, Diagnosis, Prognosis, Morbid Anatomy and Treatment. A Manual for Students and Practitioners.

In one 12mo. volume of over 300 pages. With illustrations. Cloth, $1 75. (*Now Ready.*)

To physicians who would like to know something bout skin diseases, so that when a patient presents imself for relief they can make a correct diagnosis nd prescribe a rational treatment, we unhesitatingly ecommend this little book of Dr. Morris. The affecions of the skin are described in a terse, lucid manner, and their several characteristics so plainly set orth that diagnosis will be easy. The treatment n each case is such as the experience of the most minent dermatologists advise.—*Cincinnati Medical News*, April, 1880.

This is emphatically a learner's book; for we can safely say, so far as our judgment goes, that in the whole range of medical literature of a like scope, here is no book which for clearness of expression nd methodical arrangement is better adapted to romote a rational conception of dermatology, a ranch confessedly difficult and perplexing to the beginner.—*St. Louis Courier of Medicine*, April, 1880.

The author of this manual has evidently a full and intimate acquaintance with the literature of dermatology, and with the most recent developments and appliances of cutaneous medicine. He has produced a plain, practical book, by aid of which, who so chooses may train his eye to the recognition of light but significant differences. The descriptions are neither too vague nor over-refined; the directions for treatment are clear and succinct.—*London Brain*, April, 1880.

The author's task has been well done and has produced one of the best recent works upon the difficult subject of which it treats; there is no work published which gives a better view of the elementary facts and principles of dermatology.—*New Orleans Medical and Surgical Journal*, April, 1880.

FOX (TILBURY), M.D., F.R.C.P., and T. C. FOX, B.A., M.R.C.S.,

Physician to the Department for Skin Diseases, University College Hospital.

EPITOME OF SKIN DISEASES. WITH FORMULÆ. FOR STUDENTS AND PRACTITIONERS.

Second edition, thoroughly revised and greatly enlarged. In one very handsome 12mo. volume of 216 pages. Cloth, $1 38.

FLINT (AUSTIN), M.D.,

Professor of the Principles and Practice of Medicine in Bellevue Hospital Med. College, N. Y.

A MANUAL OF PERCUSSION AND AUSCULTATION; of the Physical Diagnosis of Diseases of the Lungs and Heart, and of Thoracic Aneurism.

Second edition. In one handsome royal 12mo. volume: cloth, $1 63. (*Just Ready.*)

The little work before us has already become a standard one, and has become extensively adopted as a text-book. There is certainly none better. It contains the substance of the lessons which the author has for many years given, in connection with practical instruction in auscultation and percussion, to private classes, composed of medical students and practitioners.—*Cincinnati Med. News*, Feb. 1880.

BY THE SAME AUTHOR.

PHTHISIS: ITS MORBID ANATOMY, ETIOLOGY, SYMPTOMATIC EVENTS AND COMPLICATIONS, FATALITY AND PROGNOSIS, TREATMENT AND PHYSICAL DIAGNOSIS; in a series of Clinical Studies.

By AUSTIN FLINT, M.D., Prof. of the Principles and Practice of Medicine in Bellevue Hospital Med. College, New York. In one handsome octavo volume: $3 50.

BY THE SAME AUTHOR.

A PRACTICAL TREATISE ON THE DIAGNOSIS, PATHOLOGY, AND TREATMENT OF DISEASES OF THE HEART.

Second revised and enlarged edition. In one octavo volume of 550 pages, with a plate, cloth, $4.

BY THE SAME AUTHOR.

A PRACTICAL TREATISE ON THE PHYSICAL EXPLORATION OF THE CHEST AND THE DIAGNOSIS OF DISEASES AFFECTING THE RESPIRATORY ORGANS.

Second and revised edition. In one handsome octavo volume of 595 pages, cloth. $4 50.

BROWN (LENNOX), F.R.C.S. Ed.,

Senior Surgeon to the Central London Throat and Ear Hospital, etc.

THE THROAT AND ITS DISEASES. Second American, from the Second English Edition, thoroughly revised.

With one hundred Typical Illustrations in colors, and fifty wood engravings, designed and executed by the author. In one very handsome imperial octavo volume of over 350 pages. (*Preparing.*)

SEILER (CARL), M.D.,

Lecturer on Laryngoscopy at the Univ. of Penna., Chief of the Throat Dispensary at the Univ. Hospital, Phila., etc.

HANDBOOK OF DIAGNOSIS AND TREATMENT OF DISEASES OF THE THROAT AND NASAL CAVITIES.

In one handsome royal 12mo. volume, of 156 pages, with 35 illustrations; cloth, $1. (*Lately Issued.*)

We most heartily commend this book as showing sound judgment in practice, and perfect familiarity with the literature of the specialty it so ably epitomizes.—*Philada. Med. Times*, July 5, 1879.

A convenient little handbook, clear, concise, and accurate in its method, and admirably fulfilling its purpose of bringing the subject of which it treats within the comprehension of the general practitioner.—*N. C. Med. Jour.*, June, 1879.

CLINICAL OBSERVATIONS ON FUNCTIONAL NERVOUS DISORDERS By C. HANDFIELD JONES M.D., Physician to St. Mary's Hospital, &c. Second American Edition. In one handsome octavo volume of 348 pages, cloth, $3 25.

HILLIER'S HANDBOOK OF SKIN DISEASES, for Students and Practitioners. Second Am Ed. In one royal 12mo. vol. of 358 pp. With illustrations. Cloth, $2 25.

BUMSTEAD (FREEMAN J.), M.D., LL.D.,

Late Professor of Venereal Diseases at the Col. of Phys and Surg., New York, &c.

THE PATHOLOGY AND TREATMENT OF VENEREAL DISEASES.

Including the results of recent investigations upon the subject. Fourth Edition, revised and largely rewritten with the co-operation of R. W. Taylor, M.D., of New York, Prof. of Dermatology in the Univ. of Vt. In one large and handsome octavo volume of 835 pages, with 138 illustrations. Cloth, $4 75; leather, $5 75; half Russia $6 25. (*Now Ready.*)

We have to congratulate our countrymen upon the truly valuable addition which they have made to American literature. The careful estimate of the value of the volume, which we have made, justifies us in declaring that this is the best treatise on venereal diseases in the English language, and we might add, if there is a better in any other tongue we cannot name it; there are certainly no books in which the student or the general practitioner can find such an excellent *résumé* of the literature of any topic, and such practical suggestions regarding the treatment of the various complications of every venereal disease. We take pleasure in repeating that we believe this to be the best treatise on venereal disease in the English language, and we congratulate the authors upon their brilliant addition to American medical literature.—*Chicago Med. Journal and Examiner*, February, 1880.

It is, without exception, the most valuable single work on all branches of the subject of which it treats in any language. The pathology is sound, the work is, at the same time, in the highest degree practical, and the hints that he will get from it for the management of any one case, at all obscure or obstinate, will more than repay him for the outlay.—*Archives of Medicine*, April, 1880.

This now classical work on venereal disease comes to us in its fourth edition rewritten, enlarged, and materially improved in every way. Dr. Taylor, as we had every reason to expect, has performed this part of his work with unusual excellence. We feel that what has been written has done but scanty justice to the merits of this truly great treatise.—*St. Louis Courier of Medicine*, Feb. 1880

We find that we have here practically a new book—that the statement of the title page, as to the fact that it has been largely rewritten, is a sufficiently modest announcement for the important changes in the text. After a thorough examination of the present edition, we can assert confidently that the enormous labor we have described has been here most faithfully and conscientiously performed.—*Amer. Journ. Med. Sci.*, Jan 1880.

It is one of the best general treatises on venereal diseases with which we are acquainted, and is especially to be recommended as a guide to the treatment of syphilis.—*London Practitioner*, March, 1880.

GROSS (SAMUEL W.), A.M., M.D.,

Lecturer on Genito-Urinary and Venereal Diseases in the Jefferson Medical College, Phila.

A PRACTICAL TREATISE ON IMPOTENCE, STERILITY AND ALLIED DISORDERS OF THE MALE SEXUAL ORGANS.

In one very handsome octavo volume of 174 pages, with 16 illustrations. Cloth, $1 50. (*Just Ready.*)

EXTRACT FROM THE AUTHOR'S PREFACE.

"My aim has been to supply, in a compact form, practical and strictly scientific information, especially adapted to the wants of the general practitioner, in regard to a class of common and grave disorders, upon the correction of which so much of human happiness depends. In the chapter on Sterility, the abnormal conditions of the semen and the causes which deprive it of its fecundating properties are fully considered—a portion of the work intended to supplement the subject of sterility in the female. From answers to letters addressed to many of the most prominent writers in this country on gynæcology, I find that, with few exceptions, the woman alone commands attention in unfruitful marriages. The importance of examining the husband before subjecting the wife to operation will be best appreciated when I state that he is, as a rule, at fault in at least one example in every six."

CULLERIER (A.), *Surgeon to the Hôpital du Midi.* and BUMSTEAD (FREEMAN J.), *Professor of Venereal Diseases in the College of Physicians and Surgeons, N. Y.*

AN ATLAS OF VENEREAL DISEASES.

Translated and Edited by FREEMAN J. BUMSTEAD. In one large imperial 4to. volume of 328 pages, double-columns, with 26 plates, containing about 150 figures, beautifully colored, many of them the size of life; strongly bound in cloth. $17 00; also, in five parts, stout wrappers, at $3 per part.

Anticipating a very large sale for this work, it is offered at the very low price of THREE DOLLARS a Part, thus placing it within the reach of all who are interested in this department of practice. Gentlemen desiring early impressions of the plates would do well to order it without delay. A specimen of the plates and text sent free by mail, on receipt of 25 cents.

LEE'S LECTURES ON SYPHILIS AND SOME FORMS OF LOCAL DISEASE AFFECTING PRINCIPALLY THE ORGANS OF GENERATION. In one handsome octavo volume; cloth, $2 25.

CONDIE'S PRACTICAL TREATISE ON THE DISEASES OF CHILDREN. Sixth edition, revised and augmented. In one large octavo volume of nearly 800 closely-printed pages, cloth, $5 25; leather $6 25.

WILSON'S STUDENT'S BOOK OF CUTANEOUS MEDICINE and DISEASES OF THE SKIN. In one very handsome royal 12mo volume. $3 50.

CHAMBERS'S MANUAL OF DIET AND REGIMEN IN HEALTH AND SICKNESS. In one handsome octavo volume. Cloth, $2 75.

BASHAM ON RENAL DISEASES: a Clinical Guide to their Diagnosis and Treatment. With Illustrations. In one 12mo. vol. of 304 pages, cloth, $2 00.

LECTURES ON THE STUDY OF FEVER. By A. HUDSON, M.D., M.R.I.A., Physician to the Meath Hospital. In one vol. 8vo., cloth, $2 50.

A TREATISE ON FEVER. By ROBERT D. LYONS, K.C.C. In one octavo volume of 362 pages, cloth $2 25.

HILL ON SYPHILIS AND LOCAL CONTAGIOUS DISORDERS. In one handsome octavo volume; cloth $3 25.

SMITH'S PRACTICAL TREATISE ON THE WASTING DISEASES OF INFANCY AND CHILDHOOD. Second American, from the Second revised and enlarged English edition. In one handsome octavo volume, cloth, $2 50.

LA ROCHE ON PNEUMONIA. 1 vol. 8vo., cloth, of 500 pages. Price, $3 00.

SMITH (*J. LEWIS*), *M.D.*,

Clinical Professor of Diseases of Children in the Bellevue Hospital Med. College, N. Y.

A COMPLETE PRACTICAL TREATISE ON THE DISEASES OF CHILDREN. Fifth Edition, thoroughly revised and rewritten. In one handsome octavo volume of about 800 pages, with illustrations. (*In Press.*)

The very marked favor with which this work has been received wherever the English language is spoken, has stimulated the author, in the preparation of the Fifth Edition, to spare no pains in the endeavor to render it worthy in every respect of a continuance of professional confidence. Many portions of the volume have been rewritten, and much new matter introduced, but by an earnest effort at condensation, the size of the work will not be materially increased.

KEATING (*JOHN M.*), *M.D.*,

Lecturer on the Diseases of Children at the University of Pennsylvania, etc.

THE MOTHER'S GUIDE IN THE MANAGEMENT AND FEEDING OF INFANTS. In one handsome 12mo. vol. of 118 pages. Cloth, $1 00. (*Now Ready.*)

In the preparation of this volume, it has been the object of the author to provide a work that physicians can safely place in the hands of their patients for the purpose of instructing them as to the care and management of their children throughout the first three years of their life. While there already exist a number of such manuals, there is yet lacking one of native origin, especially adapted to the peculiarities of American climate, modes of living, and the various minor circumstances in which the customs of our country differ from those of the old world. The position occupied by the author as lecturer on Diseases of Children at the Univ. of Penna., is a guarantee of the satisfactory manner in which his labor has been performed.

WEST (*CHARLES*), *M. D.*,

Physician to the Hospital for Sick Children, London, &c.

LECTURES ON THE DISEASES OF INFANCY AND CHILDHOOD. Fifth American from the Sixth revised and enlarged English edition. In one large and handsome octavo volume of 678 pages. Cloth, $4 50; leather, $5 50.

BY THE SAME AUTHOR. (*Lately Issued.*)

ON SOME DISORDERS OF THE NERVOUS SYSTEM IN CHILDHOOD; being the Lumleian Lectures delivered at the Royal College of Physicians of London, in March, 1871. In one volume small 12mo., cloth, $1 00.

BY THE SAME AUTHOR.

LECTURES ON THE DISEASES OF WOMEN. Third American, from the Third London edition. In one neat octavo volume of about 550 pages, cloth, $3 75; leather, $4 75.

SWAYNE (*JOSEPH GRIFFITHS*), *M.D.*,

Physician-Accoucheur to the British General Hospital, &c.

OBSTETRIC APHORISMS FOR THE USE OF STUDENTS COMMENCING MIDWIFERY PRACTICE. Second American, from the Fifth and Revised London Edition with Additions by E. R. HUTCHINS, M.D. With Illustrations. In one neat 12mo. volume. Cloth, $1 25.

CHURCHILL ON THE PUERPERAL FEVER AND OTHER DISEASES PECULIAR TO WOMEN. 1 vol. 8vo., pp. 450, cloth $2 50.

DEWEES'S TREATISE ON THE DISEASES OF FEMALES. With illustrations. Eleventh Edition, with the Author's last improvements and corrections. In one octavo volume of 536 pages, with plates, cloth. $3 00.

MEIGS ON THE NATURE, SIGNS AND TREATMENT OF CHILDBED FEVER 1 vol. 8vo, pp. 365, cloth. $2 00.

ASHWELL'S PRACTICAL TREATISE ON THE DISEASES PECULIAR TO WOMEN. Third American, from the Third and revised London edition. 1 vol. 8vo., pp. 528, cloth. $3 50.

WINCKEL (*F.*),

Professor and Director of the Gynæcological Clinic in the University of Rostock.

A COMPLETE TREATISE ON THE PATHOLOGY AND TREATMENT OF CHILDBED, for Students and Practitioners. Translated, with the consent of the author, from the Second German Edition, by JAMES READ CHADWICK, M.D. In one octavo volume. Cloth, $4 00.

MONTGOMERY'S EXPOSITION OF THE SIGNS AND SYMPTOMS OF PREGNANCY. With two exquisite colored plates, and numerous wood-cuts In 1 vol. 8vo., of nearly 600 pp., cloth, $3 75.

RIGBY'S SYSTEM OF MIDWIFERY. With notes and Additional Illustrations. Second American edition. One volume octavo, cloth, 422 pages, $2 50.

THOMAS (T. GAILLARD), M.D.,

Professor of Obstetrics, &c., in the College of Physicians and Surgeons, N. Y., &c

A PRACTICAL TREATISE ON THE DISEASES OF WOMEN. Fifth

Edition, thoroughly revised and rewritten. In one large and handsome octavo volume of over 800 pages, with 266 illustrations. Cloth, $5; leather, $6; very handsome half Russia, raised bands, $6·50. (*Just Ready.*)

The author has taken advantage of the opportunity afforded by the call for a new edition of this work to render it worthy a continuance of the very remarkable favor with which it has been received. Every portion of the work has been carefully revised, very much of it has been rewritten, and additions and alterations introduced wherever the advance of science and the increased experience of the author have shown them desirable. At the same time special care has been exercised to avoid undue increase in the size of the volume. To accommodate the numerous additions a more condensed but very clear letter has been used, notwithstanding which, the number of pages has been increased by more than fifty. The series of illustrations has been extensively changed; many which seemed to be superfluous have been omitted, and a large number of new and superior drawings have been inserted. In its improved form, therefore, it is hoped that the volume will maintain the character it has acquired of a standard authority on every detail of its important subject.

An examination of the work will satisfy that it is one of great merit. It is not a mere compilation from other works, but is the fruit of the ripe thought, sound judgment, and critical observations of a learned, scientific man. It is a treasury of knowledge of the department of medicine to which it is devoted. In its present revised state it certainly holds a foremost position as a gynæcological work, and will continue to be regarded as a standard authority.—*Cincinnati Med. News*, Dec. 1880.

This work needs no introduction to any of the civilized nations of the world. The edition before us adds to the strength of former volumes. With the wisdom of a master teacher he here gives the results that, in his judgment, are most trustworthy at the present time. In its own place it has no rival, because the author is the best teacher on this subject to the masses of the profession. As hitherto this work will be the text-book on diseases of women. We only wish that in other branches of medicine as capable teachers could be found to write our text-books.—*Detroit Lancet*, Jan. 1881.

Since its first appearance, twelve years ago, until the present day, it has held a position of high regard, and is generally conceded to be one of the most practical and trustworthy volumes yet presented to the physician and student in the department of gynæcology. The work embodies not only its author's large experience, but reflects his careful study among other authorities in this branch, both at home and abroad. Dr. Thomas is an able and conscientious teacher. His writings convey his meaning in the same practical and instructive manner. The last edition of this work is fresh from his pen, with decided changes and improvements over former editions. His book presents generally accepted facts, and as a guide to the student is more useful and reliable than any work in the language on diseases of women. This last edition will add new laurels to those already won.—*Md. Med. Journ.*, Nov. 15, 1880.

It has been enlarged and carefully revised. The author has brought it fully abreast with the times, and as the wave of gynæcological progression has been widespread and rapid during the twelve years that have elapsed since the issue of the first edition, one can conceive of the great improvement this edition must be upon the earlier. It is a condensed encyclopædia of gynæcological medicine. The style of arrangement, the masterly manner in which each subject is treated, and the honest convictions derived from probably the largest clinical experience in that specialty of any in this country, all serve to commend it in the highest terms to the practitioner.—*Nashville Journ. of Med. and Surg.*, Jan. 1881.

BARNES (ROBERT), M.D., F.R.C.P.,

Obstetric Physician to St. Thomas's Hospital, &c.

A CLINICAL EXPOSITION OF THE MEDICAL AND SURGICAL DISEASES OF WOMEN.

Second American, from the Second Enlarged and Revised English Edition. In one handsome octavo volume, of 784 pages, with 181 illustrations. Cloth, $4 50; leather, $5 50; half Russia, $6. (*Lately Issued.*)

Dr Barnes stands at the head of his profession in the old country, and it requires but scant scrutiny of his book to show that it has been sketched by a master. It is plain, practical common sense; shows very deep research without being pedantic; is eminently calculated to inspire enthusiasm without inculcating rashness; points out the dangers to be avoided as well as the success to be achieved in the various operations connected with this branch of medicine; and will do much to smooth the rugged path of the young gynæcologist and relieve the perplexity of the man of mature years.—*Canadian Journ. of Med. Science*, Nov. 1878.

We pity the doctor who, having any considerable practice in diseases of women, has no copy of "Barnes" for daily consultation and instruction. It is at once a book of great learning, research, and individual experience, and at the same time eminently practical. That it has been appreciated by the profession, both in Great Britain and in this country, is shown by the second edition following so soon upon the first.—*Am. Practitioner*, Nov. 1878.

Dr. Barnes's work is one of a practical character, largely illustrated from cases in his own experience, but by no means confined to such, as will be learned from the fact that he quotes from no less than 625 medical authors in numerous countries. Coming from such an author, it is not necessary to say that the work is a valuable one, and should be largely consulted by the profession.—*Am. Supp. Obstetrical Journ. Gt. Britain and Ireland*, Oct. 1878.

No other gynæcological work holds a higher position, having become an authority everywhere in diseases of women. The work has been brought fully abreast of present knowledge. Every practitioner of medicine should have it upon the shelves of his library, and the student will find it a superior text-book.—*Cincinnati Med. News*, Oct. 1878.

HODGE (HUGH L.), M.D.,

Emeritus Professor of Obstetrics, &c., in the University of Pennsylvania.

ON DISEASES PECULIAR TO WOMEN; including Displacements

of the Uterus. With original illustrations. Second edition, revised and enlarged. In one beautifully printed octavo volume of 531 pages, cloth, $4 50.

EMMET (*THOMAS ADDIS*). *M.D.*,

Surgeon to the Woman's Hospital, New York, etc.

THE PRINCIPLES AND PRACTICE OF GYNÆCOLOGY, for the use of Students and Practitioners of Medicine. Second Edition. Thoroughly Revised. In one large and very handsome octavo volume of 875 pages, with 133 illustrations. Cloth, $5; leather, $6; half Russia, raised bands, $6 50. (*Just Ready.*)

PREFACE TO THE SECOND EDITION.

The unusually rapid exhaustion of a large edition of this work, while flattering to the author as an evidence that his labors have proved acceptable, has in a great measure heightened his sense of responsibility. He has therefore endeavored to take full advantage of the opportunity afforded to him for its revision. Every page has received his earnest scrutiny; the criticisms of his reviewers have been carefully weighed; and while no marked increase has been made in the size of the volume, several portions have been rewritten, and much new matter has been added. In this minute and thorough revision, the labor involved has been much greater than is perhaps apparent in the results, but it has been cheerfully expended in the hope of rendering the work more worthy of the favor which has been accorded to it by the profession.

In no country of the world has gynæcology received more attention than in America. It is, then, with a feeling of pleasure that we welcome a work on diseases of women from so eminent a gynæcologist as Dr. Emmet, and the work is essentially clinical, and leaves a strong impress of the author's individuality. To criticise, with the care it merits, the book throughout, would demand far more space than is at our command. In parting, we can say that the work teems with original ideas, fresh and valuable methods of practice, and is written in a clear and elegant style, worthy of the literary reputation of the country of Longfellow and Oliver Wendell Holmes.—*Brit. Med. Journ.* Feb 21, 1880.

No gynæcological treatise has appeared which contains an equal amount of original and useful matter; nor does the medical and surgical history of America include a book more novel and useful. The tabular and statistical information which it contains is marvellous, both in quantity and accuracy, and cannot be otherwise than invaluable to future investigators. It is a work which demands not careless reading but profound study. Its value as a contribution to gynæcology is, perhaps, greater than that of all previous literature on the subject combined.—*Chicago Med. Gaz.*, April 5, 1880

The wide reputation of the author makes its publication an event in the gynæcological world; and a glance through its pages shows that it is a work to be studied with care. . . . It must always be a work to be carefully studied and frequently consulted by those who practise this branch of our profession.—*Lond. Med. Times and Gaz.*, Jan. 10, 1880.

The character of the work is too well known to require extended notice—suffice it to say that no recent work upon any subject has attained such great popularity so rapidly. As a work of general reference upon the subject of Diseases of Women it is invaluable. As a record of the largest clinical experience and observation it has no equal. No physician who pretends to keep up with the advances of this department of medicine can afford to be without it.—*Nashville Journ. of Medicine and Surgery*, May, 1880.

DUNCAN (*J. MATTHEWS*), *M.D., LL.D., F.R.S.E., etc.*

CLINICAL LECTURES ON THE DISEASES OF WOMEN, Delivered in Saint Bartholomew's Hospital. In one very neat octavo volume of 173 pages. Cloth, $1 50. (*Just Ready.*)

They are in every way worthy of their author; indeed, we look upon them as among the most valuable of his contributions. They are all upon matters of great interest to the general practitioner. Some of them deal with subjects that are not, as a rule, adequately handled in the text-books; others of them, while bearing upon topics that are usually treated of at length in such works, yet bear such a stamp of individuality that, if widely read, as they certainly deserve to be, they cannot fail to exert a wholesome restraint upon the undue eagerness with which many young physicians seem bent upon following the wild teachings which so infest the gynæcology of the present day.—*N. Y. Med. Journ.*, March, 1880.

The author is a remarkably clear lecturer, and his discussion of symptoms and treatment is full and suggestive. It will be a work which will not fail to be read with benefit by practitioners as well as by students.—*Phila. Med. and Surg. Reporter*, Feb. 7, 1880.

We have read this book with a great deal of pleasure. It is full of good things. The hints on pathology and treatment scattered through the book are sound, trustworthy, and of great value. A healthy scepticism, a large experience, and a clear judgment are everywhere manifest. Instead of bristling with advice of doubtful value and unsound character, the book is in every respect a safe guide.—*The London Lancet*, Jan. 21, 1880.

RAMSBOTHAM (*FRANCIS H.*), *M.D.*

THE PRINCIPLES AND PRACTICE OF OBSTETRIC MEDICINE AND SURGERY, in reference to the Process of Parturition. A new and enlarged edition, thoroughly revised by the author. With additions by W. V. KEATING, M. D., Professor of Obstetrics, &c., in the Jefferson Medical College, Philadelphia. In one large and handsome imperial octavo volume of 650 pages, strongly bound in leather, with raised bands; with sixty-four beautiful plates, and numerous wood-cuts in the text, containing in all nearly 200 large and beautiful figures. $7 00

PARRY (*JOHN S.*), *M.D.*,

Obstetrician to the Philadelphia Hospital, Vice-Pres't of the Obstet. Society of Philadelphia.

EXTRA-UTERINE PREGNANCY: ITS CLINICAL HISTORY, DIAGNOSIS, PROGNOSIS AND TREATMENT. In one handsome octavo volume. Cloth, $2 50.

TANNER (*THOMAS H.*), *M.D.*

ON THE SIGNS AND DISEASES OF PREGNANCY. First American from the Second and Enlarged English Edition. With four colored plates and illustrations on wood. In one handsome octavo volume of about 500 pages, cloth, $4 25.

LEISHMAN (*WILLIAM*), *M.D.*,

Regius Professor of Midwifery in the University of Glasgow, &c.

A SYSTEM OF MIDWIFERY, INCLUDING THE DISEASES OF PREGNANCY AND THE PUERPERAL STATE.

Third American edition, revised by the Author, with additions by JOHN S. PARRY, M.D., Obstetrician to the Philadelphia Hospital, &c. In one large and very handsome octavo volume, of 733 pages, with over two hundred illustrations. Cloth, $4 50; leather, $5 50; half Russia, $6. (*Just Ready*)

Few works on this subject have met with as great a demand as this one appears to have. To judge by the frequency with which its author's views are quoted, and its statements referred to in obstetrical literature, one would judge that there are few physicians devoting much attention to obstetrics who are without it. The author is evidently a man of ripe experience and conservative views, and in no branch of medicine are these more valuable than in this.—*New Remedies*, Jan. 1880.

We gladly welcome the new edition of this excellent text-book of midwifery. The former editions have been most favorably received by the profession on both sides of the Atlantic. In the preparation of the present edition the author has made such alterations as the progress of obstetrical science seems to require, and we cannot but admire the ability with which the task has been performed. We consider it an admirable text-book for students during their attendance upon lectures, and have great pleasure in recommending it. As an exponent of the midwifery of the present day it has no superior in the English language.—*Canada Lancet*, Jan. 1880.

To the American student the work before us must prove admirably adapted, complete in all its parts, essentially modern in its teachings and with demonstrations noted for clearness and precision, it will gain in favor and be recognized as a work of standard merit. The work cannot fail to be popular, and is cordially recommended.—*N. O. Med. and Surg. Journ.*, March, 1880.

PLAYFAIR (*W. S.*), *M.D., F.R.C.P.*,

Professor of Obstetric Medicine in King's College, etc. etc.

A TREATISE ON THE SCIENCE AND PRACTICE OF MIDWIFERY.

Third American edition, revised by the author. Edited, with additions, by ROBERT P. HARRIS, M.D. In one handsome octavo volume of about 700 pages, with nearly 200 illustrations. Cloth, $4; leather, $5; half Russia, $5 50. (*Just Ready.*)

The medical profession has now the opportunity of adding to their stock of standard medical works one of the best volumes on midwifery ever published. The subject is taken up with a master hand. The part devoted to labor in all its various presentations, the management and results, is admirably arranged, and the views entertained will be found essentially modern, and the opinions expressed trustworthy. The work abounds with plates, illustrating various obstetrical positions; they are admirably wrought, and afford great assistance to the student.—*N. O. Med. and Surg. Journ.*, March, 1880.

If inquired of by a medical student what work on obstetrics we should recommend for him, as *par excellence*, we would undoubtedly advise him to choose Playfair's. It is of convenient size, but what is of chief importance, its treatment of the various subjects is concise and plain. While the discussions and descriptions are sufficiently elaborate to render a very intelligent idea of them, yet all details not necessary for a full understanding of the subject are omitted.—*Cincinnati Med. News*, Jan. 1880.

The rapidity with which one edition of this work follows another is proof alike of its excellence and of the estimate that the profession has formed of it. It is indeed so well known and so highly valued that nothing need be said of it as a whole. All things considered, we regard this treatise as the very best on Midwifery in the English language.—*N. Y. Medical Journal*, May, 1880.

It certainly is an admirable exposition of the Science and Practice of Midwifery. Of course the additions made by the American editor, Dr. R. P. Harris, who never utters an idle word, and whose studious researches in some special departments of obstetrics are so well known to the profession, are of great value.—*The American Practitioner*, April, 1880.

BARNES (*FANCOURT*), *M.D.*,

Physician to the General Lying-in Hospital, London.

A MANUAL OF MIDWIFERY FOR MIDWIVES AND MEDICAL STUDENTS.

With 50 illustrations. In one neat royal 12mo. volume of 200 pages; cloth, $1 25. (*Now Ready.*)

PARVIN (*THEOPHILUS*), *M.D.*,

Prof. of Obstetrics and of the Med. and Surg. Diseases of Women in the Med. Coll. of Indiana.

A TREATISE ON MIDWIFERY.

In one very handsome octavo volume of about 550 pages, with numerous illustrations. (*Preparing.*)

HODGE (*HUGH L.*), *M.D.*,

Emeritus Professor of Midwifery, &c., in the University of Pennsylvania, &c.

THE PRINCIPLES AND PRACTICE OF OBSTETRICS.

Illustrated with large lithographic plates containing one hundred and fifty-nine figures from original photographs, and with numerous wood-cuts. In one large and beautifully printed quarto volume of 550 double-columned pages, strongly bound in cloth, $14.

The work of Dr. Hodge is something more than a simple presentation of his particular views in the department of Obstetrics; it is something more than an ordinary treatise on midwifery; it is, in fact, a cyclopædia of midwifery. He has aimed to embody in a single volume the whole science and art of Obstetrics. An elaborate text is combined with accurate and varied pictorial illustrations, so that no fact or principle is left unstated or unexplained. —*Am. Med. Times*, Sept. 8, 1864.

*** Specimens of the plates and letter-press will be forwarded to any address, free by mail, on receipt of six cents in postage stamps.

CHADWICK (*JAMES R.*), *A.M., M.D.*

A MANUAL OF THE DISEASES PECULIAR TO WOMEN.

In one neat volume, royal 12mo., with illustrations. (*Preparing.*)

HAMILTON (FRANK H.) M.D., LL.D.,

Surgeon to the Bellevue Hospital, New York.

A PRACTICAL TREATISE ON FRACTURES AND DISLOCATIONS

Sixth Edition, thoroughly revised, and much improved. In one very handsome octavo volume of over 900 pages, with 352 illustrations. Cloth, $5 50; leather, $6 50; half Russia, raised bands, $7 00. (*Just Ready.*)

So many kind expressions of welcome have been showered upon each successive edition of this valuable treatise, that scarcely anything remains for us to do but to exceed the customary cordial greeting. It is the only complete work on the subject of Fractures in the English language We congratulate the accomplished author on the deserved success of his work, and hope that he may live to have many succeeding editions pass under his skilled supervision.—*Phila. Coll. and Clin. Record*, Nov 15, 1880.

Universal verdict has pronounced it, humanly speaking, a perfect treatise upon this subject. As it is the only complete and illustrated work in any language treating of fractures and dislocations, it is safe to affirm that every wide-awake surgeon and general practitioner will regard it as indispensable to the safe and pleasant conduct of their professional work.—*Detroit Lancet*, Nov. 18, 1880.

Dr Hamilton has devoted great labor to the study of these subjects. His large experience, extended research, and patient investigation have made him one of the highest authorities among living writers in this branch of surgery This work is systematic and practical in its arrangement and presents its subject matter clearly and forcibly to the reader or student.—*Maryland Medical Journal*, Nov. 15, 1880.

The only complete work on its subject in the English tongue, and, indeed, may now be said to be the only work of its kind in any tongue. It would require an exceedingly critical examination to detect in it any particulars in which it might be improved. The work is a monument to American surgery, and will long serve to keep green the memory of its venerable author.—*Michigan Med. News*, Nov. 10, 1851.

ASHHURST (JOHN, Jr.), M.D.,

Prof. of Clinical Surgery, Univ. of Pa., Surgeon to the Episcopal Hospital, Philadelphia.

THE PRINCIPLES AND PRACTICE OF SURGERY.

Second Edition, enlarged and revised. In one very large and handsome octavo volume of over 1000 pages, with 542 illustrations. Cloth, $6; leather, $7; half Russia, $7 50. (*Just Issued.*)

Conscientiousness and thoroughness are two very marked traits of character in the author of this book. Out of these traits largely has grown the success of his mental fruit in the past, and the present offer seems in no wise an exception to what has gone before. The general arrangement of the volume is the same as in the first edition, but every part has been carefully revised, and much new matter added.—*Phila. Med. Times*, Feb. 1, 1879.

The favorable reception of the first edition is a guarantee of the popularity of this edition, which is issued from the editor's hands with many enlargements and improvements. The author of this work is deservedly popular as an editor and writer, and his contributions to the literature of surgery have gained for him wide reputation. The volume now offered the profession will add new laurels to those already won by previous contributions. We can only add that the work is well arranged, filled with practical matter, and contains in brief and clear language all that is necessary to be learned by the student of surgery whilst in attendance upon lectures, or the general practitioner in his daily routine practice.—*Md. Med. Journal*, Jan. 1879.

The fact that this work has reached a second edition so very soon after the publication of the first one, speaks more highly of its merits than anything we might say in the way of commendation. It seems to have immediately gained the favor of students and physicians.—*Cincin. Med. News*, Jan. '79.

We have previously spoken of Dr. Ashhurst's work in terms of praise. We wish to reiterate those terms here, and to add that no more satisfactory representation of modern surgery has yet fallen from the press. In point of judicial fairness, of power of condensation, of accuracy and conciseness of expression and thoroughly good English, Prof. Ashhurst has no superior among the surgical writers in America.—*Am. Practitioner*, Jan. 1879.

STIMSON (LEWIS A.), A.M., M.D.,

Surgeon to the Presbyterian Hospital.

A MANUAL OF OPERATIVE SURGERY.

In one very handsome royal 12mo. volume of about 500 pages, with 332 illustrations; cloth, $2 50.

The work before us is a well printed, profusely illustrated manual of over four hundred and seventy pages. The novice, by a perusal of the work, will gain a good idea of the general domain of operative surgery, while the practical surgeon has presented to him within a very concise and intelligible form the latest and most approved selections of operative procedure. The precision and conciseness with which the different operations are described enable the author to compress an immense amount of practical information in a very small compass.—*N. Y. Medical Record*, Aug. 3, 1878.

This volume is devoted entirely to operative surgery, and is intended to familiarize the student with the details of operations and the different modes of performing them. The work is handsomely illustrated, and the descriptions are clear and well drawn. It is a clever and useful volume; every student should possess one. The preparation of this work does away with the necessity of pondering over larger works on surgery for descriptions of operations, as it presents in a nut-shell just what is wanted by the surgeon without an elaborate search to find it.—*Md. Med Journal*, Aug. 1878.

The author's conciseness and the repleteness of the work with valuable illustrations entitle it to be classed with the text-books for students of operative surgery, and as one of reference to the practitioner. —*Cincinnati Lancet and Clinic*, July 27, 1878.

KEY'S OPERATIVE SURGERY. In 1 vol. 8vo. cl., of 650 pages; with about 100 wood-cuts. $3 25.

COOPER'S LECTURES ON THE PRINCIPLES AND PRACTICE OF SURGERY. In 1 vol. 8vo. cl'h, 750 p. $2.

DIXON'S INSTITUTES AND PRACTICE OF SURGERY. Eighth edit'n, improved and altered. With thirty-four plates. In two handsome octavo volumes, about 1000 pp., leather, raised bands. $6 50.

HEPBURN'S PRINCIPLES AND PRACTICE OF SURGERY. By WILLIAM PIRRIE, F.R.S.E., Professor of Surgery in the University of Aberdeen. Edited by JOHN NEILL, M.D., Professor of Surgery in the Penna. Medical College, Surg'n to the Pennsylvania Hospital, &c. In one very handsome octavo vol. of 780 pages, with 316 illustrations, cloth, $3 75.

MILLER'S PRINCIPLES OF SURGERY. Fourth American, from the Third Edinburgh Edition. In one large 8vo. vol. of 700 pages, with 340 illustrations, cloth, $3 75.

MILLER'S PRACTICE OF SURGERY. Fourth American, from the last Edinburgh Edition Revised by the American editor. In one large 8vo. vol. of nearly 700 pages, with 364 illustrations: cloth, $3 75.

GROSS (*SAMUEL D.*), *M.D.*,

Professor of Surgery in the Jefferson Medical College of Philadelphia.

A SYSTEM OF SURGERY: Pathological, Diagnostic, Therapeutic and Operative. Illustrated by upwards of Fourteen Hundred Engravings. Fifth edition, carefully revised and improved. In two large and beautifully printed imperial octavo volumes of about 2300 pp., strongly bound in leather, with raised bands, $15; half Russia, raised bands, $16.

We have seldom read a work with the practical value of which we have been more impressed. Every chapter is so concisely put together, that the busy practitioner, when in difficulty, can at once find the information he requires. His work is cosmopolitan, the surgery of the world being fully represented in it. The work, in fact, is so historically unprejudiced, and so eminently practical, that it is almost a false compliment to say that we believe it to be destined to occupy a foremost place as a work of reference, while a system of surgery like the present system of surgery is the practice of surgeons. The printing and binding of the work is unexceptionable; indeed, it contrasts, in the latter respect, remarkably with English medical and surgical cloth-bound publications, which are generally so wretchedly stitched as to require re-binding before they are any time in use.—*Dub. Journ. of Med. Sci.*, March, 1874.

Dr. Gross's Surgery, a great work, has become still greater, both in size and merit, in its most recent form. The difference in actual number of pages is not more than 130, but, the size of the page having been increased to what we believe is technically termed "elephant," there has been room for considerable additions, which, together with the alterations, are improvements.—*Lond. Lancet*, Nov. 16, 1872.

It combines, as perfectly as possible, the qualities of a text-book and work of reference. We think this last edition of Gross's "Surgery," will confirm his title of "*Primus inter Pares*." It is learned, scholar-like, methodical, precise, and exhaustive. We scarcely think any living man could write so complete and faultless a treatise, or comprehend more solid, instructive matter in the given number of pages. The labor must have been immense, and the work gives evidence of great powers of mind, and the highest order of intellectual discipline and methodical disposition and arrangement of acquired knowledge and personal experience.—*N.Y. Med. Journ.*, Feb 1873.

As a whole, we regard the work as the representative "System of Surgery" in the English language.—*St. Louis Medical and Surg. Journ.*, Oct. 1872.

The two magnificent volumes before us afford a very complete view of the surgical knowledge of the day. Some years ago we had the pleasure of presenting the first edition of Gross's Surgery to the profession as a work of unrivalled excellence; and now we have the result of years of experience, labor, and study, all condensed upon the great work before us. And to students or practitioners desirous of enriching their library with a treasure of reference, we can simply commend the purchase of these two volumes of immense research.—*Cincinnati Lancet and Observer*, Sept. 1872.

A complete system of surgery—not a mere text-book of operations, but a scientific account of surgical theory and practice in all its departments.—*Brit. and For. Med. Chir. Rev.*, Jan. 1873.

BY THE SAME AUTHOR.

A PRACTICAL TREATISE ON THE DISEASES, INJURIES and Malformations of the Urinary Bladder, the Prostate Gland and the Urethra. Third Edition, thoroughly Revised and Condensed, by SAMUEL W. GROSS, M.D., Surgeon to the Philadelphia Hospital. In one handsome octavo volume of 574 pages, with 170 Illustrations: cloth, $4 50.

For reference and general information, the physician or surgeon can find no work that meets their necessities more thoroughly than this, a revised edition of an excellent treatise, and no medical library should be without it. Replete with handsome illustrations and good ideas, it has the unusual advantage of being easily comprehended, by the reasonable and practical manner in which the various subjects are systematized and arranged. We heartily recommend it to the profession as a valuable addition to the important literature of diseases of the urinary organs.—*Atlanta Med. Journ.*, Oct. 1876.

It is with pleasure we now again take up this standard work in a decidedly new dress. Indeed, it must be regarded as a new book in very many of its parts. The chapters on "Diseases of the Bladder," "Prostate Body," and "Lithotomy," are splendid specimens of descriptive writing; while the chapter on "Stricture" is one of the most concise and clear that we have ever read.—*New York Med. Journ.*, Nov. 1876.

BY THE SAME AUTHOR.

A PRACTICAL TREATISE ON FOREIGN BODIES IN THE AIR-PASSAGES. In 1 vol. 8vo., with illustrations, pp. 468, cloth, $2 75.

DRUITT (*ROBERT*), *M.R.C.S., &c.*

THE PRINCIPLES AND PRACTICE OF MODERN SURGERY. A new and revised American, from the Eighth enlarged and improved London edition. Illustrated with four hundred and thirty-two wood engravings. In one very handsome octavo volume, of nearly 700 large and closely printed pages, cloth, $4 00; leather, $5 00.

All that the surgical student or practitioner could desire.—*Dublin Quarterly Journal.*

It is a most admirable book. We do not know when we have examined one with more pleasure.—*Boston Med. and Surg. Journal.*

In Mr. Druitt's book, though containing only some seven hundred pages, both the principles and the practice of surgery are treated, and so clearly and perspicuously, as to elucidate every important topic. We have examined the book most thoroughly, and can say that this success is well merited. He has, moreover, possesses the inestimable advantage of having the subjects perfectly well arranged and classified and of being written in a style at once clear and succinct.—*Am. Journal of Med. Science.*

ASHTON ON THE DISEASES, INJURIES, AND MALFORMATIONS OF THE RECTUM AND ANUS: with remarks on Habitual Constipation. Second American, from the Fourth and enlarged London Edition. With illustrations. In one 8vo. vol. of 287 pages, cloth, $3 25.

SARGENT ON BANDAGING AND OTHER OPERATIONS OF MINOR SURGERY. New edition, with an additional chapter on Military Surgery. One 12mo. vol. of 383 pages with 184 wood-cuts. Cloth, $1 75.

HOLMES (TIMOTHY), M. A.,

Surgeon and Lecturer on Surgery at St. George's Hospital, London.

A SYSTEM OF SURGERY; THEORETICAL AND PRACTICAL.

IN TREATISES BY VARIOUS AUTHORS. AMERICAN EDITION, THOROUGHLY REVISED AND REWRITTEN by JOHN H. PACKARD, M.D., Surgeon to the Episcopal and St. Joseph's Hospitals, Philadelphia, assisted by a large corps of the most eminent American surgeons. In three large and very handsome imperial octavo volumes of about 1000 pages each, with over 1000 illustrations on wood and thirteen lithographic plates, beautifully colored. (*Sold only by subscription.*) Price per volume, in cloth, $6 00; in leather, $7 00; in half Russia, $7 50. Per set, in cloth, $18 00; in leather, $21 00; in half Russia, $22 50.

VOLUME I. (*now ready*) contains GENERAL PATHOLOGY, MORBID PROCESSES, INJURIES IN GENERAL, COMPLICATIONS OF INJURIES AND INJURIES OF REGIONS.

VOLUME II. (*shortly*) contains DISEASES OF ORGANS OF SPECIAL SENSE, CIRCULATORY SYSTEM, DIGESTIVE TRACT AND GENITO-URINARY ORGANS.

VOLUME III. (*shortly*) contains DISEASES OF THE RESPIRATORY ORGANS, JOINTS, BONES, AND MUSCLES, OPERATIVE AND MINOR SURGERY, GUNSHOT WOUNDS, HOSPITALS AND MISCELLANEOUS SUBJECTS.

This great work, issued some years since in England, has won such universal confidence wherever the language is spoken, that its republication here, in a form more thoroughly adapted to the wants of the American practitioner, has seemed to be a duty owing to the profession.

To accomplish this, the aid has been invited of thirty-three of the most distinguished gentlemen, in every part of the country, and for more than a year they have been assiduously engaged upon the task. Though the original work presents the combined labor of the most eminent members of all the most prominent schools of England, yet the lapse of time since the appearance of the last edition, the progress of science, and the peculiarities of American practice, have rendered necessary a most careful, thorough, and searching revision. Each article has been placed in the hands of a gentleman specially competent to treat its subject, and no labor has been spared to bring each one up to the foremost level of the times, and to adapt it thoroughly to the practice of the country. In certain cases, this has rendered necessary the substitution of an entirely new essay for the original, as in the case of the articles on Skin Diseases, and on Diseases of the Absorbent System, where the views of the authors have been superseded by the advance of medical science, and new articles have therefore been prepared by Drs. ARTHUR VAN HARLINGEN and S. C. BUSEY, respectively. So also in the case of Anæsthetics, in the use of which American practice differs from that of England, the original has been supplemented with a new essay by J. C. REEVE, M.D., treating not only of the employment of ether and chloroform, but of the other anæsthetic agents of more recent discovery. The same careful and conscientious revision has been pursued throughout, leading to an increase of nearly one-fourth in matter, while the series of illustrations has been more than doubled, and the whole is presented as a complete exponent of British and American Surgery, adapted to the daily needs of the working practitioner.

In order to bring it within the reach of every member of the profession, the five volumes of the original have been compressed into three, by employing a double-columned imperial octavo page, and in this improved form it is offered at less than one-half the price of the original. It is beautifully printed on handsome laid paper and forms a worthy companion to REYNOLDS'S "SYSTEM OF MEDICINE," which has met with so much favor in every section of the country.

The work will be sold by subscription only, and in due time every member of the profession will be called upon and offered an opportunity to subscribe.

The few notices appended will serve to indicate the hearty approval accorded to the unrevised edition on its appearance some years since:—

There is so much that is instructive, even to the experienced practitioner, in their practical and discriminating manner of dealing with mooted questions, none of which seem to be neglected; their abundant illustrations, drawn at once from an unlimited field of hospital experience, and their candid and sensible mode of handling the whole subject, that these particular portions of the work possess a value which places them far above any publication on the same topics yet issued in the language.—*Am. Journ. Med. Sciences.*

The enumeration of the treatises, and the names of the surgical writers from whose pens they proceed, suffice to show that this is no ordinary book, but that in the thousand pages of this goodly volume there is a store of information such as no other surgical work in the language can pretend to offer. Those who are acquainted with the special researches and publications of the respective authors will not fail to notice that by a judicious exercise of editorial discretion, each subject has been entrusted, as far as possible, to a surgeon of the hospitals who is known to have given especial attention to it, and to possess the abilities for summing up with authority the accepted opinions of the day, and adding original matter to the stock.—*London Lancet.*

The work must be considered a very complete account of everything connected with the science and practice of surgery. In conclusion we can cordially recommend this work as a valuable addition to the library of the surgeon.—*Edinburgh Medical Journal.*

It is a cyclopædia of surgery of the most complete and extensive character; and we may justly state that its design and execution do great honor to those concerned, and that the large number and high standing of the authors selected for the various monographs render this "System" what it no doubt was intended to be, representative of the actual state of surgical science and art in the country.—*London Lancet.*

In conclusion, we will add that we can most conscientiously recommend the book to every medical practitioner. In recommending the "*System of Surgery*" to our friends who have to deal in surgical cases, we by no means wish to confine our recommendation to them alone. Every practitioner of medicine may cull something worthy of note from a perusal of this volume.—*The British Med. Journal.*

The four volumes remain a monument to the surgical genius of our day. The great majority of metropolitan surgeons of eminence and proved ability are represented in them; and for many years to come, whoever wishes to know the most authoritative words of English Surgical science on most subjects in the domain of surgery must turn to these pages to read what there is set forth. But taken as a whole it is the most important surgical work which has ever issued from the English press.—*London Lancet.*

BRYANT (*THOMAS*), *F.R.C.S.*,

Surgeon to Guy's Hospital.

THE PRACTICE OF SURGERY. Third American, from the Second and Revised English Edition. Thoroughly revised and much improved, by John B. Roberts, M.D. In one large and very handsome imperial octavo volume of over 1000 pages, with 672 illustrations. Cloth, $6 50; leather, $7 50; very handsome half Russia, raised bands, $8 00. (*Just Ready.*)

Mr. Bryant's work has long been a favorite one with surgeons. As its name indicates, it is of a thoroughly practical character. It is distinctly individual in that it gives the results of the author's large and varied experience as an operator and clinical teacher, and is on that account prized deservedly high as an original work. The style is necessarily condensed, the descriptions of surgical diseases brief and to the point. The illustrations are well chosen, and the typical cases of the author's experience are full of interest, and are of more than ordinary value to the working surgeon.—*N. Y. Medical Record*, March 5, 1881.

It is a work especially adapted to the wants of students and practitioners. While not prolix, it affords instruction in sufficient detail for a full understanding of surgical principles and the treatment of surgical diseases. It embraces in its scope all the diseases that are recognized as belonging to surgery, and all traumatic injuries. In discussing these it has seemed to be the aim of the author rather to present the student with practical information, and that alone, than to burden his memory with the views of different writers, however distinguished they might have been. In this edition the whole work has been carefully revised, much of it has been rewritten, important additions have been made to almost every chapter.—*Cincinnati Med. News*, Jan. 1881.

The English edition, from which this is printed, has been carefully revised and rewritten; almost every chapter has received additions, and nearly one hundred new cuts introduced. The labors of the American editor, Dr. John B Roberts, have very much increased the value of the book. He has introduced many new illustrations and much new material not found in the English edition. He has written too with great conciseness, which is a rare virtue in an American editor of an English work. If one could procure or wished only one surgery, this volume would certainly be selected. If he desired two, Erichsen's Surgery would be added, and if he wished a third, Gross's Surgery would justly be the work selected. As the great work of Gross is amply sufficient for the wants of any surgeon, the priority given to Erichsen, and above all others, to this work of Bryant, is no labored eulogy of the last volume, but a simple and just statement of its demonstrable and pre-eminent merits.—*Am. Med. Bi-Weekly*, Feb. 26, 1881.

ERICHSEN (*JOHN E.*),

Professor of Surgery in University College, London, etc.

THE SCIENCE AND ART OF SURGERY; being a Treatise on Surgical Injuries, Diseases and Operations. Carefully revised by the Author from the Seventh and enlarged English Edition. Illustrated by eight hundred and sixty two engravings on wood. In two large and beautiful octavo volumes of nearly 2000 pages; cloth, $8 50; leather, $10 50; half Russia, $11 50. (*Now Ready.*)

Of the many treatises on Surgery which it has been our task to study, or our pleasure to read, there is none which in all points has satisfied us so well as the classic treatise of Erichsen. His polished, clear style, his freedom from prejudice and hobbies, his unsurpassed grasp of his subject, and vast clinical experience, qualify him admirably to write a model text-book. When we wish, at the least cost of time, to learn the most of a topic in surgery, we turn, by preference, to his work. It is a pleasure, therefore, to see that the appreciation of it is general, and has led to the appearance of another edition.—*Med. and Surg. Reporter*, Feb. 2, 1878.

Notwithstanding the increase in size, we observe that much old matter has been omitted. The entire work has been thoroughly written up, and not merely amended by a few extra chapters A great improvement has been made in the illustrations. One hundred and fifty new ones have been added, and many of the old ones have been redrawn The author highly appreciates the favor with which his work has been received by American surgeons, and has endeavored to render his latest edition more than ever worthy of their approval. That he has succeeded admirably, must, we think, be the general opinion. We heartily recommend the book to both student and practitioner.—*N. Y. Med. Journal*. Feb. 1878.

The seventh edition is before the world as the last word of surgical science. There may be monographs which excel it upon certain points, but as a compendious upon surgical principles and practice it is unrivalled. It will well reward practitioners to read it, for it has been a peculiar province of Mr. Erichsen to demonstrate the absolute interdependence of medical and surgical science We need scarcely add, in conclusion, that we heartily commend the work to students that they may be grounded in a sound faith, and to practitioners as an invaluable guide at the bedside.—*Am. Practitioner*, April, 1878.

For the past twenty years Erichsen's Surgery has maintained its place as the leading text-book, not only in this country, but in Great Britain. That it is able to hold its ground, is abundantly proven by the thoroughness with which the present edition has been revised, and by the large amount of valuable material that has been added. Aside from this, one hundred and fifty new illustrations have been inserted, including quite a number of microscopical appearances of pathological processes. So marked is this change for the better, that the work almost appears as an entirely new one.—*Med. Record*, Feb. 23, 1878.

HOLMES (*TIMOTHY*), *M.D.*,

Surgeon to St. George's Hospital, London.

SURGERY, ITS PRINCIPLES AND PRACTICE. In one handsome octavo volume of nearly 1000 pages, with 411 illustrations. Cloth, $6; leather, $7; half Russia, $7 50.

This is a work which has been looked for on both sides of the Atlantic with much interest. Mr. Holmes is a surgeon of large and varied experience, and one of the best known, and perhaps the most brilliant writer upon surgical subjects in England. It is a book for students—and as admirable one—and for the busy general practitioner. It will give a student all the knowledge needed to pass a rigid examination. The book fairly justifies the high expectations that were formed of it. Its style is clear and forcible, even brilliant at times, and the conciseness needed to bring it within its proper limits has not impaired its force and distinctness.—*N. Y. Med. Record*, April 14, 1876.

It will be found a most excellent epitome of surgery by the general practitioner who has not the time to give attention to more minute and extended works, and to the medical student. In fact, we know of no one we can more cordially recommend. The author has succeeded well in giving a plain and practical account of each surgical injury and disease, and of the treatment which is most commonly advisable. It will no doubt become a popular work in the profession, and especially as a text-book.—*Cincinnati Med. News*, April, 1876.

WELLS (J. SOELBERG),

Professor of Ophthalmology in King's College Hospital, &c.

A TREATISE ON DISEASES OF THE EYE. Third American, from the Third London Edition. Thoroughly revised, with copious additions, by Chas. S. Bull, M.D., Surgeon and Pathologist to the New York Eye and Ear Infirmary. Illustrated with about 250 engravings on wood, and six colored plates Together with selections from the Test-types of Jaeger and Snellen. In one large and very handsome octavo volume of 900 pages. Cloth, $5; leather, $6; half Russia, raised bands, $6 50. (*Just Ready.*)

The long-continued illness of the author, with its fatal termination, has kept this work for some time out of print, and has deprived it of the advantage of the revision which he sought to give it during the last years of his life. This edition has therefore been placed under the editorial supervision of Dr. Bull, who has labored earnestly to introduce in it all the advances which observation and experience have acquired for the theory and practice of ophthalmology since the appearance of the last revision. To accomplish this, considerable additions have been required, and the work is now presented in the confidence that it will fully deserve a continuance of the very marked favor with which it has hitherto been greeted as a complete, but concise, exposition of the principles and facts of its important department of medical science.

The additions made in the previous American editions by Dr. Hays have been retained, including the very full series of illustrations and the test-types of Jaeger and Snellen.

This new edition of Dr. Wells's great work on the eye will be welcomed by the profession at large as well as by the oculist It contains much new matter relating to treatment and pathology, and is brought thoroughly up with the present status of ophthalmology. Its chapter on refraction and accommodation—a subject much discussed of late years, and of great importance—is exceedingly complete.—*Louisville Med. News*, Nov. 13, 1880.

The merits of Wells's treatise on diseases of the eye have been so universally acknowledged, and are so familiar to all who profess to have given any attention to ophthalmic surgery, that any discussion of them at this late day will be a work of supererogation. Very little that is practically useful in recent ophthalmic literature has escaped the editor, and the third American edition is well up to the times. As a text-book on ophthalmic surgery for the English-speaking practitioner, it is without a rival.—*Am. Journ. of Med. Sci.*, Jan. 1881.

The work has justly held a high place in English ophthalmic literature, and at the time of its first appearance was the best treatise of its kind in the language. In the second edition, the author showed industrious research in adding new material from every quarter, and his spirit was eminently candid. A work thus built up by honest effort should not be suffered to die, and we are pleased to receive this third edition from the hands of Dr. Bull. His labor has been arduous, as the very great number of additions bracketed with his initial testify. Under the editorship which the third edition has enjoyed, the work is sure to sustain its good reputation, and to maintain its usefulness.—*N. Y. Med. Journ.*, Jan. 1881.

There is really no work which approaches it in adaptation to the wants of the general practitioner, while the most advanced specialist cannot rise from a perusal of its ample pages without having added to his knowledge. The American editor, Dr. Bull, won his spurs in ophthalmology some time back. His additions to the work of the lamented Wells are many, judicious, and timely, and in just so much have added to its value.—*Am. Practitioner*, Jan. 1881.

NETTLESHIP (EDWARD), F.R.C.S.,

Ophthalmic Surg. and Lect. on Ophth. Surg. at St. Thomas' Hospital, London.

MANUAL OF OPHTHALMIC MEDICINE. In one royal 12mo volume of over 350 pages, with 89 illustrations. Cloth, $2. (*Just Ready.*)

The author is to be congratulated upon the very successful manner in which he has accomplished his task; he has succeeded in being concise without sacrificing clearness, and, including the whole ground covered by more voluminous text-books, has given an excellent *résumé* of all the practical information they contain. We do not hesitate to pronounce Mr Nettleship's book the best manual on ophthalmic surgery for the use of students and "busy practitioners" with which we are acquainted.—*Am. Jour. Med. Sciences*, April, 1880.

CARTER (R. BRUDENELL), F.R.C.S.,

Ophthalmic Surgeon to St. George's Hospital, etc.

A PRACTICAL TREATISE ON DISEASES OF THE EYE. Edited, with test-types and Additions, by JOHN GREEN, M.D. (of St. Louis, Mo.). In one handsome octavo volume of about 500 pages, and 124 illustrations. Cloth, $3 75.

It is with great pleasure that we can endorse the work as a most valuable contribution to practical ophthalmology. Mr. Carter never deviates from the end he has in view, and presents the subject in a clear and concise manner, easy of comprehension, and hence the more valuable. We would especially commend, however, as worthy of high praise, the manner in which the therapeutics of disease of the eye is elaborated, for here the author is particularly clear and practical, where other writers are unfortunately too often deficient. The final chapter is devoted to a discussion of the uses and selection of spectacles, and is admirably compact, plain, and useful, especially the paragraphs on the treatment of presbyopia and myopia. In conclusion, our thanks are due the author for many useful hints in the great subject of ophthalmic surgery and therapeutics, a field where of late years we glean but a few grains of sound wheat from a mass of chaff.—*New York Medical Record*, Oct. 23, 1875.

BROWNE (EDGAR A.),

Surgeon to the Liverpool Eye and Ear Infirmary, and to the Dispensary for Skin Diseases.

HOW TO USE THE OPHTHALMOSCOPE. Being Elementary Instructions in Ophthalmoscopy, arranged for the Use of Students. With thirty-five illustrations. In one small volume royal 12mo. of 120 pages: cloth, $1.

LAURENCE'S HANDY-BOOK OF OPHTHALMIC SURGERY, for the use of Practitioners. Second edition, revised and enlarged With numerous illustrations. In one very handsome octavo volume, cloth, $2 75.

LAWSON'S INJURIES TO THE EYE, ORBIT AND EYELIDS: their Immediate and Remote Effects. With about one hundred illustrations. In one very handsome octavo volume, cloth, $3 50.

BURNETT (CHARLES H.), M.A., M.D.,

Aural Surg. to the Presb. Hosp., Surgeon-in-charge of the Instr. for Dis. of the Ear, Phila.

THE EAR, ITS ANATOMY, PHYSIOLOGY AND DISEASES.

A Practical Treatise for the Use of Medical Students and Practitioners. In one handsome octavo volume of 615 pages, with eighty-seven illustrations: cloth, $4 50; leather, $5 50; half Russia, $6 00. (*Lately Issued.*)

Foremost among the numerous recent contributions to aural literature will be ranked this work of Dr. Burnett. It is impossible to do justice to this volume of over 600 pages in a necessarily brief notice. It must suffice to add that the book is profusely and accurately illustrated, the references are conscientiously acknowledged, while the result has been to produce a treatise which will henceforth rank with the classic writings of Wilde and Von Tröltsch.—*The Lond. Practitioner*, May, 1879.

On account of the great advances which have been made of late years in otology, and of the increased interest manifested in it, the medical profession will welcome this new work, which presents clearly and concisely its present aspect, whilst clearly indicating the direction in which further researches can be most profitably carried on. Dr. Burnett from his own matured experience, and availing himself of the observations and discoveries of others, has produced a work which, as a text-book, stands *facile princeps* in our language. We had marked several passages as well worthy of quotation and the attention of the general practitioner, but their number and the space at our command forbid. Perhaps it is better, as the book ought to be in the hands of every medical student, and its study will well repay the busy practitioner in the pleasure he will derive from the agreeable style in which many otherwise dry and mostly unknown subjects are treated. To the specialist the work is of the highest value, and his sense of gratitude to Dr. Burnett will, we hope, be proportionate to the amount of benefit he can obtain from the careful study of the book, and a constant reference to its trustworthy pages.—*Edinb. Jl Med. Jour.*, Aug. 1878.

TAYLOR (ALFRED S.), M.D.,

Lecturer on Med. Jurisp. and Chemistry in Guy's Hospital.

A MANUAL OF MEDICAL JURISPRUDENCE.

Eighth American edition. Thoroughly revised and rewritten. Edited by JOHN J. REESE, M.D., Prof. of Med. Jurisp. and Toxicology in the Univ. of Penn. In one large octavo volume of 933 pages, with 70 illustrations. Cloth, $5; leather, $6; half Russia, raised bands, $6 50. (*Just Ready.*)

The American editions of this standard manual have for a long time laid claim to the attention of the profession in this country; and that the profession has recognised this claim with favor is proven by the call for frequent new editions of the work. This one, the eighth, comes before us as embodying the latest thoughts and emendations of Dr. Taylor, upon the subject to which he devoted his life, with an assiduity and success which made him *facile princeps* among English writers on medical jurisprudence. Both the author and the book have made a mark too deep to be affected by criticism, whether it be censure or praise. In this case, however, we should only have to seek for laudatory terms.—*Am. Journ. of Med. Sci.*, Jan. 1881.

It is not very often that a medical book reaches its tenth edition, or that the last earthly labor is performed by the author in retouching the work that first came from his hand thirty-five years before. All this, however, has happened in the case of Dr. Taylor and his classical treatise. The pen dropped from the grasp only when the shadows of old age were rapidly deepening into the darkness of death. Under the circumstances, all the journalist has to do is to announce, not criticize, the completed task. The value of the gem is too well known to require more than the telling that the master-hand has relightened its facets and polished its angles before leaving it as his legacy to his brethren in the profession.—*Phila Med. Times*, Dec. 4, 1880.

It will suffice to remark that this new edition shows the signs of judicious revision. A great number of illustrative medico-legal cases which have occurred since the last edition was published are cited in their proper connection, and add much to the interest and value of the work; they comprise the bulk of the additions to the text. As an indication of the freshness of the work, we notice numerous references to medico-legal experience that has transpired during the year just ended; among these is a comment by the American editor upon that midsummer madness, the Tanner fasting exploit of last August. In these features and in others there is ample evidence that this admirable book will maintain its high place as a standard authority concerning the matters of which it treats.—*Boston Med. and Surg. Journal*, Jan. 13, 1881.

BY THE SAME AUTHOR.

THE PRINCIPLES AND PRACTICE OF MEDICAL JURISPRUDENCE.

Second Edition, Revised, with numerous Illustrations. In two large octavo volumes, cloth, $10 00; leather, $12 00

This great work is now recognised in England as the fullest and most authoritative treatise on every department of its important subject. In laying it, in its improved form, before the American profession, the publishers trust that it will assume the same position in this country.

BY THE SAME AUTHOR.

POISONS IN RELATION TO MEDICAL JURISPRUDENCE AND MEDICINE.

Third American, from the Third and Revised English Edition. In one large octavo volume of 850 pages; cloth, $5 50; leather, $6 50.

The present is based upon the two previous editions; "but the complete revision rendered necessary by time has converted it into a new work." This statement from the preface contains all that it is desired to know in reference to the new edition. The works of this author are already in the library of every physician who is liable to be called upon for medico-legal testimony (and what one is not?), so that all that is required to be known about the present book is that the author has kept it abreast with the times. What makes it now, as always, especially valuable to the practitioner is its conciseness and practical character, only those poisonous substances being described which give rise to legal investigations.—*The Climate*, Nov. 6, 1875.

Dr. Taylor has brought to bear on the compilation of this volume, stores of learning, experience, and practical acquaintance with his subject, probably far beyond what any other living authority on toxicology could have amassed or utilized. He has fully sustained his reputation by the consummate skill and legal acumen he has displayed in the arrangement of the subject-matter, and the result is a work on Poisons which will be indispensable to every student or practitioner in law and medicine.—*The Dublin Journ. of Med Sci.*, Oct. 1875.

ROBERTS (*WILLIAM*), *M.D.*,
Lecturer on Medicine in the Manchester School of Medicine, etc.

A PRACTICAL TREATISE ON URINARY AND RENAL DISEASES, including Urinary Deposits. Illustrated by numerous cases and engravings. Third American, from the Third Revised and Enlarged London Edition. In one large and handsome octavo volume of over 600 pages. Cloth, $4. (*Just Ready.*)

THOMPSON (*SIR HENRY*),
Surgeon and Professor of Clinical Surgery to University College Hospital.

LECTURES ON DISEASES OF THE URINARY ORGANS. With illustrations on wood. Second American from the Third English Edition. In one neat octavo volume. Cloth, $2 25.

BY THE SAME AUTHOR.

ON THE PATHOLOGY AND TREATMENT OF STRICTURE OF THE URETHRA AND URINARY FISTULÆ. With plates and wood-cuts. From the third and revised English edition. In one very handsome octavo volume, cloth, $3 50.

TUKE (*DANIEL HACK*), *M.D.*,
Joint author of The Manual of Psychological Medicine, &c.

ILLUSTRATIONS OF THE INFLUENCE OF THE MIND UPON THE BODY IN HEALTH AND DISEASE. Designed to illustrate the Action of the Imagination. In one handsome octavo volume of 416 pages, cloth, $3 25.

BLANDFORD (*G. FIELDING*), *M.D., F.R.C.P.*,
Lecturer on Psychological Medicine at the School of St. George's Hospital, &c.

INSANITY AND ITS TREATMENT: Lectures on the Treatment, Medical and Legal, of Insane Patients. With a Summary of the Laws in force in the United States on the Confinement of the Insane. By ISAAC RAY, M. D. In one very handsome octavo volume of 471 pages; cloth, $3 25.

It satisfies a want which must have been sorely felt by the busy general practitioners of this country. It takes the form of a manual of clinical description of the various forms of insanity, with a description of the mode of examining persons suspected of insanity. We call particular attention to this feature of the book, as giving it a unique value to the general practitioner. If we pass from theoretical considerations to descriptions of the varieties of insanity as actually seen in practice and the appropriate treatment for them, we find in Dr. Blandford's work a considerable advance over previous writings on the subject. His pictures of the various forms of mental disease are so clear and good that no reader can fail to be struck with their superiority to those given in ordinary manuals in the English language or (so far as our own reading extends) in any other.—*London Practitioner*, Feb. 1871.

LEA (*HENRY C.*).

SUPERSTITION AND FORCE: ESSAYS ON THE WAGER OF LAW, THE WAGER OF BATTLE, THE ORDEAL AND TORTURE. Third Revised and Enlarged Edition. In one handsome royal 12mo. volume of 552 pages. Cloth, $2 50. (*Just Ready.*)

This valuable work is in reality a history of civilization as interpreted by the progress of jurisprudence. . . . In "Superstition and Force" we have a philosophic survey of the long period intervening between primitive barbarity and civilized enlightenment. There is not a chapter in the work that should not be most carefully studied, and however well versed the reader may be in the science of jurisprudence, he will find much in Mr. Lea's volume of which he was previously ignorant. The book is a valuable addition to the literature of social science.—*Westminster Review*, Jan. 1880.

The appearance of a new edition of Mr. Henry C. Lea's "Superstition and Force" is a sign that our highest scholarship is not without honor in its native country. Mr. Lea has met every fresh demand for his work with a careful revision of it, and the present edition is not only fuller and, if possible, more accurate than either of the preceding, but, from the thorough elaboration, is more like a harmonious concert and less like a batch of studies.—*The Nation*, Aug. 1, 1878.

Many will be tempted to say that this, like the "Decline and Fall," is one of the uncriticisable books. Its facts are innumerable, its deductions simple and inevitable, and its *chevaux-de-frise* of references bristling and dense enough to make the keenest, stoutest, and best equipped assailant think twice before advancing. Nor is there anything controversial in it to provoke assault. The author is no polemic. Though he obviously feels and thinks strongly, he succeeds in attaining impartiality. Whether looked on as a picture or a mirror, a work such as this has a lasting value.—*Lippincott's Magazine*, Oct. 1878.

BY THE SAME AUTHOR.

STUDIES IN CHURCH HISTORY. THE RISE OF THE TEMPORAL POWER—BENEFIT OF CLERGY—EXCOMMUNICATION. In one large royal 12mo. volume of 516 pp.; cloth, $2 75. (*Lately Published.*)

The story was never told more calmly or with greater learning or wiser thought. We doubt, indeed, if any other study of this field can be compared with this for clearness, accuracy, and power.—*Chicago Examiner*, Dec. 1870.

Mr. Lea's latest work, "Studies in Church History," fully sustains the promise of the first. It deals with three subjects—the Temporal Power, Benefit of Clergy, and Excommunication, the record of which has a peculiar importance for the English student, and is a chapter on Ancient Law likely to be regarded as final. We can hardly pass from our mention of such works as these—with which that on "Sacerdotal Celibacy" should be included—without noting the literary phenomenon that the head of one of the first American houses is also the writer of some of its most original books.—*London Athenæum*, Jan. 7, 1871.

HENRY C. LEA'S SON & CO.—Philadelphia.

STANDARD MEDICAL TEXT-BOOKS.

GYNÆCOLOGY AND OBSTETRICS.

THOMAS ON THE DISEASES OF WOMEN. Fifth edition, thoroughly revised and rewritten. In one handsome 8vo. volume of over 800 pages, with 266 illustrations. Cloth, $5; leather, $6; half Russia, raised bands, $6.50.

EMMET'S PRINCIPLES AND PRACTICE OF GYNÆCOLOGY. Second edition, thoroughly revised. In one handsome 8vo. volume of 875 pages, with 133 illustrations. Cloth, $5; leather, $6; half Russia, raised bands, $6.50.

BARNES ON THE MEDICAL AND SURGICAL DISEASES OF WOMEN. Second American from the Second revised English edition. In one handsome 8vo. volume of 784 pages, with 181 illustrations. Cloth, $4.50; leather, $5.50; half Russia, raised bands, $6.

LEISHMAN'S SYSTEM OF MIDWIFERY. Third American edition, with additions by John S. Parry, M.D. In one handsome 8vo volume of 733 pages, with over 200 illustrations. Cloth, $4.50; leather, $5.50. half Russia, raised bands, $6.

PLAYFAIR'S SCIENCE AND PRACTICE OF MIDWIFERY. Third American edition, with additions by R. P. Harris, M.D. In one handsome 8vo. volume of about 700 pages, with nearly 200 illustrations. Cloth, $4; leather, $5; half Russia, raised bands, $5.50.

RAMSBOTHAM'S PRINCIPLES AND PRACTICE OF OBSTETRIC MEDICINE AND SURGERY. In one imperial 8vo. volume of 650 pages, with 64 plates and numerous engravings. Leather, $7.

SURGERY.

BRYANT'S PRACTICE OF SURGERY. Third American from the Second English edition. Thoroughly revised and enlarged by Jno. B. Roberts, M.D. In one handsome imperial 8vo. volume of over 1000 pages, with 672 illustrations. Cloth, $6.50; leather, $7.50; half Russia, raised bands, $8.

GROSS'S SYSTEM OF SURGERY. Fifth edition, carefully revised and improved. In two imperial 8vo. volumes of about 2300 pages, with about 1400 engravings. Leather, raised bands, $15; half Russia, raised bands, $16.

ERICHSEN'S SCIENCE AND ART OF SURGERY. Carefully revised by the author from the Seventh English edition. In two large 8vo. volumes of nearly 2000 pages, with 862 illustrations. Cloth, $8.50; leather, $10.50; half Russia, raised bands, $11.50.

HOLMES'S SYSTEM OF SURGERY. In treatises by various authors. First American from the Second English edition. Thoroughly revised and with extensive additions by J. H. Packard, M.D, assisted by thirty-two of the most eminent American surgeons. In three imperial 8vo. volumes of about 3000 pages, with about 1000 engravings and 13 colored plates. Per volume, cloth, $6; leather, $7; half Russia, $7.50. Vol. I. (*Just Ready*). (Vols. II. and III. *Shortly*.)

HOLMES'S SURGERY. Its Principles and Practice. In one handsome 8vo. volume of nearly 1000 pages, with 411 illustrations. Cloth, $6; leather, $7; half Russia, raised bands, $7.50.

ASHHURST'S PRINCIPLES AND PRACTICE OF SURGERY. Second edition. In one 8vo. volume of over 1000 pages, with 542 illustrations. Cloth, $6; leather, $7; half Russia, raised bands, $7.50.

BIMSON'S MANUAL OF OPERATIVE SURGERY. In one royal 12mo. volume of about 500 pages, with 332 illustrations. Cloth, $2.50.

DRUITT'S PRINCIPLES AND PRACTICE OF MODERN SURGERY. From the Eighth English edition. In one 8vo. volume of nearly 700 pages, with 432 engravings. Cloth, $4; leather, $5.

MANUALS.

DUNGLISON'S MEDICAL LEXICON. New edition, thoroughly revised and greatly modified and augmented by R. J. Dunglison, M.D. In one large and handsome 8vo. volume of over 1100 pages. Cloth, $6.50; leather, $7.50; half Russia, raised bands, $8.

HOBLYN'S MEDICAL DICTIONARY. Revised, with numerous additions by Isaac Hays, M.D. In one royal 12mo. volume of over 500 double-columned pages. Cloth, $1.50; leather, $2.

HARTSHORNE'S CONSPECTUS OF THE MEDICAL SCIENCES. Second edition, thoroughly revised and much improved. In one royal 12mo. volume of more than 1000 pages, with 477 illustrations. Cloth, $4.25; leather, $5.

NEILL AND SMITH'S ANALYTICAL COMPENDIUM OF THE VARIOUS BRANCHES OF MEDICAL SCIENCE. Second edition. In one royal 12mo. volume of about 1000 pages, with 374 illustrations. Cloth, $4; leather, $4.75.

LUDLOW'S MANUAL OF EXAMINATIONS. Third edition. In one royal 12mo. volume of 816 pages, with 370 illustrations. Cloth, $3.25; leather, $3.75.

PINLAYSON'S CLINICAL DIAGNOSIS. A Handbook for Students and Practitioners of Medicine. In one royal 12mo. volume of 546 pages, with 85 illustrations. Cloth, $2.63.

PENWICK'S STUDENT'S GUIDE TO MEDICAL DIAGNOSIS. From the Third revised English edition. In one royal 12mo. volume of 328 pages, with 84 illustrations. Cloth, $2.25.

FLINT ON PERCUSSION AND AUSCULTATION. Second edition. In one 12mo. volume. Cloth, $1.63.

MEDICAL JURISPRUDENCE.

TAYLOR'S MANUAL OF MEDICAL JURISPRUDENCE. Eighth American edition, thoroughly revised and rewritten, with additions by J. J. Reese, M.D. In one 8vo. volume of 933 pages, with 70 illustrations. Cloth, $5; leather, $6; half Russia, raised bands, $6.50.

TAYLOR ON POISONS IN RELATION TO MEDICAL JURISPRUDENCE AND MEDICINE. Third American from Third revised English edition. In one 8vo. volume of 850 pages. Cloth, $5.50; leather, $6.50.

HENRY C. LEA'S SON & CO.—Philadelphia.

PROSPECTUS FOR 1881.

THE AMERICAN JOURNAL OF THE MEDICAL SCIENCES.

In commencing its sixty-first year, the publishers of the "AMERICAN JOURNAL OF THE MEDICAL SCIENCES" have much pleasure in assuring its wide circle of readers that at no period has it had the prospect of a more extended field of usefulness.

For 1881 the "American Journal" has the promise of its usual variety of important contributions from distinguished members of the profession in all parts of the country. Special attention will be bestowed, as heretofore, on its Bibliographical Department and Quarterly Summaries to keep its subscribers informed as to all subjects of professional interest from every quarter.

With its attendant periodical, "THE MEDICAL NEWS AND ABSTRACT," it combines the advantages of the elaborate preparation which can be given to a quarterly, and the prompt conveyance of intelligence by the monthly, while, the whole being under a single editorial supervision, the subscriber is secured against the duplication of matter inevitable under other circumstances. These efforts the publishers seek to second by offering these periodicals at a price unprecedentedly low—a price which places them within the reach of every practitioner, and gives the equivalent of three large octavo volumes for the comparatively trifling cost of FIVE DOLLARS *per annum*.

The "NEWS AND ABSTRACT" consists of sixty-four pages monthly, in a neat cover. It contains a CLINICAL DEPARTMENT in which will be continued the series of ORIGINAL AMERICAN CLINICAL LECTURES, contributed by gentlemen of the highest reputation throughout the United States, together with a choice selection of Foreign Lectures and Hospital Notes and Gleanings. Then follows the "MONTHLY ABSTRACT," systematically arranged and classified, and presenting five or six hundred articles yearly; each number concluding with an EDITORIAL and a NEWS DEPARTMENT, giving current professional intelligence, domestic and foreign, the whole fully indexed at the close of each volume, rendering it of permanent value for reference.

The subscription price to the "NEWS AND ABSTRACT" will be Two Dollars and a Half per annum, invariably in advance, at which rate it will rank as one of the cheapest medical periodicals in the country. But it will also be furnished, free of all charge, in commutation with the "AMERICAN JOURNAL OF THE MEDICAL SCIENCES," to all who remit FIVE DOLLARS in advance, thus giving to the subscriber, for that very moderate sum, a complete record of medical progress throughout the world, in the compass of about two thousand large octavo pages.

These terms may be recapitulated as follows:—

TERMS FOR 1881.

The AMERICAN JOURNAL OF THE MEDICAL SCIENCES, published quarterly (1150 pages per annum), and The MEDICAL NEWS AND ABSTRACT, published monthly (768 pages per annum),	Five Dollars per annum, in advance.

SEPARATE SUBSCRIPTIONS TO

The AMERICAN JOURNAL OF THE MEDICAL SCIENCES, when not paid for in advance,	Five Dollars.
The MEDICAL NEWS AND ABSTRACT, invariably in advance,	Two Dollars and a Half.

*** Advance-paying subscribers can obtain, at the close of the year, cloth covers, gilt lettered, for binding the volumes of the JOURNAL (two annually) and the NEWS AND ABSTRACT (one annually), free by mail, on remitting ten cents for each cover.

The safest mode of remittance is by bank check or draft, or postal money order drawn to the order of the undersigned. Where these are not accessible, remittances for the "JOURNAL" and "NEWS AND ABSTRACT" may be made at the risk of the publishers by forwarding in REGISTERED letters. Address

THE

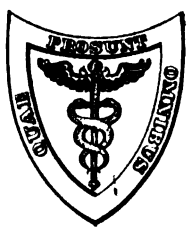
MEDICAL NEWS

AND

ABSTRACT.

EDITED BY

I. MINIS HAYS, A.M., M.D.



PHILADELPHIA:
HENRY C. LEA'S SON & CO.
1881.

PUBLISHED MONTHLY AT $2.50 PER ANNUM IN ADVANCE.
Furnished in conjunction with the Quarterly American Journal of the Medical Sciences (in all nearly 2000 octavo pages) for $5.00 in advance.

Entered according to the Act of Congress, in the year 1881, by HENRY C. LEA'S SON & Co., in the Office of the Librarian of Congress. All rights reserved.

THOMAS (*T. GAILLARD*), *M.D.*,

Professor of Obstetrics, &c., in the College of Physicians and Surgeons, N. Y., &c.

A PRACTICAL TREATISE ON THE DISEASES OF WOMEN. Fifth

Edition, thoroughly revised and rewritten. In one large and handsome octavo volume of over 800 pages, with 266 illustrations. Cloth, $5; leather, $6; very handsome half Russia, raised bands, $6·50. (*Just Ready.*)

The author has taken advantage of the opportunity afforded by the call for a new edition of this work to render it worthy a continuance of the very remarkable favor with which it has been received. Every portion of the work has been carefully revised, very much of it has been rewritten, and additions and alterations introduced wherever the advance of science and the increased experience of the author have shown them desirable. At the same time special care has been exercised to avoid undue increase in the size of the volume. To accommodate the numerous additions a more condensed but very clear letter has been used, notwithstanding which, the number of pages has been increased by more than fifty. The series of illustrations has been extensively changed; many which seemed to be superfluous have been omitted, and a large number of new and superior drawings have been inserted. In its improved form, therefore, it is hoped that the volume will maintain the character it has acquired of a standard authority on every detail of its important subject.

An examination of the work will satisfy that it is one of great merit. It is not a mere compilation from other works, but is the fruit of the ripe thought, sound judgment, and critical observations of a learned, scientific man. It is a treasury of knowledge of the department of medicine to which it is devoted. In its present revised state it certainly holds a foremost position as a gynæcological work, and will continue to be regarded as a standard authority.—*Cincinnati Med. News*, Dec. 1880.

This work needs no introduction to any of the civilized nations of the world. The edition before us adds to the strength of former volumes. With the wisdom of a master teacher he here gives the results that, in his judgment, are most trustworthy at the present time. In its own place it has no rival, because the author is the best teacher on this subject to the masses of the profession. As hitherto this work will be the text-book on diseases of women. We only wish that in other branches of medicine as capable teachers could be found to write our text-books.—*Detroit Lancet*, Jan. 1881.

Since its first appearance, twelve years ago, until the present day, it has held a position of high regard, and is generally conceded to be one of the most practical and trustworthy volumes yet presented to the physician and student in the department of gynæcology. The work embodies not only its author's large experience, but reflects his careful study among other authorities in this branch, both at home and abroad. Dr. Thomas is an able and conscientious teacher. His writings convey his meaning in the same practical and instructive manner. The last edition of this work is fresh from his pen, with decided changes and improvements over former editions. His book presents generally accepted facts, and as a guide to the student is more useful and reliable than any work in the language on diseases of women. This last edition will add new laurels to those already won.—*Md. Med. Journ.*, Nov. 15, 1880.

It has been enlarged and carefully revised. The author has brought it fully abreast with the times, and as the wave of gynæcological progression has been widespread and rapid during the twelve years that have elapsed since the issue of the first edition, one can conceive of the great improvement this edition must be upon the earlier. It is a condensed encyclopædia of gynæcological medicine. The style of arrangement, the masterly manner in which each subject is treated, and the honest convictions derived from probably the largest clinical experience in that specialty of any in this country, all serve to commend it in the highest terms to the practitioner.—*Nashville Journ. of Med. and Surg.*, Jan. 1881.

BARNES (*ROBERT*), *M.D., F.R.C.P.*,

Obstetric Physician to St. Thomas's Hospital, &c.

A CLINICAL EXPOSITION OF THE MEDICAL AND SURGICAL DISEASES OF WOMEN.

Second American, from the Second Enlarged and Revised English Edition. In one handsome octavo volume, of 784 pages, with 181 illustrations. Cloth, $4 50; leather, $5 50; half Russia, $6. (*Lately Issued.*)

Dr Barnes stands at the head of his profession in the old country, and it requires but scant scrutiny of his book to show that it has been sketched by a master. It is plain, practical common sense; shows very deep research without being pedantic; is eminently calculated to inspire enthusiasm without inculcating rashness; points out the dangers to be avoided as well as the success to be achieved in the various operations connected with this branch of medicine; and will do much to smooth the rugged path of the young gynæcologist and relieve the perplexity of the man of mature years.—*Canadian Journ. of Med. Science*, Nov. 1878.

We pity the doctor who, having any considerable practice in diseases of women, has no copy of "Barnes" for daily consultation and instruction. It is at once a book of great learning, research, and individual experience, and at the same time eminently practical. That it has been appreciated by the profession, both in Great Britain and in this country, is shown by the second edition following so soon upon the first.—*Am. Practitioner*, Nov. 1878.

Dr. Barnes's work is one of a practical character, largely illustrated from cases in his own experience, but by no means confined to such, as will be learned from the fact that he quotes from no less than 628 medical authors in numerous countries. Coming from such an author, it is not necessary to say that the work is a valuable one, and should be largely consulted by the profession.—*Am. Supp. Obstetrical Journ. Gt. Britain and Ireland*, Oct. 1878.

No other gynæcological work holds a higher position, having become an authority everywhere in diseases of women. The work has been brought fully abreast of present knowledge. Every practitioner of medicine should have it upon the shelves of his library, and the student will find it a superior text-book.—*Cincinnati Med. News*, Oct. 1878.

HODGE (*HUGH L.*), *M.D.*,

Emeritus Professor of Obstetrics, &c., in the University of Pennsylvania.

ON DISEASES PECULIAR TO WOMEN; including Displacements of the Uterus.

With original illustrations. Second edition, revised and enlarged. In one beautifully printed octavo volume of 531 pages, cloth, $4 50.

EMMET (*THOMAS ADDIS*), *M.D.*,

Surgeon to the Woman's Hospital, New York, etc.

THE PRINCIPLES AND PRACTICE OF GYNÆCOLOGY, for the use of Students and Practitioners of Medicine. Second Edition. Thoroughly Revised. In one large and very handsome octavo volume of 875 pages, with 133 illustrations. Cloth, $5; leather, $6; half Russia, raised bands, $6 50. (*Just Ready.*)

PREFACE TO THE SECOND EDITION.

The unusually rapid exhaustion of a large edition of this work, while flattering to the author as an evidence that his labors have proved acceptable, has in a great measure heightened his sense of responsibility. He has therefore endeavored to take full advantage of the opportunity afforded to him for its revision. Every page has received his earnest scrutiny; the criticisms of his reviewers have been carefully weighed; and while no marked increase has been made in the size of the volume, several portions have been rewritten, and much new matter has been added. In this minute and thorough revision, the labor involved has been much greater than is perhaps apparent in the results, but it has been cheerfully expended in the hope of rendering the work more worthy of the favor which has been accorded to it by the profession.

In no country of the world has gynæcology received more attention than in America. It is, then, with a feeling of pleasure that we welcome a work on diseases of women from so eminent a gynæcologist as Dr. Emmet, and the work is essentially clinical, and leaves a strong impress of the author's individuality. To criticise, with the care it merits, the book throughout, would demand far more space than is at our command. In parting, we can say that the work teems with original ideas, fresh and valuable methods of practice, and is written in a clear and elegant style, worthy of the literary reputation of the country of Longfellow and Oliver Wendell Holmes.—*Brit. Med. Journ.* Feb 21, 1880.

No gynæcological treatise has appeared which contains an equal amount of original and useful matter; nor does the medical and surgical history of America include a book more novel and useful. The tabular and statistical information which it contains is marvellous, both in quantity and accuracy, and cannot be otherwise than invaluable to future investigators. It is a work which demands not careless reading but profound study. Its value as a contribution o gynæcology is, perhaps, greater than that of all previous literature on the subject combined.—*Chicago Med Gaz.*, April 5, 1880

The wide reputation of the author makes its publication an event in the gynæcological world; and a glance through its pages shows that it is a work to be studied with care. . . . It must always be a work to be carefully studied and frequently consulted by those who practise this branch of our profession.—*Lond. Med. Times and Gaz.*, Jan. 10, 1880.

The character of the work is too well known to require extended notice—suffice it to say that no recent work upon any subject has attained such great popularity so rapidly. As a work of general reference upon the subject of Diseases of Women it is invaluable. As a record of the largest clinical experience and observation it has no equal. No physician who pretends to keep up with the advances of this department of medicine can afford to be without it.—*Nashville Journ. of Medicine and Surgery*, May, 1880.

DUNCAN (*J. MATTHEWS*), *M.D., LL.D., F.R.S.E., etc.*

CLINICAL LECTURES ON THE DISEASES OF WOMEN, Delivered in Saint Bartholomew's Hospital. In one very neat octavo volume of 173 pages. Cloth, $1 50. (*Just Ready.*)

They are in every way worthy of their author; indeed, we look upon them as among the most valuable of his contributions. They are all upon matters of great interest to the general practitioner. Some of them deal with subjects that are not, as a rule, adequately handled in the text-books; others of them, while bearing upon topics that are usually treated of at length in such works, yet bear such a stamp of individuality that, if widely read, as they certainly deserve to be, they cannot fail to exert a wholesome restraint upon the undue eagerness with which many young physicians seem bent upon following the wild teachings which so infest the gynæcology of the present day.—*N. Y. Med. Journ.*, March, 1880.

The author is a remarkably clear lecturer, and his discussion of symptoms and treatment is full and suggestive. It will be a work which will not fail to be read with benefit by practitioners as well as by students.—*Phila. Med. and Surg. Reporter*, Feb. 7, 1880.

We have read this book with a great deal of pleasure. It is full of good things. The hints on pathology and treatment scattered through the book are sound, trustworthy, and of great value. A healthy scepticism, a large experience, and a clear judgment are everywhere manifest. Instead of bristling with advice of doubtful value and unsound character, the book is in every respect a safe guide.—*The London Lancet*, Jan. 21, 1880.

RAMSBOTHAM (*FRANCIS H.*), *M.D.*

THE PRINCIPLES AND PRACTICE OF OBSTETRIC MEDICINE AND SURGERY, in reference to the Process of Parturition. A new and enlarged edition, thoroughly revised by the author. With additions by W. V. KEATING, M. D., Professor of Obstetrics, &c., in the Jefferson Medical College, Philadelphia. In one large and handsome imperial octavo volume of 650 pages, strongly bound in leather, with raised bands; with sixty-four beautiful plates, and numerous wood-cuts in the text, containing in all nearly 200 large and beautiful figures. $7 00

PARRY (*JOHN S.*), *M.D.*,

Obstetrician to the Philadelphia Hospital, Vice-Pres't of the Obstet Society of Philadelphia.

EXTRA-UTERINE PREGNANCY: ITS CLINICAL HISTORY, DIAGNOSIS, PROGNOSIS AND TREATMENT. In one handsome octavo volume. Cloth, $2 50.

TANNER (*THOMAS H.*), *M.D.*

ON THE SIGNS AND DISEASES OF PREGNANCY. First American from the Second and Enlarged English Edition. With four colored plates and illustrations on wood. In one handsome octavo volume of about 500 pages, cloth, $4 25.

LEISHMAN (*WILLIAM*), *M.D.*,

Regius Professor of Midwifery in the University of Glasgow, &c.

A SYSTEM OF MIDWIFERY, INCLUDING THE DISEASES OF PREGNANCY AND THE PUERPERAL STATE.

Third American edition, revised by the Author, with additions by JOHN S. PARRY, M.D., Obstetrician to the Philadelphia Hospital, &c. In one large and very handsome octavo volume, of 738 pages, with over two hundred illustrations. Cloth, $4 50; leather, $5 50; half Russia, $6. (*Just Ready.*)

Few works on this subject have met with as great a demand as this one appears to have. To judge by the frequency with which its author's views are quoted, and its statements referred to in obstetrical literature, one would judge that there are few physicians devoting much attention to obstetrics who are without it. The author is evidently a man of ripe experience and conservative views, and in no branch of medicine are these more valuable than in this.—*New Remedies*, Jan. 1880.

We gladly welcome the new edition of this excellent text-book of midwifery. The former editions have been most favorably received by the profession on both sides of the Atlantic In the preparation of the present edition the author has made such alterations as the progress of obstetrical science seems to require, and we cannot but admire the ability with which the task has been performed. We consider it an admirable text-book for students during their attendance upon lectures, and have great pleasure in recommending it. As an exponent of the midwifery of the present day it has no superior in the English language.—*Canada Lancet*, Jan. 1880.

To the American student the work before us must prove admirably adapted, complete in all its parts, essentially modern in its teachings and with demonstrations noted for clearness and precision, it will gain in favor and be recognized as a work of standard merit. The work cannot fail to be popular, and is cordially recommended.—*N. O. Med. and Surg. Journ.*, March, 1880.

PLAYFAIR (*W. S.*), *M.D.*, *F.R.C.P.*,

Professor of Obstetric Medicine in King's College, etc. etc.

A TREATISE ON THE SCIENCE AND PRACTICE OF MIDWIFERY.

Third American edition, revised by the author. Edited, with additions, by ROBERT P. HARRIS, M.D. In one handsome octavo volume of about 700 pages, with nearly 200 illustrations. Cloth, $4; leather, $5; half Russia, $5 50. (*Just Ready.*)

The medical profession has now the opportunity of adding to their stock of standard medical works one of the best volumes on midwifery ever published. The subject is taken up with a master hand. The part devoted to labor in all its various presentations, the management and results, is admirably arranged, and the views entertained will be found essentially modern, and the opinions expressed trustworthy The work abounds with plates, illustrating various obstetrical positions; they are admirably wrought, and afford great assistance to the student.—*N. O. Med. and Surg. Journ.*, March, 1880.

If inquired of by a medical student what work on obstetrics we should recommend for him, as *par excellence*, we would undoubtedly advise him to choose Playfair's. It is of convenient size, but what is of chief importance, its treatment of the various subjects is concise and plain. While the discussions and descriptions are sufficiently elaborate to render a very intelligent idea of them, yet all details not necessary for a full understanding of the subject are omitted.—*Cincinnati Med. News*, Jan. 1880.

The rapidity with which one edition of this work follows another is proof alike of its excellence and of the estimate that the profession has formed of it. It is indeed so well known and so highly valued that nothing need be said of it as a whole. All things considered, we regard this treatise as the very best on Midwifery in the English language.—*N. Y. Medical Journal*, May, 1880

It certainly is an admirable exposition of the Science and Practice of Midwifery. Of course the additions made by the American editor, Dr. R. P. Harris, who never utters an idle word, and whose studious researches in some special departments of obstetrics are so well known to the profession, are of great value.—*The American Practitioner*, April, 1880.

BARNES (*FANCOURT*), *M.D.*,

Physician to the General Lying-in Hospital, London.

A MANUAL OF MIDWIFERY FOR MIDWIVES AND MEDICAL STUDENTS.

With 50 illustrations. In one neat royal 12mo. volume of 200 pages; cloth, $1 25. (*Now Ready.*)

PARVIN (*THEOPHILUS*), *M.D.*,

Prof. of Obstetrics and of the Med. and Surg. Diseases of Women in the Med. Coll. of Indiana.

A TREATISE ON MIDWIFERY.

In one very handsome octavo volume of about 550 pages, with numerous illustrations. (*Preparing.*)

HODGE (*HUGH L.*), *M.D.*,

Emeritus Professor of Midwifery, &c., in the University of Pennsylvania, &c.

THE PRINCIPLES AND PRACTICE OF OBSTETRICS.

Illustrated with large lithographic plates containing one hundred and fifty-nine figures from original photographs, and with numerous wood-cuts. In one large and beautifully printed quarto volume of 550 double-columned pages, strongly bound in cloth. $14.

The work of Dr. Hodge is something more than a simple presentation of his particular views in the department of Obstetrics; it is something more than an ordinary treatise on midwifery; it is, in fact, a cyclopædia of midwifery. He has aimed to embody in a single volume the whole science and art of Obstetrics. An elaborate text is combined with accurate and varied pictorial illustrations, so that no fact or principle is left unstated or unexplained. —*Am. Med. Times*, Sept 3, 1864.

*** Specimens of the plates and letter-press will be forwarded to any address, free by mail, on receipt of six cents in postage stamps.

CHADWICK (*JAMES R.*), *A.M.*, *M.D.*

A MANUAL OF THE DISEASES PECULIAR TO WOMEN.

In one neat volume, royal 12mo., with illustrations. (*Preparing.*)

HAMILTON (FRANK H.) M.D., LL.D.,

Surgeon to the Bellevue Hospital, New York.

A PRACTICAL TREATISE ON FRACTURES AND DISLOCATIONS

Sixth Edition, thoroughly revised, and much improved. In one very handsome octavo volume of over 900 pages, with 352 illustrations. Cloth, $5 50; leather, $6 50; half Russia, raised bands, $7 00. (*Just Ready.*)

So many kind expressions of welcome have been showered upon each successive edition of this valuable treatise, that scarcely anything remains for us to do but to extend the customary cordial greeting. It is the only complete work on the subject of Fractures in the English language We congratulate the accomplished author on the deserved success of his work, and hope that he may live to have many succeeding editions pass under his skilled supervision.—*Phila. Coll. and Clin. Record*, Nov 15. 1880.

Universal verdict has pronounced it, humanly speaking, a perfect treat se upon this subject. As it is the only complet and illustrated work in any language treating of fractures and dislocations, it is safe to affirm that every wide-awake surgeon and general practitioner will regard it as indispensable to the safe and pleasant conduct of their professional work.—*Detroit Lancet*, Nov. 18, 1880.

Dr Hamilton has devoted great labor to the study of these subjects. His large experience, extended research, and patient investigation have made him one of the highest authorities among living writers in this branch of surgery This work is systematic and practical in its arrangement. and presents its subject matter clearly and forcibly to the reader or student.—*Maryland Medical Journal*, Nov. 15, 1880.

The only complete work on its subject in the English tongne, and, indeed, may now be said to be the only work of its kind in any tongue. It would require an exceedingly critical examination to detect in it any particulars in which t might be improved. The work is a monument to American surgery, and will long serve to keep green the memory of its venerable author.—*Michigan Med. News*, Nov. 10, 1851.

ASHHURST (JOHN, Jr.), M.D.,

Prof. of Clinical Surgery, Univ. of Pa., Surgeon to the Episcopal Hospital, Philadelphia.

THE PRINCIPLES AND PRACTICE OF SURGERY.

Second Edition, enlarged and revised. In one very large and handsome octavo volume of over 1000 pages, with 542 illustrations. Cloth, $6; leather, $7; half Russia, $7 50. (*Just Issued.*)

Conscientiousness and thoroughness are two very marked traits of character in the author of this book. Out of these traits largely has grown the success of his mental fruit in the past, and the present offer seems in no wise an exception to what has gone before. The general arrangement of the volume is the same as in the first edition, but every part has been carefully revised, and much new matter added.—*Phila. Med. Times*, Feb. 1, 1879.

The favorable reception of the first edition is a guarantee of the popularity of this edition, which is fresh from the editor's hands with many enlargements and improvements. The author of this work is deservedly popular as an editor and writer, and his contributions to the literature of surgery have gained for him wide reputation. The volume now offered the profession will add new laurels to those already won by previous contributions. We can only add that the work is well arranged, filled with practical matter, and contains in brief and clear language all that is necessary to be learned by the student of surgery whilst in attendance upon lectures, or the general practitioner in his daily routine practice.—*Md. Med. Journal*, Jan. 1879.

The fact that this work has reached a second edition so very soon after the publication of the first one, speaks more highly of its merits than anything we might say in the way of commendation. It seems to have immediately gained the favor of students and physicians.—*Cincin. Med. News*, Jan. '79.

We have previously spoken of Dr. Ashhurst's work in terms of praise. We wish to reiterate those terms here, and to add that no more satisfactory representation of modern surgery has yet fallen from the press. In point of judicial fairness, of power of condensation, of accuracy and conciseness of expression and thoroughly good English, Prof. Ashhurst has no superior among the surgical writers in America.—*Am. Practitioner*, Jan. 1879.

STIMSON (LEWIS A.), A.M., M.D.,

Surgeon to the Presbyterian Hospital.

A MANUAL OF OPERATIVE SURGERY.

In one very handsome royal 12mo. volume of about 500 pages, with 332 illustrations; cloth, $2 50.

The work before us is a well printed, profusely illustrated manual of over four hundred and seventy pages. The novice, by a perusal of the work, will gain a good idea of the general domain of operative surgery, while the practical surgeon has presented to him within a very concise and intelligible form the latest and most approved selections of operative procedure. The precision and conciseness with which the different operations are described enable the author to compress an immense amount of practical information in a very small compass.—*N. Y. Medical Record*, Aug. 3, 1878.

This volume is devoted entirely to operative surgery, and is intended to familiarize the student with the details of operations and the different modes of performing them. The work is handsomely illustrated, and the descriptions are clear and well drawn. It is a clever and useful volume; every student should possess one. The preparation of this work does away with the necessity of pondering over larger works on surgery for descriptions of operations, as it presents in a nut-shell just what is wanted by the surgeon without an elaborate search to find it.—*Md. Med Journal*, Aug. 1878.

The author's conciseness and the repleteness of the work with valuable illustrations entitle it to be classed with the text-books for students of operative surgery, and as one of reference to the practitioner. —*Cincinnati Lancet and Clinic*, July 27, 1878.

KEY'S OPERATIVE SURGERY. In 1 vol. 8vo. cl., of 650 pages; with about 100 wood-cuts. $3 25

COOPER'S LECTURES ON THE PRINCIPLES AND PRACTICE OF SURGERY. In 1 vol. 8vo. cl'h, 750 p. $2.

DIBSON'S INSTITUTES AND PRACTICE OF SURGERY. Eighth edit'n, improved and altered. With thirty-four plates. In two handsome octavo volumes, about 1000 pp. leather. raised bands. $6 50.

THE PRINCIPLES AND PRACTICE OF SURGERY. By WILLIAM PIRRIE, F.R S.E., Professor of Surgery in the University of Aberdeen. Edited by JOHN NEILL, M.D., Professor of Surgery in the Penna. Medical College, Surg'n to the Pennsylvania Hospital, &c. In one very handsome octavo vol. of 780 pages, with 316 illustrations, cloth, $3 75.

MILLER'S PRINCIPLES OF SURGERY. Fourth American, from the Third Edinburgh Edition. In one large 8vo. vol. of 700 pages, with 340 illustrations, cloth, $3 75.

MILLER'S PRACTICE OF SURGERY. Fourth American, from the last Edinburgh Edition Revised by the American editor. In one large 8vo. vol. of nearly 700 pages, with 364 illustrations: cloth, $3 75.

GROSS (SAMUEL D.), M.D.,

Professor of Surgery in the Jefferson Medical College of Philadelphia.

A SYSTEM OF SURGERY: Pathological, Diagnostic, Therapeutic and Operative. Illustrated by upwards of Fourteen Hundred Engravings. Fifth edition, carefully revised and improved. In two large and beautifully printed imperial octavo volumes of about 2300 pp., strongly bound in leather, with raised bands, $15; half Russia, raised bands, $16.

We have seldom read a work with the practical value of which we have been more impressed. Every chapter is so concisely put together, that the busy practitioner, when in difficulty, can at once find the information he requires. His work is cosmopolitan, the surgery of the world being fully represented in it. The work, in fact, is so historically unprejudiced, and so eminently practical, that it is almost a false compliment to say that we believe it to be destined to occupy a foremost place as a work of reference, while a system of surgery like the present system of surgery is the practice of surgeons. The printing and binding of the work is unexceptionable; indeed, it contrasts, in the latter respect, remarkably with English medical and surgical cloth-bound publications, which are generally so wretchedly stitched as to require re-binding before they are any time in use.—*Dub. Journ. of Med. Sci.*, March, 1874.

Dr. Gross's Surgery, a great work, has become still greater, both in size and merit, in its most recent form. The difference in actual number of pages is not more than 130, but the size of the page having been increased to what we believe is technically termed "elephant," there has been room for considerable additions, which, together with the alterations, are improvements.—*Lond. Lancet*, Nov. 16, 1872.

It combines, as perfectly as possible, the qualities of a text-book and work of reference. We think this last edition of Gross's "Surgery," will confirm his title of "*Primus inter Pares*." It is learned, scholar-like, methodical, precise, and exhaustive. We scarcely think any living man could write so complete and faultless a treatise, or comprehend more solid, instructive matter in the given number of pages. The labor must have been immense, and the work gives evidence of great powers of mind, and the highest order of intellectual discipline and methodical disposition and arrangement of acquired knowledge and personal experience.—*N.Y. Med. Journ.*, Feb 1873.

As a whole, we regard the work as the representative "System of Surgery" in the English language.—*St. Louis Medical and Surg. Journ.*, Oct. 1872.

The two magnificent volumes before us afford a very complete view of the surgical knowledge of the day. Some years ago we had the pleasure of presenting the first edition of Gross's Surgery to the profession as a work of unrivalled excellence; and now we have the result of years of experience, labor, and study, all condensed upon the great work before us. And to students or practitioners desirous of enriching their library with a treasure of reference, we can simply commend the purchase of these two volumes of immense research.—*Cincinnati Lancet and Observer*, Sept. 1872.

A complete system of surgery—not a mere text-book of operations, but a scientific account of surgical theory and practice in all its departments.—*Brit. and For. Med. Chir. Rev.*, Jan. 1873.

BY THE SAME AUTHOR.

A PRACTICAL TREATISE ON THE DISEASES, INJURIES and Malformations of the Urinary Bladder, the Prostate Gland and the Urethra. Third Edition, thoroughly Revised and Condensed, by SAMUEL W. GROSS, M.D., Surgeon to the Philadelphia Hospital. In one handsome octavo volume of 574 pages, with 170 illustrations: cloth, $4 50.

For reference and general information, the physician or surgeon can find no work that meets their necessities more thoroughly than this, a revised edition of an excellent treatise, and no medical library should be without it. Replete with handsome illustrations and good ideas, it has the unusual advantage of being easily comprehended, by the reasonable and practical manner in which the various subjects are systematized and arranged. We heartily recommend it to the profession as a valuable addition to the important literature of diseases of the urinary organs.—*Atlanta Med. Journ.*, Oct. 1876.

It is with pleasure we now again take up this old work in a decidedly new dress. Indeed, it must be regarded as a new book in very many of its parts. The chapters on "Diseases of the Bladder," "Prostate Body," and "Lithotomy," are splendid specimens of descriptive writing; while the chapter on "Stricture" is one of the most concise and clear that we have ever read.—*New York Med. Journ.*, Nov. 1876.

BY THE SAME AUTHOR.

A PRACTICAL TREATISE ON FOREIGN BODIES IN THE AIR-PASSAGES. In 1 vol. 8vo., with illustrations, pp. 468, cloth, $2 75.

DRUITT (ROBERT), M.R.C.S., &c.

THE PRINCIPLES AND PRACTICE OF MODERN SURGERY.

A new and revised American, from the Eighth enlarged and improved London edition. Illustrated with four hundred and thirty-two wood engravings. In one very handsome octavo volume, of nearly 700 large and closely printed pages, cloth, $4 00; leather, $5 00.

All that the surgical student or practitioner could desire.—*Dublin Quarterly Journal.*

It is a most admirable book. We do not know when we have examined one with more pleasure.—*Boston Med. and Surg. Journal.*

In Mr. Druitt's book, though containing only some seven hundred pages, both the principles and the practice of surgery are treated, and so clearly and perspicuously, as to elucidate every important topic. We have examined the book most thoroughly, and can say that this success is well merited. His book, moreover, possesses the inestimable advantages of having the subjects perfectly well arranged and classified and of being written in a style at once clear and succinct.—*Am. Journal of Med. Sciences.*

ASHTON ON THE DISEASES, INJURIES, AND MALFORMATIONS OF THE RECTUM AND ANUS: with remarks on Habitual Constipation. Second American, from the Fourth and enlarged London Edition. With illustrations. In one 8vo. vol. of 287 pages, cloth, $3 25.

SARGENT ON BANDAGING AND OTHER OPERATIONS OF MINOR SURGERY. New edition, with an additional chapter on Military Surgery. One 12mo. vol. of 383 pages with 184 wood-cuts. Cloth, $1 75.

HOLMES (*TIMOTHY*), *M. A.*,

Surgeon and Lecturer on Surgery at St. George's Hospital, London.

A SYSTEM OF SURGERY; THEORETICAL AND PRACTICAL.

IN TREATISES BY VARIOUS AUTHORS. AMERICAN EDITION, THOROUGHLY REVISED AND REWRITTEN by JOHN H. PACKARD, M.D., Surgeon to the Episcopal and St. Joseph's Hospitals, Philadelphia, assisted by a large corps of the most eminent American surgeons. In three large and very handsome imperial octavo volumes of about 1000 pages each, with over 1000 illustrations on wood and thirteen lithographic plates, beautifully colored. (*Sold only by subscription.*) Price per volume, in cloth, $6 00; in leather, $7 00; in half Russia, $7 50. Per set, in cloth, $18 00; in leather, $21 00; in half Russia, $22 50.

VOLUME I. (*now ready*) contains GENERAL PATHOLOGY, MORBID PROCESSES, INJURIES IN GENERAL, COMPLICATIONS OF INJURIES AND INJURIES OF REGIONS.

VOLUME II. (*shortly*) contains DISEASES OF ORGANS OF SPECIAL SENSE, CIRCULATORY SYSTEM, DIGESTIVE TRACT AND GENITO-URINARY ORGANS.

VOLUME III. (*shortly*) contains DISEASES OF THE RESPIRATORY ORGANS, JOINTS, BONES, AND MUSCLES, OPERATIVE AND MINOR SURGERY, GUNSHOT WOUNDS, HOSPITALS AND MISCELLANEOUS SUBJECTS.

This great work, issued some years since in England, has won such universal confidence wherever the language is spoken, that its republication here, in a form more thoroughly adapted to the wants of the American practitioner, has seemed to be a duty owing to the profession.

To accomplish this, the aid has been invited of thirty-three of the most distinguished gentlemen, in every part of the country, and for more than a year they have been assiduously engaged upon the task. Though the original work presents the combined labor of the most eminent members of all the most prominent schools of England, yet the lapse of time since the appearance of the last edition, the progress of science, and the peculiarities of American practice, have rendered necessary a most careful, thorough, and searching revision. Each article has been placed in the hands of a gentleman specially competent to treat its subject, and no labor has been spared to bring each one up to the foremost level of the times, and to adapt it thoroughly to the practice of the country. In certain cases, this has rendered necessary the substitution of an entirely new essay for the original, as in the case of the articles on Skin Diseases, and on Diseases of the Absorbent System, where the views of the authors have been superseded by the advance of medical science, and new articles have therefore been prepared by Drs. ARTHUR VAN HARLINGEN and S. C. BUSEY, respectively. So also in the case of Anæsthetics, in the use of which American practice differs from that of England, the original has been supplemented with a new essay by J. C. REEVE, M.D., treating not only of the employment of ether and chloroform, but of the other anæsthetic agents of more recent discovery. The same careful and conscientious revision has been pursued throughout, leading to an increase of nearly one-fourth in matter, while the series of illustrations has been more than doubled, and the whole is presented as a complete exponent of British and American Surgery, adapted to the daily needs of the working practitioner.

In order to bring it within the reach of every member of the profession, the five volumes of the original have been compressed into three, by employing a double-columned imperial octavo page, and in this improved form it is offered at less than one-half the price of the original. It is beautifully printed on handsome laid paper and forms a worthy companion to REYNOLDS'S "SYSTEM OF MEDICINE," which has met with so much favor in every section of the country.

The work will be sold by subscription only, and in due time every member of the profession will be called upon and offered an opportunity to subscribe.

The few notices appended will serve to indicate the hearty approval accorded to the unrevised edition on its appearance some years since:—

There is so much that is instructive, even to the experienced practitioner, in their practical and discriminating manner of dealing with mooted questions, none of which seem to be neglected; their abundant illustrations, drawn at once from an unlimited field of hospital experience, and their candid and sensible mode of handling the whole subject, that these particular portions of the work possess a value which places them far above any publication on the same topics yet issued in the language.—*Am. Journ. Med. Sciences.*

The enumeration of the treatises, and the names of the surgical writers from whose pens they proceed, suffice to show that this is no ordinary book, but that in the thousand pages of this goodly volume we see a store of information such as no other surgical work in the language can pretend to offer. Those who are acquainted with the special researches and publications of the respective authors will not fail to notice that by a judicious exercise of editorial discretion, each subject has been entrusted, as far as possible, to a surgeon of the hospitals who is known to have given especial attention to it, and to possess facilities for summing up with authority the accepted opinions of the day, and adding original matter to the stock.—*London Lancet.*

The work must be considered a very complete account of everything connected with the science and practice of surgery. In conclusion we can cordially recommend this work as a valuable addition to the library of the surgeon.—*Edinburgh Medical Journal.*

It is a cyclopædia of surgery of the most complete and extensive character; and we may justly state that its design and execution do great honor to those concerned, and that the large number and high standing of the authors selected for the various monographs render this "System" what it no doubt was intended to be, representative of the actual state of surgical science and art in the country.—*London Lancet.*

In conclusion, we will add that we can most conscientiously recommend the book to every medical practitioner. In recommending the "*System of Surgery*" to our friends who have to deal in surgical cases, we by no means wish to confine our recommendation to them alone. Every practitioner of medicine may cull something worthy of note from a perusal of this volume.—*The British Med. Journal.*

The four volumes remain a monument to the surgical genius of our day. The great majority of metropolitan surgeons of eminence and proved ability are represented in them; and for many years to come, whoever wishes to know the most authoritative words of English Surgical science on most subjects in the domain of surgery must turn to these pages to read what there is set forth. But taken as a whole it is the most important surgical work which has ever issued from the English press.—*London Lancet.*

BRYANT (*THOMAS*), *F.R.C.S.*,
Surgeon to Guy's Hospital.

THE PRACTICE OF SURGERY. Third American, from the Second and Revised English Edition. Thoroughly revised and much improved, by John B. Roberts, M.D. In one large and very handsome imperial octavo volume of over 1000 pages, with 672 illustrations. Cloth, $6 50; leather, $7 50; very handsome half Russia, raised bands, $8 00. (*Just Ready.*)

Mr. Bryant's work has long been a favorite one with surgeons. As its name indicates, it is of a thoroughly practical character. It is distinctly individual in that it gives the results of the author's large and varied experience as an operator and clinical teacher, and is on that account prized deservedly high as an original work. The style is necessarily condensed, the descriptions of surgical diseases brief and to the point. The illustrations are well chosen, and the typical cases of the author's experience are full of interest, and are of more than ordinary value to the working surgeon.—*N. Y. Medical Record*, March 5, 1881.

It is a work especially adapted to the wants of students and practitioners. While not prolix, it affords instruction in sufficient detail for a full understanding of surgical principles and the treatment of surgical diseases. It embraces in its scope all the diseases that are recognized as belonging to surgery, and all traumatic injuries. In discussing these it has seemed to be the aim of the author rather to present the student with practical information, and that alone, than to burden his memory with the views of different writers, however distinguished they might have been. In this edition the whole work has been carefully revised, much of it has been rewritten, important additions have been made to almost every chapter.—*Cincinnati Med. News*, Jan. 1881.

The English edition, from which this is printed, has been carefully revised and rewritten; almost every chapter has received additions, and nearly one hundred new cuts introduced. The labors of the American editor, Dr. John B Roberts, have very much increased the value of the book. He has introduced many new illustrations and much new material not found in the English edition. He has written too with great conciseness, which is a rare virtue in an American editor of an English work. If one could procure or wished only one surgery, this volume would certainly be selected. If he desired two, Erichsen's Surgery would be added, and if he wished a third, Gross's Surgery would justly be the work selected. As the great work of Gross is amply sufficient for the wants of any surgeon, the priority given to Erichsen, and above all others, to this work of Bryant, is no labored eulogy of the last volume, but a simple and just statement of its demonstrable and pre-eminent merits.—*Am. Med. Bi-Weekly*, Feb. 26, 1881.

ERICHSEN (*JOHN E.*),
Professor of Surgery in University College, London, etc.

THE SCIENCE AND ART OF SURGERY; being a Treatise on Surgical Injuries, Diseases and Operations. Carefully revised by the Author from the Seventh and enlarged English Edition. Illustrated by eight hundred and sixty two engravings on wood. In two large and beautiful octavo volumes of nearly 2000 pages: cloth, $8 50; leather, $10 50; half Russia, $11 50. (*Now Ready.*)

Of the many treatises on Surgery which it has been our task to study, or our pleasure to read, there is none which in all points has satisfied us so well as the classic treatise of Erichsen. His polished, clear style, his freedom from prejudice and hobbies, his unsurpassed grasp of his subject, and vast clinical experience, qualify him admirably to write a model text-book. When we wish, at the least cost of time, to learn the most of a topic in surgery, we turn, by preference, to his work. It is a pleasure, therefore, to see that the appreciation of it is general, and has led to the appearance of another edition.—*Med. and Surg. Reporter*, Feb. 2, 1878.

Notwithstanding the increase in size, we observe that much old matter has been omitted. The entire work has been thoroughly written up, and not merely amended by a few extra chapters A great improvement has been made in the illustrations. One hundred and fifty new ones have been added, and many of the old ones have been redrawn. The author highly appreciates the favor with which his work has been received by American surgeons, and has endeavored to render his latest edition more than ever worthy of their approval. That he has succeeded admirably, must, we think, be the general opinion. We heartily recommend the book to both student and practitioner.—*N. Y. Med. Journal*, Feb. 1878.

The seventh edition is before the world as the last word of surgical science. There may be monographs which excel it upon certain points, but as a conspectus upon surgical principles and practice it is unrivalled. It will well reward practitioners to read it, for it has been a peculiar province of Mr. Erichsen to demonstrate the absolute interdependence of medical and surgical science We need scarcely add, in conclusion, that we heartily commend the work to students that they may be grounded in a sound faith, and to practitioners as an invaluable guide at the bedside.—*Am Practitioner*, April, 1878.

For the past twenty years Erichsen's Surgery has maintained its place as the leading text-book, not only in this country, but in Great Britain. That it is able to hold its ground, is abundantly proven by the thoroughness with which the present edition has been revised, and by the large amount of valuable material that has been added. Aside from this, one hundred and fifty new illustrations have been inserted, including quite a number of microscopical appearances of pathological processes. So marked is this change for the better, that the work almost appears as an entirely new one.—*Med. Record*, Feb. 23, 1878.

HOLMES (*TIMOTHY*), *M.D.*,
Surgeon to St. George's Hospital, London.

SURGERY, ITS PRINCIPLES AND PRACTICE. In one handsome octavo volume of nearly 1000 pages, with 411 illustrations. Cloth, $6; leather, $7; half Russia, $7 50.

This is a work which has been looked for on both sides of the Atlantic with much interest. Mr. Holmes is a surgeon of large and varied experience, and one of the best known, and perhaps the most brilliant writer upon surgical subjects in England. It is a book for students—and an admirable one—and for the busy general practitioner. It will give a student all the knowledge needed to pass a rigid examination. The book fairly justifies the high expectations that were formed of it. Its style is clear and forcible, even brilliant at times, and the conciseness needed to bring it within its proper limits has not impaired its force and distinctness.—*N. Y. Med. Record*, April 14, 1876.

It will be found a most excellent epitome of surgery by the general practitioner who has not the time to give attention to more minute and extended works, and to the medical student. In fact, we know of no one we can more cordially recommend. The author has succeeded well in giving a plain and practical account of each surgical injury and disease, and of the treatment which is most commonly advisable. It will no doubt become a popular work in the profession, and especially as a text-book.—*Cincinnati Med. News*, April, 1876.

WELLS (*J. SOELBERG*),
Professor of Ophthalmology in King's College Hospital, &c.

A TREATISE ON DISEASES OF THE EYE. Third American,

from the Third London Edition. Thoroughly revised, with copious additions, by Chas. S. Bull, M D., Surgeon and Pathologist to the New York Eye and Ear Infirmary. Illustrated with about 250 engravings on wood, and six colored plates Together with selections from the Test-types of Jaeger and Snellen. In one large and very handsome octavo volume of 900 pages. Cloth, $5; leather, $6; half Russia, raised bands, $6 50. (*Just Ready.*)

The long-continued illness of the author, with its fatal termination, has kept this work for some time out of print, and has deprived it of the advantage of the revision which he sought to give it during the last years of his life. This edition has therefore been placed under the editorial supervision of Dr. Bull, who has labored earnestly to introduce in it all the advances which observation and experience have acquired for the theory and practice of ophthalmology since the appearance of the last revision. To accomplish this, considerable additions have been required, and the work is now presented in the confidence that it will fully deserve a continuance of the very marked favor with which it has hitherto been greeted as a complete, but concise, exposition of the principles and facts of its important department of medical science.

The additions made in the previous American editions by Dr. Hays have been retained, including the very full series of illustrations and the test-types of Jaeger and Snellen.

This new edition of Dr. Wells's great work on the eye will be welcomed by the profession at large as well as by the oculist It contains much new matter relating to treatment and pathology, and is brought thoroughly up with the present status of ophthalmology. Its chapter on refraction and accommodation—a subject much discussed of late years, and of great importance—is exceedingly complete.—*Louisville Med. News*, Nov. 13, 1880.

The merits of Wells's treatise on diseases of the eye have been so universally acknowledged, and are so familiar to all who profess to have given any attention to ophthalmic surgery, that any discussion of them at this late day will be a work of supererogation. Very little that is practically useful in recent ophthalmic literature has escaped the editor, and the third American edition is well up to the times. As a text-book on ophthalmic surgery for the English-speaking practitioner, it is without a rival.—*Am. Journ. of Med. Sci.*, Jan. 1881.

The work has justly held a high place in English ophthalmic literature, and at the time of its first appearance was the best treatise of its kind in the language. In the second edition, the author showed industrious research in adding new material from every quarter, and his spirit was eminently candid. A work thus built up by honest effort should not be suffered to die, and we are pleased to receive this third edition from the hands of Dr. Bull. His labor has been arduous, as the very great number of additions bracketed with his initial testify. Under the editorship which the third edition has enjoyed, the work is sure to sustain its good reputation, and to maintain its usefulness.—*N. Y. Med. Journ.*, Jan. 1881.

There is really no work which approaches it in adaptation to the wants of the general practitioner, while the most advanced specialist cannot rise from a perusal of its ample pages without having added to his knowledge. The American editor, Dr. Bull, won his spurs in ophthalmology some time back. His additions to the work of the lamented Wells are many, judicious, and timely, and in just so much have added to its value.—*Am. Practitioner*, Jan. 1881.

NETTLESHIP (*EDWARD*), *F.R.C.S.*,
Ophthalmic Surg. and Lect. on Ophth. Surg. at St. Thomas' Hospital, London.

MANUAL OF OPHTHALMIC MEDICINE.

In one royal 12mo volume of over 350 pages, with 89 illustrations. Cloth, $2. (*Just Ready.*)

The author is to be congratulated upon the very successful manner in which he has accomplished his task; he has succeeded in being concise without sacrificing clearness, and, including the whole ground covered by more voluminous text-books, has given an excellent *résumé* of all the practical information they contain. We do not hesitate to pronounce Mr Nettleship's book the best manual on ophthalmic surgery for the use of students and "busy practitioners" with which we are acquainted.—*Am. Jour. Med. Sciences*, April, 1880.

CARTER (*R. BRUDENELL*), *F.R.C.S.*,
Ophthalmic Surgeon to St. George's Hospital, etc.

A PRACTICAL TREATISE ON DISEASES OF THE EYE.

Edited, with test-types and Additions, by JOHN GREEN, M.D. (of St. Louis, Mo.). In one handsome octavo volume of about 500 pages, and 124 illustrations. Cloth, $3 75.

It is with great pleasure that we can endorse the work as a most valuable contribution to practical ophthalmology. Mr. Carter never deviates from the end he has in view, and presents the subject in a clear and concise manner, easy of comprehension, and hence the more valuable. We would especially commend, however, as worthy of high praise, the manner in which the therapeutics of disease of the eye is elaborated, for here the author is particularly clear and practical, where other writers are unfortunately too often deficient. The final chapter is devoted to a discussion of the uses and selection of spectacles, and is admirably compact, plain, and useful, especially the paragraphs on the treatment of presbyopia and myopia. In conclusion, our thanks are due the author for many useful hints in the great subject of ophthalmic surgery and therapeutics, a field where of late years we glean but a few grains of sound wheat from a mass of chaff.—*New York Medical Record*, Oct. 23, 1875.

BROWNE (*EDGAR A.*),
Surgeon to the Liverpool Eye and Ear Infirmary, and to the Dispensary for Skin Diseases.

HOW TO USE THE OPHTHALMOSCOPE.

Being Elementary Instructions in Ophthalmoscopy, arranged for the Use of Students. With thirty-five illustrations. In one small volume royal 12mo. of 120 pages: cloth, $1.

LAURENCE'S HANDY-BOOK OF OPHTHALMIC SURGERY, for the use of Practitioners. Second edition, revised and enlarged With numerous illustrations. In one very handsome octavo volume, cloth, $2 75.

LAWSON'S INJURIES TO THE EYE, ORBIT AND EYELIDS: their Immediate and Remote Effects. With about one hundred illustrations. In one very handsome octavo volume, cloth, $3 50.

BURNETT (CHARLES H.), M.A., M.D.,

Aural Surg to the Presb. Hosp., Surgeon-in-charge of the Infir. for Dis. of the Ear, Phila.

THE EAR, ITS ANATOMY, PHYSIOLOGY AND DISEASES.

A Practical Treatise for the Use of Medical Students and Practitioners. In one handsome octavo volume of 615 pages, with eighty-seven illustrations: cloth, $4 50; leather, $5 50; half Russia, $6 00. (*Lately Issued.*)

Foremost among the numerous recent contributions to aural literature will be ranked this work of Dr. Burnett. It is impossible to do justice to this volume of over 600 pages in a necessarily brief notice. It must suffice to add that the book is profusely and accurately illustrated, the references are conscientiously acknowledged, while the result has been to produce a treatise which will henceforth rank with the classic writings of Wilde and Von Tröltsch.—*The Lond. Practitioner*, May, 1879.

On account of the great advances which have been made of late years in otology, and of the increased interest manifested in it, the medical profession will welcome this new work, which presents clearly and concisely its present aspect, whilst clearly indicating the direction in which further researches can be most profitably carried on. Dr. Burnett from his own matured experience, and availing himself of the observations and discoveries of others, has produced a work which, as a text-book, stands *facile princeps* in our language. We had marked several passages as well worthy of quotation and the attention of the general practitioner, but their number and the space at our command forbid. Perhaps it is better, as the book ought to be in the hands of every medical student, and its study will well repay the busy practitioner in the pleasure he will derive from the agreeable style in which many otherwise dry and mostly unknown subjects are treated. To the specialist the work is of the highest value, and his sense of gratitude to Dr. Burnett will, we hope, be proportionate to the amount of benefit he can obtain from the careful study of the book, and a constant reference to its trustworthy pages.—*Edinb. Jl Med. Jour.*, Aug. 1878.

TAYLOR (ALFRED S.), M.D.,

Lecturer on Med. Jurisp. and Chemistry in Guy's Hospital.

A MANUAL OF MEDICAL JURISPRUDENCE. Eighth American edition.

Thoroughly revised and rewritten. Edited by JOHN J. REESE, M.D., Prof. of Med. Jurisp. and Toxicology in the Univ. of Penn. In one large octavo volume of 933 pages, with 70 illustrations. Cloth, $5; leather, $6; half Russia, raised bands, $6 50. (*Just Ready.*)

The American editions of this standard manual have for a long time laid claim to the attention of the profession in this country; and that the profession has recognized this claim with favor is proven by the call for frequent new editions of the work. This one, the eighth, comes before us as embodying the latest thoughts and emendations of Dr. Taylor, upon the subject to which he devoted his life, with an assiduity and success which made him *facile princeps* among English writers on medical jurisprudence. Both the author and the book have made a mark too deep to be affected by criticism, whether it be censure or praise. In this case, however, we should only have to seek for laudatory terms.—*Am. Journ. of Med. Sci.*, Jan. 1881.

It is not very often that a medical book reaches its tenth edition, or that the last earthly labor is performed by the author in retouching the work that first came from his hand thirty-five years before. All this, however, has happened in the case of Dr. Taylor and his classical treatise. The pen dropped from the grasp only when the shadows of old age were rapidly deepening into the darkness of death. Under the circumstances, all the journalist has to do is to announce, not criticize, the completed task. The value of the gem is too well known to require more than the telling that the master-hand has refrightened its facets and polished its angles before leaving it as his legacy to his brethren in the profession.—*Phila Med. Times*, Dec. 4, 1880.

It will suffice to remark that this new edition shows the signs of judicious revision. A great number of illustrative medico-legal cases which have occurred since the last edition was published are cited in their proper connection, and add much to the interest and value of the work; they comprise the bulk of the additions to the text. As an indication of the freshness of the work, we notice numerous references to medico-legal experience that has transpired during the year just ended; among these is a comment by the American editor upon that midsummer madness, the Tanner fasting exploit of last August. In these features and in others there is ample evidence that this admirable book will maintain its high place as a standard authority concerning the matters of which it treats.—*Boston Med. and Surg. Journal*, Jan. 13, 1881.

BY THE SAME AUTHOR.

THE PRINCIPLES AND PRACTICE OF MEDICAL JURISPRUDENCE.

Second Edition, Revised, with numerous Illustrations. In two large octavo volumes, cloth, $10 00; leather, $12 00

This great work is now recognised in England as the fullest and most authoritative treatise on every department of its important subject. In laying it, in its improved form, before the American profession, the publishers trust that it will assume the same position in this country.

BY THE SAME AUTHOR.

POISONS IN RELATION TO MEDICAL JURISPRUDENCE AND MEDICINE.

Third American, from the Third and Revised English Edition. In one large octavo volume of 850 pages; cloth, $5 50; leather, $6 50.

The present is based upon the two previous editions; "but the complete revision rendered necessary by time has converted it into a new work." This statement from the preface contains all that it is desired to know in reference to the new edition. The works of this author are already in the library of every physician who is liable to be called upon for medico-legal testimony (and what one is not?), so that all that is required to be known about the present book is that the author has kept it abreast with the times. What makes it now, as always, especially valuable to the practitioner is its conciseness and practical character, only those poisonous substances being described which give rise to legal investigations.—*The Clinic*, Nov. 6, 1875.

Dr. Taylor has brought to bear on the compilation of this volume, stores of learning, experience, and practical acquaintance with his subject, probably far beyond what any other living authority on toxicology could have amassed or utilized. He has fully sustained his reputation by the consummate skill and legal acumen he has displayed in the arrangement of the subject-matter, and the result is a work on Poisons which will be indispensable to every student or practitioner in law and medicine.—*The Dublin Journ. of Med Sci.*, Oct. 1875.

ROBERTS (WILLIAM), M.D.,

Lecturer on Medicine in the Manchester School of Medicine, &c.

A PRACTICAL TREATISE ON URINARY AND RENAL DISEASES, including Urinary Deposits. Illustrated by numerous cases and engravings. Third American, from the Third Revised and Enlarged London Edition. In one large and handsome octavo volume of over 600 pages. Cloth, $4. (*Just Ready.*)

THOMPSON (SIR HENRY),

Surgeon and Professor of Clinical Surgery to University College Hospital.

LECTURES ON DISEASES OF THE URINARY ORGANS. With illustrations on wood. Second American from the Third English Edition. In one neat octavo volume. Cloth, $2 25.

BY THE SAME AUTHOR.

ON THE PATHOLOGY AND TREATMENT OF STRICTURE OF THE URETHRA AND URINARY FISTULÆ. With plates and wood-cuts. From the third and revised English edition. In one very handsome octavo volume, cloth, $3 50.

TUKE (DANIEL HACK), M.D.,

Joint author of The Manual of Psychological Medicine, &c.

ILLUSTRATIONS OF THE INFLUENCE OF THE MIND UPON THE BODY IN HEALTH AND DISEASE. Designed to illustrate the Action of the Imagination. In one handsome octavo volume of 416 pages, cloth, $3 25.

BLANDFORD (G. FIELDING), M.D., F.R.C.P.,

Lecturer on Psychological Medicine at the School of St. George's Hospital, &c.

INSANITY AND ITS TREATMENT: Lectures on the Treatment, Medical and Legal, of Insane Patients. With a Summary of the Laws in force in the United States on the Confinement of the Insane. By ISAAC RAY, M. D. In one very handsome octavo volume of 471 pages; cloth, $3 25.

It satisfies a want which must have been sorely felt by the busy general practitioners of this country. It takes the form of a manual of clinical description of the various forms of insanity, with a description of the mode of examining persons suspected of insanity. We call particular attention to this feature of the book, as giving it a unique value to the general practitioner. If we pass from theoretical considerations to descriptions of the varieties of insanity as actually seen in practice and the appropriate treatment for them, we find in Dr. Blandford's work a considerable advance over previous writings on the subject. His pictures of the various forms of mental disease are so clear and good that no reader can fail to be struck with their superiority to those given in ordinary manuals in the English language or (so far as our own reading extends) in any other.—*London Practitioner*, Feb. 1871.

LEA (HENRY C.).

SUPERSTITION AND FORCE: ESSAYS ON THE WAGER OF LAW, THE WAGER OF BATTLE, THE ORDEAL AND TORTURE. Third Revised and Enlarged Edition. In one handsome royal 12mo. volume of 552 pages. Cloth, $2 50. (*Just Ready.*)

This valuable work is in reality a history of civilization as interpreted by the progress of jurisprudence. . . . In "Superstition and Force" we have a philosophic survey of the long period intervening between primitive barbarity and civilized enlightenment. There is not a chapter in the work that should not be most carefully studied, and however well versed the reader may be in the science of jurisprudence, he will find much in Mr. Lea's volume of which he was previously ignorant. The book is a valuable addition to the literature of social science.—*Westminster Review*, Jan. 1880.

The appearance of a new edition of Mr. Henry C. Lea's "Superstition and Force" is a sign that our highest scholarship is not without honor in its native country. Mr. Lea has met every fresh demand for his work with a careful revision of it, and the present edition is not only fuller and, if possible, more accurate than either of the preceding, but, from the thorough elaboration, is more like a harmonious concert and less like a batch of studies.—*The Nation*, Aug. 1, 1878.

Many will be tempted to say that this, like the "Decline and Fall," is one of the uncriticizable books. Its facts are innumerable, its deductions simple and inevitable, and its *chevaux-de-frise* of references bristling and dense enough to make the keenest, stoutest, and best equipped assailant think twice before advancing. Nor is there anything controversial in it to provoke assault. The author is no polemic. Though he obviously feels and thinks strongly, he succeeds in attaining impartiality. Whether looked on as a picture or a mirror, a work such as this has a lasting value.—*Lippincott's Magazine*, Oct. 1878.

BY THE SAME AUTHOR.

STUDIES IN CHURCH HISTORY. THE RISE OF THE TEMPORAL POWER—BENEFIT OF CLERGY—EXCOMMUNICATION. In one large royal 12mo. volume of 516 pp.; cloth, $2 75. (*Lately Published.*)

The story was never told more calmly or with greater learning or wiser thought. We doubt, indeed, if any other study of this field can be compared with this for clearness, accuracy, and power.—*Chicago Examiner*, Dec. 1870.

Mr. Lea's latest work, "Studies in Church History," fully sustains the promise of the first. It deals with three subjects—the Temporal Power, Benefit of Clergy, and Excommunication, the record of which has a peculiar importance for the English student, and is a chapter on Ancient Law likely to be regarded as final. We can hardly pass from our mention of such works as these—with which that on "Sacerdotal Celibacy" should be included—without noting the literary phenomenon that the head of one of the first American houses is also the writer of some of its most original books.—*London Athenæum*, Jan. 7, 1871.

STANDARD MEDICAL TEXT-BOOKS.

GYNÆCOLOGY AND OBSTETRICS.

THOMAS ON THE DISEASES OF WOMEN. Fifth edition, thoroughly revised and rewritten. In one handsome 8vo. volume of over 800 pages, with 266 illustrations. Cloth, $5; leather, $6; half Russia, raised bands, $6.50.

EMMET'S PRINCIPLES AND PRACTICE OF GYNÆCOLOGY. Second edition, thoroughly revised. In one handsome 8vo. volume of 875 pages, with 133 illustrations. Cloth, $5; leather, $6; half Russia, raised bands, $6.50.

BARNES ON THE MEDICAL AND SURGICAL DISEASES OF WOMEN. Second American from the Second revised English edition. In one handsome 8vo. volume of 784 pages, with 181 illustrations. Cloth, $4 50; leather, $5.50; half Russia, raised bands, $6.

LEISHMAN'S SYSTEM OF MIDWIFERY. Third American edition, with additions by John S. Parry, M.D. In one handsome 8vo volume of 733 pages, with over 200 illustrations. Cloth, $4.50; leather, $5.50. half Russia, raised bands, $6.

PLAYFAIR'S SCIENCE AND PRACTICE OF MIDWIFERY. Third American edition, with additions by R. P. Harris, M.D. In one handsome 8vo. volume of about 700 pages, with nearly 200 illustrations. Cloth, $4; leather, $5; half Russia, raised bands, $5.50.

RAMSBOTHAM'S PRINCIPLES AND PRACTICE OF OBSTETRIC MEDICINE AND SURGERY. In one imperial 8vo. volume of 650 pages, with 64 plates and numerous engravings. Leather, $7.

SURGERY.

BRYANT'S PRACTICE OF SURGERY. Third American from the Second English edition. Thoroughly revised and enlarged by Jno. B. Roberts, M.D. In one handsome imperial 8vo. volume of over 1000 pages, with 672 illustrations. Cloth, $6.50; leather, $7.50; half Russia, raised bands, $8.

GROSS'S SYSTEM OF SURGERY. Fifth edition, carefully revised and improved. In two imperial 8vo. volumes of about 2300 pages, with about 1400 engravings. Leather, raised bands, $15; half Russia, raised bands, $16.

ERICHSEN'S SCIENCE AND ART OF SURGERY. Carefully revised by the author from the Seventh English edition. In two large 8vo. volumes of nearly 2000 pages, with 862 illustrations. Cloth, $8.50; leather, $10.50; half Russia, raised bands, $11.50.

HOLMES'S SYSTEM OF SURGERY. In treatises by various authors. First American from the Second English edition. Thoroughly revised and with extensive additions by J. H. Packard, M.D, assisted by thirty-two of the most eminent American surgeons. In three imperial 8vo. volumes of about 3000 pages, with about 1000 engravings and 18 colored plates. Per volume, cloth, $6; leather, $7; half Russia, $7.50. Vol. I. (*Just Ready*). (Vols. II. and III. *Shortly.*)

HOLMES'S SURGERY. Its Principles and Practice. In one handsome 8vo. volume of nearly 1000 pages, with 411 illustrations. Cloth, $6; leather, $7; half Russia, raised bands, $7.50.

ASHHURST'S PRINCIPLES AND PRACTICE OF SURGERY. Second edition. In one 8vo. volume of over 1000 pages, with 542 illustrations. Cloth, $6; leather, $7; half Russia, raised bands, $7.50.

STIMSON'S MANUAL OF OPERATIVE SURGERY. In one royal 12mo. volume of about 500 pages, with 332 illustrations. Cloth, $2.50.

DRUITT'S PRINCIPLES AND PRACTICE OF MODERN SURGERY. From the Eighth English edition. In one 8vo. volume of nearly 700 pages, with 432 engravings. Cloth, $4; leather, $5.

MANUALS.

DUNGLISON'S MEDICAL LEXICON. New edition, thoroughly revised and greatly modified and augmented by R. J. Dunglison, M.D. In one large and handsome 8vo. volume of over 1100 pages. Cloth, $6.50; leather, $7.50; half Russia, raised bands, $8.

HOBLYN'S MEDICAL DICTIONARY. Revised, with numerous additions by Isaac Hays, M.D. In one royal 12mo. volume of over 500 double-columned pages. Cloth, $1 50; leather, $2.

HARTSHORNE'S CONSPECTUS OF THE MEDICAL SCIENCES. Second edition, thoroughly revised and much improved. In one royal 12mo. volume of more than 1000 pages, with 477 illustrations. Cloth, $4.25; leather, $5.

NEILL AND SMITH'S ANALYTICAL COMPENDIUM OF THE VARIOUS BRANCHES OF MEDICAL SCIENCE. Second edition. In one royal 12mo. volume of about 1000 pages, with 374 illustrations. Cloth, $4; leather, $4.75.

LUDLOW'S MANUAL OF EXAMINATIONS. Third edition. In one royal 12mo. volume of 816 pages, with 370 illustrations. Cloth, $3 25; leather, $3.75.

FINLAYSON'S CLINICAL DIAGNOSIS. A Handbook for Students and Practitioners of Medicine. In one royal 12mo. volume of 546 pages, with 85 illustrations. Cloth, $2.63.

FENWICK'S STUDENT'S GUIDE TO MEDICAL DIAGNOSIS. From the Third revised English edition. In one royal 12mo. volume of 328 pages, with 84 illustrations. Cloth, $2.25.

FLINT ON PERCUSSION AND AUSCULTATION. Second edition. In one 12mo. volume. Cloth, $1.63.

MEDICAL JURISPRUDENCE.

TAYLOR'S MANUAL OF MEDICAL JURISPRUDENCE. Eighth American edition, thoroughly revised and rewritten, with additions by J. J. Reese, M.D. In one 8vo. volume of 933 pages, with 70 illustrations. Cloth, $5; leather, $6; half Russia, raised bands, $6.50.

TAYLOR ON POISONS IN RELATION TO MEDICAL JURISPRUDENCE AND MEDICINE. Third American from Third revised English edition. In one 8vo. volume of 860 pages. Cloth, $5.50; leather, $6.50.

HENRY C. LEA'S SON & CO.—Philadelphia.

PROSPECTUS FOR 1881.

THE AMERICAN JOURNAL OF THE MEDICAL SCIENCES.

In commencing its sixty-first year, the publishers of the "AMERICAN JOURNAL OF THE MEDICAL SCIENCES" have much pleasure in assuring its wide circle of readers that at no period has it had the prospect of a more extended field of usefulness.

For 1881 the "American Journal" has the promise of its usual variety of important contributions from distinguished members of the profession in all parts of the country. Special attention will be bestowed, as heretofore, on its Bibliographical Department and Quarterly Summaries to keep its subscribers informed as to all subjects of professional interest from every quarter.

With its attendant periodical, "THE MEDICAL NEWS AND ABSTRACT," it combines the advantages of the elaborate preparation which can be given to a quarterly, and the prompt conveyance of intelligence by the monthly, while, the whole being under a single editorial supervision, the subscriber is secured against the duplication of matter inevitable under other circumstances. These efforts the publishers seek to second by offering these periodicals at a price unprecedentedly low—a price which places them within the reach of every practitioner, and gives the equivalent of three large octavo volumes for the comparatively trifling cost of FIVE DOLLARS *per annum*.

The "NEWS AND ABSTRACT" consists of sixty-four pages monthly, in a neat cover. It contains a CLINICAL DEPARTMENT in which will be continued the series of ORIGINAL AMERICAN CLINICAL LECTURES, contributed by gentlemen of the highest reputation throughout the United States, together with a choice selection of Foreign Lectures and Hospital Notes and Gleanings. Then follows the "MONTHLY ABSTRACT," systematically arranged and classified, and presenting five or six hundred articles yearly; each number concluding with an EDITORIAL and a NEWS DEPARTMENT, giving current professional intelligence, domestic and foreign, the whole fully indexed at the close of each volume, rendering it of permanent value for reference.

The subscription price to the "NEWS AND ABSTRACT" will be Two Dollars and a Half per annum, invariably in advance, at which rate it will rank as one of the cheapest medical periodicals in the country. But it will also be furnished, free of all charge, in commutation with the "AMERICAN JOURNAL OF THE MEDICAL SCIENCES," to all who remit FIVE DOLLARS in advance, thus giving to the subscriber, for that very moderate sum, a complete record of medical progress throughout the world, in the compass of about two thousand large octavo pages.

These terms may be recapitulated as follows:—

TERMS FOR 1881.

The AMERICAN JOURNAL OF THE MEDICAL SCIENCES, published quarterly (1150 pages per annum), and
The MEDICAL NEWS AND ABSTRACT, published monthly (768 pages per annum), } Five Dollars per annum, in advance.

SEPARATE SUBSCRIPTIONS TO

The AMERICAN JOURNAL OF THE MEDICAL SCIENCES, when not paid for in advance, } Five Dollars.
The MEDICAL NEWS AND ABSTRACT, invariably in advance, Two Dollars and a Half.

*** Advance-paying subscribers can obtain, at the close of the year, cloth covers, gilt lettered, for binding the volumes of the JOURNAL (two annually) and the NEWS AND ABSTRACT (one annually), free by mail, on remitting ten cents for each cover.

The safest mode of remittance is by bank check or draft, or postal money order drawn to the order of the undersigned. Where these are not accessible, remittances for the "JOURNAL" and "NEWS AND ABSTRACT" may be made at the risk of the publishers by forwarding in REGISTERED letters. Address

THE

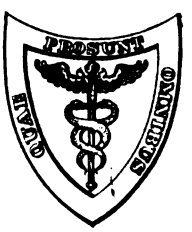
MEDICAL NEWS

AND

ABSTRACT.

EDITED BY

I. MINIS HAYS, A.M., M.D.



PHILADELPHIA:
HENRY C. LEA'S SON & CO.
1881.

PUBLISHED MONTHLY AT $2.50 PER ANNUM IN ADVANCE.
Furnished in conjunction with the Quarterly American Journal of the Medical Sciences (in all nearly 2000 octavo pages) for $5.00 in advance.

Entered according to the Act of Congress, in the year 1881, by HENRY C. LEA'S SON & Co., in the Office of the Librarian of Congress. All rights reserved.

FLINT'S PRACTICE—New Edition—Just Ready.

A TREATISE ON THE PRINCIPLES AND PRACTICE OF MEDICINE; Designed for the use of Students and Practitioners of Medicine. By AUSTIN FLINT, M.D., Professor of the Principles and Practice of Medicine in Bellevue Med. College, N. Y. Fifth edition, thoroughly revised and much improved. In one large and closely printed octavo volume of 1153 pages. Cloth, $5 50; leather, $6 50; very handsome half Russia, raised bands, $7.

This work has been so long and favorably known, and has obtained so high a position amongst modern treatises on medicine, that it is hardly necessary to do more than announce the publication of this fifth edition. All who peruse it must be struck by the extensive research which has been undertaken in the revision of this edition, combined with much original thought. There is hardly a subject which does not receive fresh illustration and discussion, opening up new lines of inquiry which had not been thought of when the previous edition appeared. We cannot conclude this notice without expressing our admiration for this volume, which is certainly one of the standard text books on medicine, and we may safely affirm that, taken altogether, it exhibits a fuller and wider acquaintance with recent pathological inquiry than any similar work with which we are acquainted, whilst at the same time it shows its author to be possessed of the rare faculties of clear exposition, thoughtful discrimination, and sound judgment.—*London Lancet*, July 23, 1881.

GRAY'S ANATOMY—Now Ready,

ANATOMY, DESCRIPTIVE AND SURGICAL. By HENRY GRAY, F.R S, Lecturer on Anatomy at St. George's Hospital, London. The drawings by H. V. CARTER, M.D., and Dr. WESTMACOTT. The dissections jointly by the author and Dr. CARTER. With an Introduction on General Anatomy and Development by T. HOLMES, M.A., Surgeon to St. George's Hospital. A new American, from the eighth enlarged and improved London edition. To which is added the second American, from the third English edition of "LANDMARKS, MEDICAL AND SURGICAL, by LUTHER HOLDEN, F.R.C.S, author of "Human Osteology," "A Manual of Dissections," etc. With additions by W. W. KEEN, M.D., formerly Lecturer on Anatomy in the Phila. School of Anatomy. In one magnificent imperial octavo volume of 983 pages, with 522 large and elaborate engravings. Cloth, $6; leather, raised bands, $7; very handsome half Russia, raised bands, $7 50.

The recent work of Mr. Holden has been added as an appendix, so that, altogether, this is the most practical and complete anatomical treatise available to American students and physicians. The former find in it the necessary guide in making dissections; a very comprehensive chapter on minute anatomy; and about all that can be taught him on general and special anatomy; while the latter, in its treatment of each region from a surgical point of view, and in the valuable addition of Mr. Holden, will find all that will be essential to him in his practice.—*New Remedies*, Aug. 1878.

THE NATIONAL DISPENSATORY—Second Edition—Now Ready.

THE NATIONAL DISPENSATORY, CONTAINING THE NATURAL HISTORY, CHEMISTRY, PHARMACY, ACTIONS AND USES OF MEDICINES, including those recognized in the Pharmacopœias of the United States, Great Britain, and Germany, with numerous references to the French Codex. By ALFRED STILLÉ, M.D., LL.D., Prof. of the Theory and Practice of Medicine and of Clinical Medicine in the Univ. of Penna., and JOHN M. MAISCH, Ph.D., Prof. of Mat. Medica and Botany in the Phila. Coll. of Pharmacy, Secy. to the Am. Pharmaceutical Association. Second edition, thoroughly revised, with numerous additions. In one very handsome octavo volume of sixteen hundred and ninety-two pages, with two hundred and thirty-nine illustrations. Extra cloth, $6 75; leather, raised bands, $7 50; half Russia, raised bands and open back, $8 25.

This evidence of success, seldom paralleled, shows clearly how well the authors have met the existing needs of the pharmaceutical and medical professions. Gratifying as it must be to them, they have embraced the opportunity offered for a thorough revision of the whole work, striving to embrace within it all that might have been omitted in the former edition, and all that has newly appeared of sufficient importance during the time of its collaboration, and the short interval elapsed since the previous publication. After having gone carefully through the volume we must admit that the authors have labored faithfully, and with success, in maintaining the high character of their work as a compendium meeting the requirements of the day, to which one can safely turn in quest of the latest information concerning everything worthy of notice in connection with Pharmacy, Materia Medica, and Therapeutics.—*Am. Journ. of Pharmacy*, Nov. 1879.

DUNGLISON'S MEDICAL DICTIONARY—Lately Issued.

MEDICAL LEXICON; A DICTIONARY OF MEDICAL SCIENCE: Containing a concise explanation of the various subjects and terms of Anatomy, Physiology, Pathology, Hygiene, Therapeutics, Pharmacology, Pharmacy, Surgery, Obstetrics, Medical Jurisprudence and Dentistry, Notices of Climate and of Mineral Waters; Formulæ for Officinal, Empirical and Dietetic Preparations; with the Accentuation and Etymology of the Terms, and the French and other Synonymes, so as to constitute a French as well as English Medical Lexicon. By ROBLEY DUNGLISON, M.D, late Prof. of Institutes of Medicine in Jefferson Medical College, Philadelphia. A new edition, thoroughly revised and very greatly modified and augmented. By RICHARD J. DUNGLISON, M.D. In one very large and handsome royal octavo volume of over 1100 pages. Cloth, $6 50; leather, raised bands, $7 50; half Russia, $8.

About the first book purchased by the medical student is the Medical Dictionary. The lexicon explanatory of technical terms is simply a *sine qua non*. In a science so extensive, and with such collaterals as medicine, it is as much a necessity also to the practising physician. To meet the wants of students and most physicians, the dictionary must be condensed while comprehensive, and practical while perspicacious. It was because Dunglison's met these indications that it became at once the dictionary of general use wherever medicine was studied in the English language. In no former revision have the alterations and additions been so great. More than six thousand new subjects and terms have been added. The chief terms have been set in black letter, while the derivatives follow in small caps; an arrangement which greatly facilitates reference. We may safely confirm the hope ventured by the editor "that the work, which possesses for him a filial as well as an individual interest, will be found worthy a continuance of the position so long accorded to it as a standard authority."—*Cincinnati Clinic*, Jan. 10, 1874.

THE RELATION OF CLEANLINESS TO THE PREVENTION OF PUERPERAL SEPTICÆMIA.

A CLINICAL LECTURE.

BY ALBERT H. SMITH, M.D.,

LECTURER ON PRACTICAL OBSTETRICS TO THE PHILADELPHIA LYING-IN CHARITY.

ONE of the greatest steps in the progress of modern obstetrics is the full recognition, which has at last been brought about, of the causal relations of septic absorption to the great train of inflammatory and febrile troubles, attendant upon the puerperal condition, and upon the after stage of abortion, embracing those fearfully fatal maladies which have, since obstetrics could be considered to be an art, been the opprobrium of that department of medicine. When we bear in mind that the process of parturition is simply a physiological one; that it is to a human being what the ripening and falling off of the fruit is to the tree; that it is really but a natural function of the reproductive organs, and ought not to be attended with any more danger than the functional operation of any other organs, provided the mother be placed in circumstances favourable for the free course of nature's laws;—we find it a lamentable thing, surely, and a source of the deepest humiliation, that there can arise in the newly delivered woman, a disease, whose source we cannot trace, whose outburst we cannot anticipate, whose course we cannot control; further and more deplorable, that the disease may attack the healthiest, the most robust, the most buoyant, the woman of best previous condition for health, the woman surrounded by the most favourable relations for resisting pestilence, the woman with everything to live for and everything to make her live; that it converts the simple physiological process, which nature ought to guarantee and protect against danger, into a cause of agonizing death, and into the house where the highest joys of life have just been realized, brings, as it were in an instant, the deepest grief and desolation.

We cannot wonder, then, that for ages the teachers and practitioners of the obstetric art should have felt this reproach and bestirred themselves earnestly to remove it. And, we find upon this one subject continuous discussion and the arising from time to time of opposing schools as to the causations and the treatment of this fearful scourge, each school making

an honest and conscientious effort to get at the true cause from its own stand-point of observation, and each founding its treatment upon reasonable deductions from its views of the pathological conditions. We have had in turn the earnest partisans of the doctrine of acute inflammation, of specific fever, of contagion, of epidemic influence, of typhus, and of thrombosis; and the appropriate treatment insisted upon for each. But the true causation of the puerperal diseases was first suggested by Semmelweiss, as being the absorption from open surfaces of decayed animal matter, resulting in a true blood-poisoning, operating either by the production of an erysipelatous inflammation at the point of absorption and gradually travelling to adjacent tissues, and secondarily through the lymphatics and by blood-infection producing a blood-phlogosis and death; or, when the poison was exceedingly virulent being carried by absorption directly into the blood without the previous, or even intercurrent, development of any local phlegmasia, going on to rapid blood-disorganization and death. In other words, he announced the theory that all puerperal fevers, peritonitis, arthritis, cellulitis, and the whole range of those serious lesions appearing a few days after labour, attended by high temperature, increased pulse rate, and various local inflammations, are merely different forms and manifestations of one and the same pathological condition, and that that was septicæmia. The profession, especially the English and the American teachers, were slow in adopting this view, but it has now become so thoroughly proven by clinical observation, and comparative symptomatology, that but little opposition is made to its recognition. It is agreed then at present that these diseases are precisely analogous in their causation, their pathology, their course of development, their urgent need of prophylaxis, and their treatment, to septic inflammation and fever found in surgical practice, their differences dependent only upon the peculiarity of the tissues involved in parturition, upon their exceeding capacity for absorption and transfer of poison, and upon the many points likely to be presented where such absorption may take place.

Another consideration in connection with these diseases, is the vastly greater number of cases needing care than in any other class of practice; also the greater number of sources from whence the poison may be accidentally conveyed to the absorbing surfaces; also, lastly, the greater caution to be used in watching against accidental or thoughtless conveyance from such sources. It is upon this last point which I wish mainly to dwell in this lecture, that is, upon what is called the antiseptic management of labour and the puerperium, the prophylaxis of septicæmia, which, as in all other antiseptic treatment, means simply the maintenance of cleanliness, as far as possible absolutely, in opened surfaces, until they have either united or granulated.

How to keep the genital canal clean during and after parturition is then the great question in the prevention of this horrible malady. The study of this question involves the consideration of the points where absorption may take place, the sources from whence poison may be conveyed, and the precautions to be used against such conveyance.

First, then, as to the points liable to absorb poison. We know that any surface upon which there is loss of integrity of the external investment (whether epidermis upon the integument, or epithelium upon the mucous membrane) is capable of absorption; and we know well how a very slight opening into the integument upon the hands, a scratch, of which one was not even conscious before, will smart when introduced into any

acrid liquid, or may absorb the fatal poison from the cadaver when it was not even suspected. How much more then might we expect, upon theoretical grounds, that the highly vascular tissues of the genital canal, as we find them in their increased vitality in pregnancy and even more especially during parturition, would be quick to take up any noxious material which comes in contact with fissures or abrasions upon their surfaces; and unfortunately our practical experience gives sad confirmation of the theory. We know how, even in the unimpregnated uterus, the gentlest use of a mechanical dilator may lacerate the mucous surface of the cervix, producing, perhaps, tears that the naked eye could scarcely detect; and we know so well, if any broken-down or decaying tissue from a malignant growth or from the scraping of vegetations, so often recklessly done, should come into contact with this point of opening, how a fire is lighted up, and we are startled by the outbreak of a series of symptoms, the meaning of which we know so well: the high temperature, and the rapid pulse, and the quickened respiration, and then the pain and the tenderness—pelvic and abdominal—and the chill, and the other evidences of the septic metritis, and cellulitis and parametric phlegmon, and, perhaps, peritonitis and death. And yet in the process of labour, we have not only the little fissure to absorb, but also, especially in the primipara, large open surfaces, superadded often one upon another, from the cervical canal to the integument of the perineum. Now these are altogether unavoidable to a large extent; in a greater or less degree we may consider that they are present in every case of labour. There is probably not one case in a thousand in which there is not before the process is completed some solution of continuity. This may occur very superficially without any bleeding, but when there is blood there must necessarily be a surface to bleed, and how very rare is it to go through the management of a case where there is no stain of blood before the head is expelled. The "show," that is, the plug of tinged mucus, which sometimes and often amounts to a free discharge of blood, is recognized by the monthly nurse as the diagnostic sign that labour has begun, so uniformly is this present.

This, then, is the beginning of the lacerations, and the first appearance of blood in normal labour, or when there is no premature placental detachment, or mis-implantation of that organ. This discharge arises, undoubtedly, from the rupture of some minute fibres of the uterine lower segment, probably in the expansion of the internal os, as the contractions of this body drive the membranous pouch or the presenting part of the child into it, at the same time loosening up the plug of cervical mucus, which comes away stained with the momentary discharge from the lacerated surface. How far this continues to tear, we cannot say, but I have no doubt that fissures in the canal are much more frequent than we have any positive means of proving, for we often have free, and even profuse, bleedings from the cervix after the expulsion of the placenta, when no fissure in the rim of the os can be detected, yet the firm contraction of the uterine body and the bright red colour of the flow, and sometimes even the arterial jet, show that it cannot come from patulous venous sinuses opening upon the placental site. There is no blood from these tears while the head is passing, because the compression of the surface then prevents it. As the distension goes on, just before the os is fully open, a violent expulsive effort will often drive the presenting part of the child so forcibly, that the most prominent projection upon the circumference of the head-globe, making a sudden strain upon the rim, where it impinges, will tear

through, either in the line of a fissure already made, or, starting an entirely new laceration, until a gap is produced involving the whole distance from the rim to the vaginal reflection. And then, after the head has cleared the os uteri, and meets the resistance of an undilatable canal, and especially in the posterior occipital position, when the forced flexion drives the occiput at each recurring pain violently against the posterior vaginal wall, how often does the finger detect the opening of a little fissure upon the mucous surface, as the head recedes after the subsidence of the pain; and with each successive pain finds the fissure deepening into a furrow, which causes the observer great anxiety for the safety of the perineal body, lest it should involve the deep tissue of the recto-vaginal septum, and unless prevented by judicious labial incisions, even cut through the perineum and the sphincter into the rectum. Then as the head passes the vulvar outlet, there may be minor separations of tissues, even if the perineum proper be saved; and sometimes when no laceration can be found upon the mucous surface, the perineal integument in the line of the raphé may yield superficially before the great tension.

Thus we see how many ways there are in which the surfaces of the parturient canal may be opened for absorption of poison, and we have in addition to all these the large placental site, covering one-fourth of the whole superficies of the uterine cavity. It will be easily recognized, why in the primipara, with her rigid tissues never before subjected to dilatation and strain, the probabilities will be vastly greater of vaginal and vulvar, and somewhat greater of cervical, laceration, than in the pluripara, with her previous distension.

Having now considered briefly the causes and the character of the various absorbing surfaces in the lying-in woman, let us call to mind the sources from whence poison may come. The septic diseases of childbed have been divided into *autogenetic* and *heterogenetic*, more for the ease of mind of the accoucheur than from any real distinction in the nature of the poison or of the results that attend its absorption. The autogenetic infections are those which originate from the absorption of poison generated in the body of the mother; the heterogenetic, those in which the septic matter is conveyed to the maternal tissues from extraneous sources through the neglect or ignorance of the accoucheur or the nurse.

From her own fluids the mother may be infected during her labour, when she has been the subject of any disease of her uterine or vaginal canal, attended by a discharge or casting-off of broken-down or sloughing tissue; a scirrhus or epithelioma which has undergone softening within the cervix, upon its external surface, or anywhere in the vaginal canal, or upon the vulva, where the discharge may come in contact with any open surface or point; a polypus or other non-malignant growth, from whose surface there may be a discharge, or which may be caused to slough from pressure in labour; and, more commonly, any ulcerated surface or erosion upon the cervix or vagina, discharging pus or a muco-purulent discharge, which, if allowed to remain in the vagina for any length of time, becomes virulently poisonous.

There is another autogenetic source of infection during the process of parturition, to which, as far as I know, attention has never been called, and yet, which I doubt not, is one of the most fertile causes of septic fever in cases of prolonged labour. This is the accumulation and continued exposure to atmospheric influence in contact with the warm tissues of the mother, of the *natural and healthy discharge* of mucus with its admix-

ture of blood from the cervix and vagina, while the tissues are gradually relaxing for the passage of the child. This discharge, perfectly healthy and clean, as it exudes from the vaginal canal, bathes the vulva and perineum, and the thighs and pubic region; it agglutinates the tissues, matting up in thick adhesive masses upon the labial surfaces, as can be seen when the patient is cleansed after her labour, if it has not been scrupulously cleansed before, requiring vigorous efforts with soap and water to remove it. It remains exposed to the warm air of the chamber upon the warm surface of the body. Decay, with its resulting sepsis, must soon, under these circumstances, begin its work, and the poisoned moisture outside will readily impart its virulence to the fluids of the lower vagina, and as the head passes through the vaginal canal making its attacks upon the natural barriers provided against infection, and opening one or many doors for the enemy to enter, it is there in full force prepared to insinuate itself into tissues well prepared by their unusual vitality and turgescence to receive it.

Of the autogenetic causes acting after parturition is over, the main source of infection will be the decomposition of the lochial discharge or of clots of blood or pieces of membrane retained in the uterus from deficient cleaning after labour, or from defective involution. This source will, probably, rarely be a fruitful one upon the cervical or vaginal lacerations, for these will begin to suppurate and granulate in their effort at repair in from twenty-four to thirty-six hours (unless made to unite by sutures), and up to that time the lochial discharge rarely becomes foul or likely to infect. After granulation begins there is no absorption, so that it could only be by a re-opening through some disturbance of the granulating surface, such as might occur from the passage of a large clot through the now contracted vagina, or even the presence of large, hard, fecal masses in the lower rectum. But we may easily have, as we can often recognize, septic fever developed by the absorption of poisoned lochia, or of decomposing clots pent up within the uterine cavity, through the imperfectly closed orifices of vessels opening upon the placental site of the too slowly involuted womb. The poisoning from the amniotic fluid from around a dead fœtus is so questionable as to its occurrence that it is scarcely worth while to mention it.

The *heterogenetic* sources of infection will be found in poisonous matter conveyed by the hand or the clothing upon the arm (either an enveloping towel or sleeve) either of the doctor or nurse, or upon the surface of the instruments used either during or after labour. Upon the hands of the accoucheur may be carried any septic matter with which they have come in contact, even for several days, unless care be taken with such methods of cleansing as will be suggested hereafter. The worst and most rapidly violent poisons are those from the autopsies or manipulations of tissues of persons dead with blood-diseases; but any autopsies, or handling of pathological specimens or decaying or broken-down tissues from the body living or dead ought to be avoided as death-carriers by the accoucheur, and, unless under some peculiar circumstances which might rarely render such handling necessary, ought to be conscientiously avoided. But there are equally noxious matters with which the hand of the obstetrician may be unavoidably polluted in the necessary exercise of professional duty, after contact with which the only thing is thoroughly to cleanse. Vaginal examination in cases of malignant disease, especially in operative work, when the hands are long in the vagina; examinations also of any tumours in a

sloughing condition; of a uterus dilated by tents; of any diseased conditions, even of an inflammatory character, with discharge; of simple leucorrhœa; any of these might be the source of such contagion. And especially would I caution earnestly against careless use of the hands after contact with the disorganized clots in a case of hemorrhagic abortion, the foul odour from which is as penetrating and as persistent upon the hands, and the poison as virulent, in my opinion, as that of a sloughing cancer. All discharges from wounds of the body in surgical practice should also be sedulously removed. In short, organic matter of any sort should be removed promptly and thoroughly from the hands of the obstetric practitioner, lest he should be caught with a case unexpectedly, when active detergents and disinfectants could not be obtained as quickly as an examination might be needed.

But infection may take place from the finger of the obstetrician, after the most scrupulous cleansing from any previous infection, by carelessly carrying back to the patient's person her own discharge, in the frequent examinations of a long labour. This is a point upon which I do not think any one has made suggestions, but it is easily seen that if the woman may poison herself by the retention upon her external tissues of decomposing discharges, ever so healthy at first, so may the doctor by carelessly retaining upon the hand these same fluids perfectly harmless previously, return them after they have decomposed under the nails and upon the fingers to the abraded vagina, to poison the woman whom he has been selected to protect. How often have I seen a doctor after an examination simply wipe his hands upon a towel, and make a subsequent examination without any washing in the interval.

So, also, the doctor cannot be too cautious about any sores upon the hands, or upon any part of his person with which the hands may come in contact; granular ophthalmia, otorrhœa, and what may be so easily overlooked, the discharge from a purulent coryza, or more especially from a foul ozæna. There is an historical case, to which I had better call attention in this lecture, of a physician in the early middle part of this century, who, practising in this city, was followed about from case to case almost in scores by the fearful scourge of puerperal fever, as it was then called, a man truly a "colporteur of pestilence," as Professor Schroeder would aptly have termed him; who used every means that could be thought of to cleanse his person, and to purify and regularly change his clothing, but to no effect; his touch was poison, and yet no one ever dared to suggest to him, and perhaps no one ever thought of it until too late, that the reason why his work everywhere was accompanied by the fearful disease, when other men were free from it, might be that he had a foul chronic ozæna, the thoughtless contact of his finger with which could carry poison to the tissues of his patient.

From the clothing both of the physician and nurse pestilence can be conveyed, and I would suggest that in all cases the sleeve of the doctor should be drawn up a short distance at least from the wrist and the latter closely enveloped in a napkin tightly held between the fingers and the palmar surface of the hand, and not pinned permanently. For upon the sleeve may accumulate little by little discharges from various examinations and operations, unconsciously to the physician, which when brought to lie against the mother's tissues, warm and moist, would be a fruitful source of infection. If the arm is covered with a napkin, to avoid a disagreeable impression, the sleeve may be rolled up to the elbow. But my suggestion

about the napkin not being kept permanently upon the arm during many successive examinations follows naturally upon what I had said before about the neglect to wash the hands during the intervals between the same. A towel saturated around the wrist with vaginal discharge would itself be a fertile source of infection if again brought into close proximity to the genitalia at a subsequent touch. Where at all possible, a towel even used in a lying-in chamber by the physician should be carefully put out of reach until the labour is over, or if it must be used again, thoroughly washed and disinfected in the interval. How often this is neglected by a nurse, or others in the room, a towel already soiled ever so little with blood and discharges, being handed to the accoucheur again to wipe his hands before making an examination.

Monthly nurses cannot be too scrupulous in regard to personal cleanliness in going from one case to another, and especially in going directly from the dressing of suppurating wounds or cases attended with foul discharges. In attendance upon such cases they should always wear wash dresses, and put them through the boiling process before again wearing them.

In enumerating the sources of puerperal septicæmia, I do not mean to ignore certain meteorological or atmospheric influences, present during *epidemics* of puerperal fever, so called, which predispose the patient to respond more readily to the poisonous impression of septic absorption, nor do I question the predisposing influence of malaria, and some of the eruptive fevers, to magnify such a septicæmia as in a majority of cases used to be developed upon the third day, and erroneously called *milk fever*, but which nature could often throw off unaided,—to magnify, I say, such a condition into a malignant case of septic fever, perhaps ending fatally. But I am thoroughly convinced that whatever be the predisposing condition, the immediate exciting cause of the fearful malady in all its various phases, is the absorption by open surfaces of disorganized animal matter.

It is easy to see why primiparæ are more likely to be victims to this disease than pluriparæ, when we consider the greater likelihood of injury to the mucous surface of the genital canal, the longer period of exposure of the vulvar orifice to atmospheric influence before the external surface is cleansed, and the necessity for more repeated and prolonged manipulation especially upon the perineum, in the neighbourhood of which the tissues are so very apt to be more or less impaired in their integrity.

We arrive then finally at the purpose of this lecture, to see how we can most effectually carry out that indication which must be the clear one to any mind, the PREVENTION of such poisoning; and the essential means of such prevention is *cleanliness*, the keeping clean of the tissues before and after the production of lesions of their surface, and of everything that comes in contact with them; the purifying and removal of all morbific materials, and the prevention by suitable means of their reproduction. The antiseptic treatment in surgical cases is really only a systematic method of cleanlinesss.

First, in regard to the care of the physician's person. After laying down the rule that the hands should be carefully washed and cleansed with disinfectants after handling any animal matter, I would still further say that the person of the patient should not be approached without a most thorough and complete repetition of such process, between which cleansing and the examination of the patient, nothing should be touched except what is known to be perfectly clean. No driving should be done, no

gloves worn, nothing should come in contact with the hands of a doubtful character. This cleansing should be done by soaking the hands and arms first in warm water, then with a *stiff* nail-brush with soap, scrubbing most carefully under the nails, where the poison is retained most persistently; and then the whole hands and wrists; a clean water is then to be used with the nail-brush, and the hands allowed to soak in it, medicated in the proportion of two and one-half per cent. of carbolic acid, or six to eight per cent. of good recently-made Labarraque's solution; that is about seven fluidrachms of a ninety-five per cent. solution of crystals of the former, and about a fluidounce of the latter to the pint of water. I always order as part of the preparation for labour, a bottle of each of these antiseptics to use under different conditions as may be required; and usually prepare for myself in each case, some washed lard carbolized to about five to ten per cent. The hands should be washed as directed always before the first examination, and after each examination and again before the subsequent they should be thoroughly washed with the nail-brush in one solution or the other. My preference is rather for the chlorinated water, as it is a more thorough disinfectant, and in such proportion as is necessary for the purpose, does not burn the skin nor obtund the tactile sense, as does a carbolized solution. Any instruments which can possibly be required in the labour, forceps, vectis, or catheter, should be treated in the same way with brush, soap, and disinfectant solution always both before and after use. Neither hands nor instruments should ever be wiped upon a towel previously used or soiled; it is better to let both go unwiped, where not a matter of importance, than to risk wiping them upon a doubtful towel.

During the labour systematic cleanliness with the patient should be rigidly observed. If practicable at the onset of parturition, she should take a general bath at about 95 to 100° F., which is useful not only for detergent purposes but also as a promoter of the action of the skin, and as relaxing the muscular fibre, and the tissues generally. After a rectal enema a vaginal enema either of the carbolized or chlorinated solutions above suggested may be given, if the membranes are not ruptured; if they are, or if there be any doubt about it, we should not risk the throwing in of these solutions into the uterine cavity in contact with the fœtus. But the external genitalia should be frequently bathed with one of these solutions, and a soft cloth moistened with the same passed up inside the vaginal cavity from time to time, as far as the finger of the physician or nurse can carry it. The use of the *spray* during the whole process of labour, seems to me to be not only unnecessary, but very annoying to the patient, if done thoroughly enough to be of any service. It involves the necessity of keeping it under the constant observation of an assistant and the genitalia constantly exposed to view; the bed clothing and the patient's person kept all the time wet with it. If a carbolized spray be used the patient's tissues would be irritated and benumbed, and to keep a patient in the agonies of labour in a fixed position in order for this, which is an annoyance to her at any rate, would be a tax upon her forbearance which would be unreasonable. Then again, if it be only during the manipulation of the accoucheur, a carbolized spray would be just as annoying to him as it would be to the patient; saturating the clothing and benumbing the hand and arm. Instead I find perfect satisfaction in keeping at the side of the bed, during the whole time of my manipulations, a dilute Labarraque solution, double the strength of that mentioned; I put into a half-pint toilet cup an ounce of the solution, and fill the cup nearly full of water; in this I keep a small

soft cloth of old muslin or linen; whenever I make the touch I dip the finger into the cup, and from time to time bathe the genitalia with the cloth wrung out in the liquid removing all mucus and blood accumulated, and as the head is descending through the vaginal canal I frequently pass the cloth freshly wrung out in the cup up into the cavity as far as to reach the head. As the head is passing the vulva, distending the perineum, I often keep the cloth in continuous contact with the tissues. Thus there is no possibility of infection taking place either autogenetically or heterogenetically. If any decomposing mass were in the pelvic cavity, a scirrhus or epithelioma, the cleansing would have to be even more vigilant and repeated.

After the delivery of the placenta, I wash out the uterus at once with a syringe with hot water at 115° to 120°, either chlorinated, or acidulated with vinegar, about twenty-five per cent. I formerly used carbolic solution for this, but in two cases in the last year, I saw symptoms which confirmed Fritsch's statements as to the absorption of carbolic solution by the uterus, in the appearance of carbolic poisoning immediately.

For four days after the labour I have the nurse wash out the vagina with carbolized or chlorinated water about 110° F. every four to six hours, If any offensive lochia appear with the least symptom of septic poisoning, I wash out the uterus with the strong ten to fifteen per cent. Labarraque with a double canulated uterine tube, using a siphon generally in preference to a forcing syringe, to avoid the passage of the fluid into the peritoneal cavity.

ADDRESS ON OUR MEDICAL LITERATURE.

Delivered at the International Medical Congress.

By JOHN S. BILLINGS, M.D.,
Surgeon, U. S. Army.

When I was surprised by the honour of an invitation to address this Congress, my first thought was that it must be declined; for the simple but sufficient reason that I had nothing to say that would be worth occupying the time of such an assemblage as it was evident this would be. But while thinking over the matter, and looking absent-mindedly at a shelf of catalogues and a pile of new books and journals awaiting examination, it occurred to me that perhaps some facts connected with our medical literature, past and present, from the point of view of the reader, librarian, and bibliographer, rather than from that of the writer or practitioner, might be of sufficient interest to you to warrant an attempt to present them; and, the wish being probably father to the thought, I decided to make the trial.

When I say "Our Medical Literature," it is not with reference to that of any particular country or nation, but to that which is the common property of the educated physicians of the world as represented here to-day—the literature which forms the intra- and inter-national bond of the medical profession of all civilized countries; and by virtue of which we, who have come hither from the far West and the farther East, do not now meet for the first time as strangers, but as friends, having common interests, and though of many nations, a common language, and whose thoughts are perhaps better known to each other than to some of our nearest members.

It is usual to estimate that about one-thirtieth part of the whole mass of the world's literature belongs to medicine and its allied sciences. This corresponds very well to the results obtained from an examination of bibliographies and catalogues of the principal medical libraries. It appears from this that our medical literature now forms a little over 120,000 volumes properly so called, and about twice that number of pamphlets, and that this accumulation is now increasing at the rate of about 1500 volumes and 2500 pamphlets yearly.

Let us consider the character of this annual growth somewhat in detail, first giving some figures as to the number of those who are producing it.

There are at the present time scattered over the earth about 180,000 medical men, who, by a liberal construction of the phrase, may be said to be educated—that is, who have some kind of a diploma, and for whose edification this current medical literature is produced. Of this number about 11,600 are producers of, or contributors to, this literature, being divided as follows: United States, 2800; France and her Colonies, 2600; the German Empire and Austro-Hungary, 2300; Great Britain and her Colonies, 2000; Italy, 600; Spain, 300; all others, 1000. These figures should be considered in connection with the number of physicians in each country; but this I can only give approximately, as follows: United States, 65,000; Great Britain and her Colonies, 35,000; Germany and Austro-Hungary, 32,000; France and her Colonies, 26,000; Italy, 10,000; Spain, 5000; all others, 17,000.

It will be seen from these figures that the number of physicians who are writers is proportionately greatest in France and least in the United States. As regards France, this is largely due to the requirement of a printed thesis for graduation, which of itself adds between six and seven hundred annually to the number of writers.

Excluding popular medicine, pathies, pharmacy, and dentistry, all of which were included in the figures for the annual product just given, we find that the contributions to medicine, properly so called, form a little over 1000 volumes and 1600 pamphlets yearly.

For 1879 Rupprecht's Bibliotheca gives as the total number of new medical books, excluding pamphlets, periodicals, and transactions, 419; divided as follows—viz.; France, 187; Germany, 110; England, 43; Italy, 32; United States, 21; all others, 26. These figures are, however, too small, and especially so as regards Great Britain and the United States. The Index Medicus for the same year shows by analysis that the total number of medical books and pamphlets, excluding periodicals and transactions, was 1643; divided as follows: France, 541; Germany, 364; United States, 310; Great Britain, 182; all others, 246. This does not include the inaugural theses, of which 693 were published in France alone.

The special characteristics of the literature of the present day are largely due to journals and transactions, and this is particularly true in medicine. Our periodicals contain the most recent observations, the most original matter, and are the truest representations of the living thought of the day, and of the tastes and wants of the great mass of the medical profession, a large part of whom, in fact, read very little else. They form about one-half of the current medical literature, and in the year 1879 amounted to 655 volumes, of which the United States produced 156, Germany, 129, France, 122, Great Britain, 54, Italy, 65, and Spain, 24. This is exclusive of journals of pharmacy, dentistry, etc., and of journals devoted to medical sects and isms. In a table I have drawn out it appears that the total number of volumes of medical journals and transactions of all kinds was, for the year 1879, 850, and for the year 1880, 864. The figures for 1880 are too small, but the real increase is slight. During the year 1879, the

total number of original articles in medical journals and transactions which were though worth noting for the Index Medicus was a little over 20,000. Of these there appeared in American periodicals 4781, in French 4608, in German 4027, in English 3592, in Italian 1210, in Spanish 703, in all others 1248. The figures for 1880 are about the same. It will be seen that at present more of this class of literature appears in the English language than in any other, and that the number of journal contributions is greatest in the United States. The actual bulk of periodical literature is, however, greatest in Germany, owing to the greater average length of the articles. With regard to the mode of publication, I will only say that in all countries except Spain the greater number of medical periodicals are monthly, while in Spain they are semi-monthly. It is this periodical literature which, more than anything else, makes medicine cosmopolitan, and although as regards new discoveries or methods of treatment it is still somewhat farther from London or Berlin or Paris to New York than it is from New York to either of these places, the discrepancy is gradually becoming less.

Many of the medical journals are very short lived, but the total number is increasing. In 1879, 23 such journals ceased, but 60 new ones appeared, and in 1880 there were 24 deaths and 78 births in this department of literature. Over one-third of this fluctuation occurs in the United States alone, France being next in the scale, Spain third, and Italy fourth, while Great Britain is the most stable of all.

This merely quantitative classification gives of course no idea as to the character, and very little as to the value of the product. Let us now consider it by subjects. During 1879 there were published 167 books and pamphlets and 1543 articles relating to anatomy, physiology, and pathology—that is, to the biological or scientific side of medicine. Dividing this again by nations, we find that Germany produced a majority of the whole, France being second. The proportionate production by nations of this class of literature is perhaps better shown by an analysis of the bibliography of physiological literature for the year 1879, as published by the *Journal of Physiology*. This shows 59 treatises and 500 articles in German, 17 treatises and 227 articles in French, 5 treatises and 77 articles from Great Britain, 8 treatises and 41 articles from Italy, and 2 treatises and 24 articles from the United States. The number of authors for this product was—German, 393; French, 119; English, 59; Italian, 39; United States, 19; all others, 41. For the year 1880 the same journal reports 62 treatises and 452 articles from Germany, 23 treatises and 216 articles from France, 12 treatises and 76 articles from Great Britain, 4 treatises and 51 articles from Italy, 6 treatises and 25 articles from the United States, and 10 treatises and 31 articles from all other countries.[1]

When we turn to the literature of the art, or practical side of the profession, the figures are decidedly different. We find over 1200 treatises and 18,000 journal articles which come under this head, and the order of precedence of countries as to quantity is France, United States, Germany, Great Britain, Italy, and Spain. The tables I have constructed give still further subdivisions, showing by nations the number of works and journal articles upon the practice of medicine, surgery, obstetrics, hygiene, etc., for the years 1879 and 1880, and some of the figures will be found interesting. A marked increase has occurred in the literature of hygiene during the last two years, and this especially in England, France,

[1] The difference between these figures and those of the Index Medicus is due, on the one hand, to the fact that the Journal of Physiology includes articles which are placed under other headings in the Index Medicus, and, on the other hand, to the fact that the Journal has a different standard of excellence from that of the Index, rejecting many articles which the latter must accept as original.

Germany, and the United States. The literature of diseases of the nervous system, of ophthalmology, otology, dermatology, and gynæcology is also increasing more rapidly than that of the more general branches.

It would, of course, be extremely unscientific to use these figures as if they represented positively ascertained and compared facts, the accuracy of which, as well as of the classification, could be verified. They represent merely the opinions of an individual—first, as to whether each treatise or pamphlet included in these statistics was worth noting, and second, as to how it should be classed. Had everything been indexed, the figures, for journal articles at least, might have been nearly doubled; while if the selection had been made by a more severe critic they might have been reduced one-half.

If I had to do the work again I should not obtain the same results. The prevailing error is that as regards journal articles the figures are too large, for some of those included are of so little value or interest that they are, I fear, never read by more than two persons.

Be that as it may, I think we can take them as indicating certain differences in the direction of work of the medical authors of the great civilized nations of the earth; but they must be considered as approximations only; and the statistical axiom must be remembered that the results obtained from a large number of facts are applicable to an aggregate of similar facts, but not to single cases. There will be a certain number of medical books and papers printed next year just as there will be a certain number of children born—and as we can within certain limits predict the number of these births and the proportion of the sexes, or even of monsters—so we can within certain limits predict the amount and character of the literature that is yet to come, the ideas that are yet unborn. The differences are due to race, political organization, and density of population. As Dr. Chadwick has pointed out in speaking of the statistics of obstetric literature, one of the chief causes of the multiplication of medical societies is geographical. "In England it is possible for those who are specially interested in gynæcology and obstetrics to attend the meetings of the Obstetrical Society of London, whereas in America the distances are so great that this is impossible." Speaking broadly we may say that at present Germany leads in scientific medicine both in quantity and quality of product, and that the rising generation of physicians are learning German physiology. But the seed has gone abroad, and scientific work is receiving more and more appreciation everywhere.

Seven years ago Professor Huxley declared that if a student in his own branch showed power and originality he dared not advise him to adopt a scientific career, for he could not give him the assurance that any amount of proficiency in the biological sciences would be convertible into the most modest bread and cheese. To-day I think he might be bolder, for such a fear would hardly be justifiable—at all events in America, where such a man as is referred to could almost certainly find a place, bearing in mind the professor's remark that it is no impediment to an original investigator to have to devote a moderate portion of his time to giving instruction either in the laboratory or in the lecture room.

Within the last ten years the literature of France, Germany, Great Britain, and the United States has contained much with regard to medical education and the means for its improvement. In all these countries there is more or less dissatisfaction with the existing condition of things, although there is no general agreement as to the remedy. Solomon's question, "Wherefore is there a price in the hands of a fool to get wisdom, seeing he hath no heart to it?" is now easily answered, for even a fool knows that he must have the semblance of wisdom, and a diploma to imply it, if he is to succeed in the practice of medicine, but to insure the value of a diploma as a proof of education is the difficulty.

This evidence of discontent and tendency to change is a good sign. In these matters stillness means sleep or death—and the fact that a stream is continually changing its bed shows that its course lies through fertile alluvium and not through sterile lava or granite.

I have said that as regards scientific medicine we are at present going to school to Germany. This, however, is not the case with regard to therapeutics either external or internal—in regard to which I presume that the physicians of each nation are satisfied as to their own pre-eminence. At all events it is true that for the treatment of the common diseases a physician can obtain his most valuable instruction in his own country, among those whom he is to treat. Just as each individual is in some respects peculiar and unique, so that even the arrangement of the minute ridges and furrows at the end of his forefinger differs from that of all other forefingers, and is sufficient to identify him; and as the members of certain families require special care to guard against hemorrhage, or insanity, or phthisis; so it is with nations and races. The experienced military surgeon knows this well, and in the United States, which is now the great mixing ground, illustrations of race peculiarities are familiar to every practitioner.

Neither the tendency nor the true value of this current medical literature can be properly estimated by attending to it alone. It is a part of the thought of the age—of that wonderful kaleidoscopic pattern which is unrolling before us, and must be judged in connection with it. From several sources of high authority there have come of late years warnings and laments that science is becoming too utilitarian. For example, Prof. Du Bois-Reymond, in his address upon civilization and science, says that that side of science which is connected with the useful arts is steadily becoming more prominent, each generation being more and more bent on material interests. "Amid the unrest which possesses the civilized world, men's minds live as it were from hand to mouth. . . . And if industry receives its impulse from science, it also has a tendency to destroy science. In short, idealism is succumbing in the struggle with realism, and the kingdom of material interests is coming." Having laid down this rather pessimistic platform, he goes on to state that this is especially the case in America, which is the principal home of utilitarianism, and that it has become the custom to characterize as "Americanization" the dreaded permeation of European civilization by realism. If this characterization is correct, it would seem that Europe is pretty thoroughly Americanized as regards attention to material interests and appreciation of practical results. But the truth of the picture seems to me doubtful. Science is becoming popular, even fashionable, and some of its would-be votaries rival the devotees of modern æstheticism in their dislike and fear of the sunlight of comprehensibility and common sense. The languid scientific swell who thinks it bad style to be practical, who takes no interest in anything but pure science, and makes it a point to refrain from any investigations which might lead to useful results lest he might be confounded with mere "practical men," or inventors, exists and has his admirers. We have such in medicine, and their number will increase.

The separation of biological study from practical medicine, which has of late years become quite marked in the literature of the subject, has its advantages and disadvantages. Thus far the former have far outweighed the latter, and both the science and the art of medicine have been promoted thereby. But are not the physiologists, or, as I believe they prefer to be called, the biologists, separating themselves too completely from medicine for the best interests of their own science, in that they are neglecting human pathology? In our hospital wards, and among our patients, nature is continually performing experiments which the most dextrous operator cannot copy in the laboratory; she is, as Pro-

fessor Foster says, "a relentless and untrammelled vivisector, and there is no secret of the living frame which she has not, or will not, at some time or place, lay bare in misery and pain."

Now, while it is true that Professor Foster, in his address before the British Medical Association last year (which address is the clearest exposition of the aims of the physiology of the present day that I have seen), insists upon the fact that all distinctions between physiology and pathology are fictitious, and declares that attempts to divide them are like attempts to divide meteorology into a science of good and a science of bad weather, his conclusion that the pathologist should be trained in methods of physiological investigation seems to me to be only a part of the truth. The tacit assumption is that all, or at least the most important, phenomena of human disease may be reproduced in the physiological laboratory. If this were only true what a tremendous stride would have been taken towards making medicine a science. Unfortunately, it is not so. Many of the most interesting of these phenomena, the most interesting because as yet the most unexplainable, can only be observed in the sick man himself. Nor have the physiologists as yet made much use of that field which ought to be specially inviting to them—namely, comparative pathology, although the literature of the present time already indicates that a change has begun in this respect.

While it is true that to the graduate of thirty years ago much of the physiological literature of the present day is an unknown tongue, it is also true that the physiologist of the present, who confines himself to laboratory work, will find himself distanced by the man who keeps his clinical and pathological studies and his experimental work well abreast.

The increase in both the amount and value of the literature of the several specialties in medicine is readily seen by a comparison of recent catalogues and bibliographies with those of twenty or thirty years ago, and this increase still continues at a greater rate than prevails in the more general branches. There are great differences of opinion as to th · relative value of this increase and as to its future effect upon the profession, but there can be no doubt as to the fact. There must be specialties and specialists in medicine, and the results will be both good and evil; but the evils fall largely upon those specialists who have an insufficient general education, who attempt to construct the pyramid of their knowledge with the small end as a foundation. It has been said by Dr. Hodgen that "in medicine a specialist should be a skilled physician, and something more; but that he is often something else—and something less." There is truth in this; truth which the young man would do well to consider with care before he begins to specialize his studies; but, on the other hand, it is also true that the great majority of men must limit their field of work very much and very clearly if they hope to achieve success. The tool must have an edge if it is to cut. It is by the labour of specialists that many of the new channels for thought and research have been opened, and if the flood has sometimes seemed to spread too far, and to lose itself in shallow and sandy places, it has nevertheless tended to fertilize them in the end.

The specialists are not only making the principal advances in science, but they are furnishing both strong incentives and valuable assistance towards the collection and preservation of medical literature and the formation of large public libraries.

Burton declares that a great library cannot be improvised, not even if one had the national debt to do it with—thinks that 20,000 volumes is about the limit of what a miscellaneous collection can bring together, and refers especially to the difficulty in creating large public libraries in America. My experience would show that these statements do not apply to medical books. Of these the folios and quartos of three and four hundred years ago seem to have had great capacity

for resistance to ordinary destructive forces. Perhaps much of this is due to the fact that they are not usually injured by too much handling or perusal. True, they are gradually becoming rarer, but at the same time by means of properly organized libraries they are becoming more accessible to all who wish to really use them, and not merely to collect and hide them away. They drift about like the seaweed, but the survivors are gradually finding secure and permanent resting places in the score of great collections of such literature which the world now possesses. At present the currents of trade are carrying them in relatively large numbers to the United States, where medical collectors and specialists are among the best customers of the antiquarian booksellers of Europe. I could name a dozen American physicians who have given to European agents almost unlimited orders for books relating to their several specialties, and upon their shelves may be found books of the 15th and 16th centuries, which may be properly marked as "rarissime."

Not that the rarest books are by any means the oldest. The collector who seeks to ornament his shelves with the Rose of John of Gaddesden, or the Lily of Bernerd de Gordon, the first folios of Avicenna or Celsus, or almost any of the eight hundred medical incunabula described by Hain, will probably succeed in his quest quite as soon as the one who has set his heart on the first editions of Harvey or Jenner, the American tracts on inoculation for smallpox, or complete sets of many of the journals and transactions of the present century.

Whatever may be the chosen line of the book collector, he is the special helper of the public library, and this whether he intend it or not. In most cases his treasures pass through the auction room, and sooner or later the librarian, who can afford to wait, will secure them from further travel. Thanks to the labours of such collectors, I think it is safe to say—what certainly would not have been true twenty years ago—that if the entire medical literature of the world, with the exception of that which is collected in the United States, were to be now destroyed, nearly all of it that is valuable could be reproduced without difficulty.

What is to be the result of this steadily increasing production of books? What will the libraries and catalogues and bibliographies of a thousand, or even of a hundred years hence be like if we are thus to go on in the ratio of geometric progression, which has governed the press for the last few decades? The mathematical formula which would express this, based on the data of the past century, gives an absurd and impossible conclusion, for it shows that if we go on as we have been going there is coming a time when our libraries will become large cities, and when it will require the services of every one in the world, not engaged in writing, to catalogue and care for the annual product. The truth is, however, that the ratio has changed, and that the rate of increase is becoming smaller. In Western Europe, which is now the great centre of literary production, it does not seem probable that the number of writers or readers will materially increase in the future, and it is in America, Russia, and Southern Asia that the greatest difference will be found between the present amount of annual literary product and that of a century hence.

The analogies between the mental and physical development of an individual, and of a nation or society, have been often set forth and commented on, but there is one point where the analogy fails as regards the products of mental activity—and that is that as yet we have devised no process for getting rid of the exuviæ. Growth and development in the physical world imply the changes of death as well as of life—that with the increase of the living tissues there shall also be the excretion and destruction of dead, outgrown, and useless matters which have had their day and served their purpose. But *litera scripta manent*. There is a vast amount of this effete and worthless material in the literature of medicine,

and it is increasing rapidly. Our literature is, in fact, something like the inheritance of the golden dustman, but with this important difference—viz., that when the children raked a few shells or bits of bone from the dustman's heap, and, after stringing them together and playing with them a little while, threw them back, they did not thereby add to the bulk of the pile; whereas our preparers of compilations and compendiums, big and little, acknowledged or not, are continually increasing the collection, and for the most part with material which has been characterized as "superlatively middling, the quintessential extract of mediocrity." A large medical library is in itself discouraging to many inquirers, and I have become quite familiar with the peculiar expression of mingled surprise, awe, and despair which is apt to steal over the face of one not accustomed to such work when he first finds himself fairly in the presence of the mass of material which he wishes to examine for the purpose of completing his ideal bibliography of—let us say epilepsy, or excisions, or the functions of the liver.

Let such inquirers, as well as those who regret that they have no access to large libraries, and must therefore rely on the common text-books and current periodicals for bibliography, console themselves with the reflection that much the larger part of all of our literature which has any practical value belongs to the present century, and, indeed, will be found in the publications of the last twenty years.

There are a few books written prior to 1800 which every well-educated medical man should—I will not say read but—dip into, such as some of the works of Hippocrates and Galen, of Harvey and Hunter, of Morgagni and Sydenham; but this is to be done to learn their methods and style rather than their facts or theories, and by the great majority of physicians it can be done with much more profit in modern translations than in the originals. The really valuable part of the observations of these old masters has long ago become a part of the common stock, and the results are to be found in every text-book.

If, perchance, among the dusty folios there are stray golden grains yet ungleaned, remember that just in front are whole fields waiting the reaper. There is not, and has not been, any lack of men who have the taste and time to search the records of the past, and the man who has opportunities to make experiments or observations for himself wastes his time, to a certain extent, if he tries to do bibliographical work so long as he can get it done for him. He wishes to know whether this problem has been attacked before, and with what result—whether there are accounts of any other cases like the one he has in hand. In ninety-nine instances out of a hundred if the answers to these questions are not given in the current text-books or monographs it is not worth prolonged search by the original investigator. Yet he should know how to make this search, if only to enable him to direct others, and it is for this reason that a little acquaintance with bibliographical methods of work ought to be obtained by the student.

When a physician has observed (or thinks he has observed) a fact, or has evolved from his inner consciousness a theory which he wishes to examine by the light of medical literature, he is often very much at a loss to know how to begin, even when he has a large library accessible for the purpose.

The information he desires may be in the volume next his hand, but how is he to know that? And even when the usual subject-catalogue is placed before him he finds it very difficult to use it, especially when, as is often the case, he has by no means a well-defined idea as to what it is he wishes to look for. Upon the title-page of the Washington City Directory is printed the following aphorism, "To find a name you must know how to spell it." This has a very extensive application in medical bibliography. To find accounts of cases similar to your own rare case you must know what your own case is.

To return to the subject-catalogue. If it is a classed catalogue—a catalogue raisonnée—it will often seem to be a very blind guide to one who is not familiar with the classification and nomenclature adopted by the compiler. And certainly some of these classifications are very curious—reminding one of Heine's division of ideas into reasonable ideas, unreasonable ideas, and ideas covered with green leather. But if the inquirer has mastered the arrangement of the catalogue, it is two to one that it will not help him. It is a catalogue of the titles of books, but very often the title of a book gives very little information as to its contents, if, indeed, it is not actually misleading. Now, suppose the particular case he has in hand is one of a new-born infant having one leg much larger and longer than the other. He will find no book title relating to this. There may be a book in the library on diseases of the lymphatics which contains just what he wants, but unless he knows that his case is one affecting the lymphatics, he will hardly get the clue. There may also be in the library twenty papers, in as many different volumes of journals and transactions, the titles of which show that they probably relate to similar cases, but the titles of such papers do not appear in the catalogue.

It should also be observed that subject-catalogues may easily be put to improper uses, or thought to give more information than they really do. They are not bibliographies, but mechanical aids in bibliographical work.

You will perhaps pardon me for taking as an illustration the Index-Catalogue of the Library of the Surgeon-General's Office, in Washington, as being one with which I am familiar, and which I can venture to comment on without risk of its being thought that I wish to depreciate its value. Taking any given subject in medicine, it is possible for a fairly educated physician to obtain from this catalogue a large proportion of all the references which have any special value, and by so doing to save a vast amount of time and labour. On the other hand, he will find, when he comes to examine the books and articles referred to, that at least one-half of them are of no value so long as the other half are accessible, seeing that they are dilutions and dilatations, rehashes and summaries of the really original papers. If the seeker is in the library itself this does not cause a great waste of time, as he can rapidly examine and lay aside those that do not serve his purpose. But if he is using this catalogue in another library—say here in London, the case is different. It is highly improbable that he will find in any other collection all the books referred to, and then comes the annoyance of the doubt as to whether he may not be missing some very valuable paper. How is he to know whether or not Smith in his pamphlet on the functions of the pneumogastric has anticipated his own theory of its relations to enlarged tonsils? And in all such cases *omne ignotum est pro magnifico*. In a bibliography of the subject, prepared from the same material as the catalogue, he would either find no mention of Smith's paper, or, better still, a note that his paper is merely an abstract or compilation. The fact that he does not find Smith's book in the London library, nor any allusion to it in the best works on the subject, ought to induce him to ignore it altogether.

In proportion to the energy of the young writer, and his determination to not only note everything that has been written about his subject, but to carry out the golden rule of verifying all his references, he is apt to be led off from his direc research into the many attractive by-paths of quaint and curious speculation which he will find branching off on every side, and this danger must be guarded against, or he will find that he is wasting his time and energy in turning over chaff which has long ago been pretty thoroughly threshed and winnowed.

It is, however, no part of my present purpose to set forth the methods and principles of bibliography, it is sufficient to point out their importance, and to call attention to the point that a knowledge of how and where to find the record of a

fact is often of more practical use than a knowledge of the fact itself, just as we value an encyclopædia for occasional reference, and not for the purpose of reading through from cover to cover.

Instruction in the history and literature of medicine forms no part of the course of medical education in English and American schools, nor should I be disposed to recommend its introduction into the curriculum if it were to be based on French and German models, but it does seem possible to take a step in this direction which would be of great value; not only as a means of general culture, as teaching students how to think, but from a purely practical point of view, in teaching them how to use the implements of their profession to the best advantage—for books are properly compared to tools of which the index is the handle. Such instruction should be given in a library, just as chemistry should be taught in a laboratory. The way to learn history and bibliography is to make them—the best work of the instructor is to show his students how to make them.

In the absence of some instruction of this kind the student is liable to waste much time in bibliographical research. There has been much more done in this direction than many writers seem to suppose, and there are not many subjects in medicine which have not been treated from this point of view. Of course, all is not bibliography which pretends to be such, very many of the exhaustive and exhausting lists of references which are now so common in medical journal articles have been taken largely at secondhand, and thereby originate or perpetuate errors. It is well to avoid false pride in this matter. To overlook a reference is by no means discreditable—but a wrong reference, or an unwitting reference to the same thing twice gives a strong presumption of carelessness and secondhand work. Journal articles, however, and especially reports of cases, undergo strange transmogrifications sometimes, and I have watched this with interest in the case of a French or German paper, translated and condensed in the *London Record*, then appearing in abstract under the name of the translator in a leading journal, then translated again, with a few new circumstances, in a continental periodical, and finally perhaps reversed and appearing as an original contribution in the pages of the *Little Peddlington Medical Universe*.

In this connection it is well to remember that a mere accumulation of observations, no matter how great the number, does not constitute science, especially if these observations have been recorded under the influence of the same theories and in essentially similar conditions.

Science seeks the law which governs or explains the phenomena, and when this is found the records of isolated instances of its action usually become of small importance so far as that law is concerned. We care little now for the records of the chemical experiments of a century ago, and the many detailed accounts of the earlier cases of the use of ether or chloroform are of so little interest at the present time that it is not worth while to refer to them in a bibliography of the subject. And although much has been done towards classifying and indexing our medical records (more, in fact, than most physicians suppose), still, as Helmholtz points out, such knowledge as this hardly deserves the name of science, since it neither enables us to see the complete connection nor to predict the result under new conditions yet untried.

Do I seem to depreciate the value of the thoughts which our masters have left us, and which have furnished the foundations on which we build?—or to undervalue the importance of the great medical libraries in which are stored these thoughts?—or to speak slightly of the utility of the catalogues, and indexes, and bibliographies, without which such libraries are trackless and howling wildernesses? If so, I have said what I did not mean to say. The subject has been considered from the point of view of what used to be called the division of

labour, but which now I suppose should be called evolution and differentiation; and this has been done because "life is short and the art is long," with fair prospect of becoming longer. It is surely unnecessary for me to enter upon any panegyric of books or libraries. As Dr. Holmes says, "It is not necessary to maintain the direct practical utility of all kinds of learning. Our shelves contain many books which only a certain class of medical scholars will be likely to consult. There is a dead medical literature, and there is a live one. The dead is not all ancient; the live is not all modern. There is none, modern or ancient, which, if it has no living value for the student, will not teach him something by its autopsy. But it is with the live literature of his profession that the medical practitioner is first of all concerned."

In medicine, as in social science, we must depend for many facts upon the observation of conditions which occur very rarely, and which cannot be repeated at pleasure. I have already alluded to the importance of Nature's vivisections to the physiologist, and a record of a case written a century ago may be just the link that is needed to correlate the results of his experiments of yesterday with existing theories. The case which at first seems unique and inexplicable both receives and furnishes light when compared with ancient records.

A science of medicine, like other sciences, must depend upon the classification of facts, upon the comparison of cases alike in many respects, but differing somewhat either in their phenomena or in the environment. The great obstacle to the development of a science of medicine is the difficulty in ascertaining what cases are sufficiently similar to be comparable, which difficulty is in its turn largely due to insufficient and erroneous records of the phenomena observed. This defect in the records is largely due, first, to ignorance on the part of observers; second, to the want of proper means for precisely recording the phenomena; and, third, to the confused and faulty condition of our nomenclature and nosological classifications.

Let us consider each of these points briefly. Very, very few are the men who can by and for themselves see and describe the things that are before them. Just as it took thousands of years to produce a man who could see what now any one can see when shown him, that the star Alpha in Capricorn is really two separate stars, so we had to wait long before the man came who could see the difference between measles and scarlatina, and still longer for the one who could distinguish between typhus and typhoid. Said Plato, "He shall be as a god to me who can rightly divide and define." Men who have this faculty—the "Blick" of the Germans—we cannot produce directly by any system of education; they come, we know not when or why, "forming a small band, a mere understanding of whose thoughts and works is a test of our highest powers. A single English dramatist and a single English mathematician have probably equalled in scope and excellence of original work in their several fields all the like labours of their countrymen put together."[1]

But cannot we do something to increase the number of observers by telling them what to observe? It is probable that much may be accomplished in this direction provided that care be taken to limit the field. Manuals of "what to observe at the bedside and in the post-mortem room" are very well in their way, but can never be made to reach the great majority of the profession, nor would they be of much use if they did. If a few, a very few, distinct specific questions are brought to the attention of the general practitioner, he will often be on the alert for their answer. And it should be remembered that chance may present to the most obscure practitioner an opportunity for observation which the greatest master may never meet.

[1] Iles, Mathematics in Evolution. Pop. Sci. Monthly, 1876, ix. p. 207.

The great difficulty is to get such questions prepared. They must relate to matters that are just in the nebulous region between the known and unknown—to points not yet clear, but of which we know enough to make it probable that by observing in a definite direction they can be made clear; and to prepare them requires not only knowledge, but a certain reaching out beyond knowledge. It usually happens that the man who has this faculty strives to answer his questions himself, and no doubt he can usually do it better than another. But much can be done towards defining and marking out what we do not know, and this has been a powerful aid to the progress of physiology in recent years. I have had occasion to refer to this in speaking of Prof. Foster's work on physiology, in each section of which an attempt is made to separate that which may be considered as proved from that which is merely probable; and thus almost every page becomes suggestive of work to be done.

Another example of what I mean will be found in a paper on the collection of data at autopsies by Professor H. P. Bowditch, of Boston (Trans. Mass. Med.-Legal Soc. 1, 1880, p. 189). Taking the results of an investigation into the absolute and relative size of organs at different periods of life, and in connection with different morbid tendencies, recently published by Professor Beneke, of Warburg, Dr. Bowditch urges the securing as large a number as possible of such data, and selects certain of Professor Beneke's results for special inquiry; as, for instance, that "the cancerous diathesis is associated with a large and powerful heart, capacious arteries, but a relatively small pulmonary artery, small lungs, well developed bones and muscles, and tolerably abundant adipose tissue." It can hardly be doubted that those who read the papers of Professors Bowditch and Beneke will be induced to examine things which before would have had for them no interest, and, therefore, to make and record observations in pathological anatomy which otherwise would have been lost.

The second difficulty referred to—viz., the want of means for making accurate records—is one that is yearly growing less. It behooves us to be modest in our predictions as to what may be accomplished in the future towards the solution of our Sphinx's riddle. We see as through a glass darkly, and except through the glass in no wise; but, at least, we have made such progress that what we do see we can, to a great extent, so record that our successors yet unborn can also see, and it is owing to this fact that a part of the medical literature of the last quarter of the nineteenth century will be more valuable than all that has preceded it.

The word-pictures of disease traced by Hippocrates and Sydenham, or even those of Graves and Trousseau, interesting and valuable as they are, are not comparable with the records upon which the skilled clinical teacher of the present day relies. Yet how imperfect in many cases are even the best of these records as compared with what might be given with the resources which we have at our command. The temperature chart has done away with the errors which necessarily follow attempts to compare the memory of sensations perceived last week with the sensations of to-day—and the balance and the burette enable us to estimate with some approach to precision the tissue changes of our patients by the records of change in the excretions which they furnish; but we must still trust to our memory, or to the imperfect descriptions of what others remember, when we attempt to compare the results obtained on successive days by auscultation or percussion, although the phonograph and microphone strongly hint to us the possibility of either accurately reproducing the sounds of yesterday, or of translating them into visible signs, perhaps something like the dot and dash record of the telegraph code, which could then be given to the press, and so compared with each other by readers at the antipodes.

We are beginning to count the blood corpuscles, and to use photomicrography,

but we do not yet apply the latter process to the former so as to enable every reader to count for himself.

The connections of medicine with the physical sciences are yearly becoming closer, and the methods by which these sciences have been brought to their present condition are those by which progress has been, and is to be, made in therapeutics as well as in diagnosis or in physiological research. These methods turn mainly upon increasing the delicacy and accuracy of measurements; of expressing manifestations of force in terms of another force, or of dimension in space or time. The balance and the galvanometer, the microscope and the pendulum, the camera, the sphygmograph and the thermometer are some of the means by which investigators, at the bedside and in the laboratory, are seeking to obtain records which shall be independent of their own sensations or personal equations; which shall be taken and used as expressing not opinions, but facts; and with every addition to or improvement in these means of measurement and record, the field of observation widens, and new and more reliable materials are furnished for the application of logical and mathematical methods.

Upon the third difficulty which has been referred to, viz., our confused and defective terminology, I need not dwell. "Science," said Condillac, "is a language well made," and though this is far from being the whole truth, it is an important part of it. In examining medical reports and statistics, it is necessary to bear constantly in mind that to understand many terms you must know what the individual writer means by them. When, for example, we find in such statistics a certain number of deaths attributed to gastro-enteritis, or croup, or scrofula, we have to take into account the country, the period, and the individual author, in order to get even a fair presumption as to what is meant.

The three difficulties which have been referred to, although the most important, are by no means the only causes of the confusion and imperfection of our records.

Prominent among the minor troubles of the investigator are defective or misleading titles, and in behalf of the readers and bibliographers of the future I would appeal to authors, and more especially to editors, to pay more attention than many of them do to the matter of titles and indexes. The men to whom your papers are most important, and who will make the best use of them provided they know of their existence, are for the most part hard workers, busy men who have a right to demand that their literary table shall be provided with properly prepared materials and not with shapeless lumps.

The editors of Transactions of Societies, whether these are sent to journals or published in separate form, often commit numerous sins of omission in the matter of titles. The rule should be that every article which is worth printing is worth a distinct title, which should be as concise as a telegram, and be printed in a special type. If the author does not furnish such a title, it is the editor's business to make it; and he should not be satisfied with such headings as "Clinical Cases," "Difficult Labour," "A Remarkable Tumour," "Case of Wound, with Remarks." The four rules for the preparation of an article for a journal will then be: 1. Have something to say. 2. Say it. 3. Stop as soon as you have said it. 4. Give the paper a proper title.

Some societies and editors do not seem to appreciate fully their responsibility for the articles which they accept for publication; a responsibility which cannot be altogether avoided by any formal declaration disclaiming it. This is due to the fact that while the merits of a paper can usually be determined by examination, this is by no means always the case. In every country there are writers and speakers whose statements are received with very great distrust by those best acquainted with them. Supposing these statements to be true, the papers

would be of much interest and importance; but the editor should remember that a certain number of readers, and especially those in foreign countries, have no clue to the character of the author beyond the fact that they find his works in good company. In medical literature, as in other departments, we find books and papers from men who are either constitutionally incapable of telling the simple, literal truth as to their observations and experiments, although they may not write with fixed intentions to deceive, or from men who seek to advertise themselves by deliberate falsehoods as to the results of their practice. Such men are usually appreciated at their true value in their immediate neighbourhood, and find it necessary to send their communications to distant journals and societies in order to secure publication.

I presume that you are all familiar with the peculiar feeling of distrust which is roused by too complete an explanation. The report of a case in which every symptom observed, and the effect of every remedy given is fully accounted for, and in which no residual unexplained phenomena appear, is usually suspicious, for it implies either superficial observation or suppression, or distortion of some of the facts. A diagrammatic representation is usually much plainer than a good photograph, but also of much less value as a basis for further work.

No fact is more familiar to this audience than the vast extent of the field of the science of to-day—so vast that few may hope to master more than a small part of it, and yet so closely connected that even the small part cannot be fully grasped without some acquaintance with a much wider field.

But little over a hundred years ago, Haller, in Göttingen, was professor of anatomy, botany, physiology, surgery, and obstetrics, and lecturer on medical jurisprudence At the same time he was writing one review a week, and summing up existing medical science in his "Bibliotheca." To-day any one of these branches requires all the time of the most energetic and learned of our contemporaries; but, on the other hand, the well-educated medical graduate of to-day could give Haller valuable instruction in each of the branches of which he was professor. It is also true, as I have pointed out, that our actual progress is by no means in proportion to the work done, nor as great as these merely quantitative statements would seem to make it.

Science has been termed "the topography of ignorance." From a few elevated points we triangulate vast spaces, inclosing infinite unknown details. We cast the lead, and draw up a little sand from abysses we shall never reach with our dredges.

If it is true that we understand ourselves but imperfectly in health, it is more signally manifest in disease, where natural actions imperfectly understood, disturbed in an obscure way by half-seen causes, are creeping and winding along in the dark towards their destined issue, sometimes using our remedies as safe stepping-stones, occasionally, it may be, stumbling over them as obstacles.[1]

In days of old, when the profession of medicine, or of a single medical specialty, was an inheritance in certain families, a large part of their knowledge and the efficiency of their remedies was thought to depend upon these being kept a profound mystery. Among the precepts of magic there was no more significant one than that which declared that the communication of the formula destroyed its power, and that hence attempts to reveal the secret must always fail.

We have changed all that. Every physician hastens to publish his discoveries and special knowledge, and a good many do the same by that which is not special, or which is not knowledge. For the individual, in a degree—for the nation or the race in a much greater degree—the literature produced is the most endur-

[1] Border Lines of Knowledge, etc., by O. W. Holmes, Boston, 1862, pp. 7, 8.

ing memorial. The whole result of civilization has been cynically defined as being roughly, "Three hundred million Chinese, two hundred million natives of India, two hundred million Europeans and North Americans, and a miscellaneous hundred million or two of Central Asians, Malays, South Sea Islanders, etc., and over and above all the rest the Library of the British Museum. This is the net result of an indefinitely long struggle between the forces of men and the weights of various kinds in the attempt to move which these forces display themselves."[1]

And thus in our great medical libraries each of the folios or quaint little black-letter pamphlets which mark the first two centuries of printing, or of the cheap and dirty volumes of more modern days, with their scrofulous paper and abominable typography, represents to a great extent the life of one of our profession and the fruit of his labours, and it is by the fruit that we know him.

After stating that modern physicists have concluded that the sun is going out, that the earth is falling into the sun, and therefore that it and all things in it will be either fried or frozen, Professor Clifford concludes that "our interest lies so much with the past as may serve to guide our actions in the present, and with so much of the future as we may hope will be affected by our actions now. Beyond that we do not know and ought not to care. Does this seem to say, Let us eat and drink, for to-morrow we die? Not so, but rather, Let us take hands and help, for this day we are alive together." To this I join a verse from the Talmud, which will remind you of the first aphorism of Hippocrates, and is none the worse for that: "The day is short, and work is great—the reward is also great, and the master presses. It is not incumbent on thee to complete the work, but thou must not therefore cease from it."—*Lancet*, Aug. 13, 1881.

TRANSLATION OF AN ADDRESS ON THE GERM THEORY.

Delivered at the International Medical Congress, London, August, 1881.

BY PROFESSOR PASTEUR.

GENTLEMEN: I had no intention of addressing this admirable Congress, which brings together the most eminent medical men in the world, and the great success of which does so much credit to its principal organizer, Mr. Mac Cormac. The good-will of your esteemed President has decided otherwise. How could one, in fact, resist the sympathetic words of that eminent man whose goodness of heart is associated in no small degree with great oratorical ability? Two motives have brought me to London. The first was to gain instruction, to profit by your learned discussions; and the second was to ascertain the place now occupied in medicine and surgery by the germ theory. Certainly I shall return to Paris well satisfied. During the past week I have learned much. I carry away with me the conviction that the English people are a great people, and as for the influence of the new doctrine, I have been not only struck by the progress it has made, but by its triumph. I should be guilty of ingratitude and of false modesty if I did not accept the welcome I have received among you and in English society as a mark of homage paid to my labours during the past five-and-twenty years upon the nature of ferments—their life and their nutrition, their preparation in a pure state by the introduction of organisms (*ensemencement*) under natural and artificial conditions — labours which have established the principles and the methods of microbie (microbism), if the expression is allowable. Your cordial

[1] Liberty, Equality, and Fraternity, by James Fitz James Stephen, N. Y. 1873, p. 178.

welcome has revived within me the lively feeling of satisfaction I experienced when your great surgeon Lister declared that my publication in 1857 on milk fermentation had inspired him with his first ideas on his valuable surgical method. You have reawakened the pleasure I felt when our eminent physician Dr. Davaine declared that his labours upon charbon (splenic fever or malignant pustule) had been suggested by my studies on butyric fermentation and the vibrion which is characteristic of it. Gentlemen, I am happy to be able to thank you by bringing to your notice a new advance in the study of microbie as applied to the prevention of transmissible diseases—diseases which for the most part are fraught with terrible consequences, both for man and domestic animals. The subject of my communication is vaccination in relation to chicken cholera and splenic fever, and a statement of the method by which we have arrived at these results—a method the fruitfulness of which inspires me with boundless anticipations. Before discussing the question of splenic fever vaccine, which is the most important, permit me to recall the results of my investigations of chicken cholera. It is through this inquiry that new and highly important principles have been introduced into science concerning the virus or contagious quality of transmissible diseases. More than once in what I am about to say I shall employ the expression virus-culture, as formerly, in my investigations on fermentation, I used the expressions, the culture of milk ferment, the culture of the butyric vibrion, etc.

Let us take, then, a fowl which is about to die of chicken cholera, and let us dip the end of a delicate glass rod in the blood of the fowl with the usual precautions, upon which I need not here dwell. Let us then touch with this charged point some *bouillon de poule*, very clear, but first of all rendered sterile under a temperature of about 115° Centigrade, and under conditions in which neither the outer air nor the vases employed can introduce exterior germs—those germs which are in the air, or on the surface of all objects. In a short time, if the little culture vase is placed in a temperature of 25° to 35°, you will see the liquid become turbid, and full of tiny microbes, shaped like the figure 8, but often so small that under a high magnifying power they appear like points. Take from this vase a drop as small as you please, no more than can be carried on the point of a glass rod as sharp as a needle, and touch with this point a fresh quantity of sterilized *bouillon de poule* placed in a second vase, and the same phenomenon is produced. You deal in the same way with a third culture vase, with a fourth, and so on to a hundred, or even a thousand, and invariably within a few hours the culture liquid becomes turbid and filled with the same minute organisms. At the end of two or three days' exposure to a temperature of about 30° C. the thickness of the liquid disappears, and a sediment is formed at the bottom of the vase. This signifies that the development of the minute organism has ceased—in other words, all the little points which caused the turbid appearance of the liquid have fallen to the bottom of the vase, and things will remain in this condition for a longer or shorter time, for months even, without either the liquid or the deposit undergoing any visible modification, inasmuch as we have taken care to exclude the germs of the atmosphere. A little stopper of cotton sifts the air which enters or issues from the vase through changes of temperature. Let us take one of our series of culture preparations—the hundredth or the thousandth, for instance—and compare it in respect to its virulence with the blood of a fowl which has died of cholera; in other words, let us inoculate under the skin ten fowls, for instance, each separately with a tiny drop of infectious blood, and ten others with a similar quantity of the liquid in which the deposit has first been shaken up. Strange to say, the latter ten fowls will die as quickly and with the same symptoms as the former ten; the blood of all will be found to contain after death the same minute infectious organisms. This equality, so to speak, in the virulence both of the

culture preparation and of the blood is due to an apparently futile circumstance. I have made a hundred culture preparations—at least, I have understood that this was done—without leaving any considerable interval between the impregnations. Well, here we have the cause of the equality in the virulence. Let us now repeat exactly our successive cultures with this single difference, that we pass from one culture to that which follows it—from the hundredth to, say, the hundred and first, at intervals of a fortnight, a month, two months, three months, or ten months. If, now, we compare the virulence of the successive cultures, a great change will be observed. It will be readily seen from an inoculation of a series of ten fowls that the virulence of one culture differs from that of the blood and from that of a preceding culture when a sufficiently long interval elapses between the impregnation of one culture with the microbe of the preceding. More than that, we may recognize by this mode of observation that it is possible to prepare cultures of varying degrees of virulence. One preparation will kill eight fowls out of ten, another five out of ten, another one out of ten, another none at all, although the microbe may still be cultivated. In fact, what is no less strange, if you take each of these cultures of attenuated virulence as a point of departure in the preparation of successive cultures and without appreciable interval in the impregnation, the whole series of these cultures will reproduce the attenuated virulence of that which has served as the starting point. Similarly, where the virulence is null it produces no effect. How, then, it may be asked, are the effects of these attenuating virulences revealed in the fowls? They are revealed by a local disorder, by a morbid modification more or less profound in a muscle, if it is a muscle which has been inoculated with the virus. The muscle is filled with microbes which are easily recognized because the attenuated microbes have almost the bulk, the form, and the appearance of the most virulent microbes. But why is not the local disorder followed by death? For the moment let us answer by a statement of facts. They are these: the local disorder ceases of itself more or less speedily, the microbe is absorbed and digested, if one may say so, and little by little the muscle regains its normal condition. Then the disease has disappeared. When we inoculate with the microbe the virulence of which is null there is not even local disorder, the *naturæ medicatrix* carries it off at once, and here, indeed, we see the influence of the resistance of life, since this microbe, the virulence of which is null, multiplies itself. A little further, and we touch the principle of vaccination. When the fowls have been rendered sufficiently ill by the attenuated virus which the vital resistance has arrested in its development, they will, when inoculated with virulent virus, suffer no evil effects, or only effects of a passing character. In fact, they no longer die from the mortal virus, and for a time sufficiently long, which in some cases may exceed a year, chicken cholera cannot touch them, especially under the ordinary conditions of contagion which exist in fowl-houses. At this critical point of our manipulation—that is to say, in this interval of time which we have placed between two cultures, and which causes the attenuation—what occurs? I shall show you that in this interval the agent which intervenes is the oxygen of the air. Nothing more easily admits of proof. Let us produce a culture in a tube containing very little air, and close this tube with an enameller's lamp. The microbe in developing itself will speedily take all the oxygen of the tube and of the liquid, after which it will be quite free from contact with oxygen. In this case it does not appear that the microbe becomes appreciably attenuated, even after a great lapse of time. The oxygen of the air, then, would seem to be a possible modifying agent of the virulence of the microbe of chicken cholera—that is to say, it may modify more or less the facility of its development in the body of animals. May we not be here in presence of a general law applicable

to all kinds of virus? What benefits may not be the result? We may hope to discover in this way the vaccine of all virulent diseases; and what is more natural than to begin our investigation of the vaccine of what we in French call charbon, what you in England call splenic fever, and what in Russia is known as the Siberian pest, and in Germany as the Milzbrand. In this new investigation I have had the assistance of two devoted young *savants*—MM. Chamberland and Roux. At the outset we were met by a difficulty. Among the inferior organisms, all do not resolve themselves into those corpuscle germs which I was the first to point out as one of the forms of their possible development. Many infectious microbes do not resolve themselves in their cultures into corpuscle germs. Such is equally the case with beer yeast, which we do not see develop itself usually in breweries, for instance, except by a sort of scissiparity. One cell makes two or more, which form themselves in wreaths; the cells become detached, and the process recommences. In these cells real germs are not usually seen. The microbe of chicken cholera and many others behave in this way, so much so that the cultures of this microbe, although they may last for months without losing their power of fresh cultivation, perish finally like beer yeast which has exhausted all its aliments. The anthracoid microbe in artificial cultures behaves very differently. In the blood of animals, as in cultures, it is found in translucid filaments more or less segmented. This blood or these cultures freely exposed to air, instead of continuing according to the first mode of generation, show at the end of forty-eight hours corpuscle germs distributed in series more or less regular along the filaments. All around those corpuscles matter is absorbed, as I have represented it formerly in one of the plates of my work on the disease of silkworms. Little by little all connection between them disappears, and presently they are reduced to nothing more than germ dust. If you make these corpuscles germinate, the new culture reproduces the virulence peculiar to the thready form which has produced these corpuscles, and this result is seen even after a long exposure of these germs to contact with air. Recently we discovered them in pits in which animals dead of splenic fever had been buried for twelve years, and their culture was as virulent as that from the blood of an animal recently dead. Here I regret extremely to be obliged to shorten my remarks. I should have had much pleasure in demonstrating that the anthracoid germs in the earth of pits in which animals have been buried are brought to the surface by earthworms, and that in this fact we may find the whole etiology of disease, inasmuch as the animals swallow these germs with their food. A great difficulty presents itself when we attempt to apply our method of attenuation by the oxygen of the air to the anthracoid microbes. The virulence establishing itself very quickly, often after four-and-twenty hours in an anthracoid germ which escapes the action of the air, it was impossible to think of discovering the vaccine of splenic fever in the conditions which had yielded that of chicken cholera. But was there, after all, reason to be discouraged? Certainly not; in fact, if you observe closely, you will find that there is no real difference between the mode of the generation of the anthracoid germ by scission and that of chicken cholera. We had therefore reason to hope that we might overcome the difficulty which stopped us by endeavouring to prevent the anthracoid microbe from producing corpuscle germs and to keep it in this condition in contact with oxygen for days, and weeks, and months. The experiment fortunately succeeded. In the ineffective (*neutre*) *bouillon de poule* the anthracoid microbe is no longer cultivable at 45° C. Its culture, however, is easy at 42° or 43°, but in these conditions the microbe yields no spores. Consequently it is possible to maintain in contact with the pure air at 42° or 43° a *mycélienne* culture of bacteria entirely free of germs. Then appear the very remarkable results which follow. In a month or six weeks the culture dies—that

is to say, if one impregnates with it fresh *bouillon*, the latter is completely sterile. Up till that time life exists in the vase exposed to air and heat. If we examine the virulence of the culture at the end of two days, four days, six days, eight days, etc., it will be found that long before the death of the culture the microbe has lost all virulence, although still cultivable. Before this period it is found that the culture presents a series of attenuated virulences. Everything is similar to what happens in respect to the microbe in chicken cholera. Besides, each of these conditions of attenuated virulence may be reproduced by culture.; in fact, since the charbon does not operate a second time (*ne récidive pas*), each of our attenuated anthracoid microbes constitutes for the superior microbe a vaccine—that is to say, a virus capable of producing a milder disease. Here, then, we have a method of preparing the vaccine of splenic fever. You will see presently the practical importance of this result, but what interests us more particularly is to observe that we have here a proof that we are in possession of a general method of preparing virus vaccine based upon the action of the oxygen and the air—that is to say, of a cosmic force existing everywhere on the surface of the globe. I regret to be unable from want of time to show you that all these attenuated forms of virus may very easily, by a physiological artifice, be made to recover their original maximum virulence. The method I have just explained of obtaining the vaccine of splenic fever was no sooner made known than it was very extensively employed to prevent the splenic affection. In France we lose every year by splenic fever animals of the value of 20,000,000f. I was asked to give a public demonstration of the results already mentioned. This experiment I may relate in a few words. Fifty sheep were placed at my disposition, of which twenty-five were vaccinated. A fortnight afterwards the fifty sheep were inoculated with the most virulent anthracoid microbe. The twenty-five vaccinated sheep resisted the infection; the twenty-five unvaccinated died of splenic fever within fifty hours. Since that time my energies have been taxed to meet the demands of farmers for supplies of this vaccine. In the space of fifteen days we have vaccinated in the departments surrounding Paris more than 20,000 sheep and a large number of cattle and horses. If I were not pressed for time I should bring to your notice two other kinds of virus attenuated by similar means. These experiments will be communicated by and by to the public. I cannot conclude, gentlemen, without expressing the great pleasure I feel at the thought that it is as a member of an international medical congress assembled in England that I make known the most recent results of vaccination upon a disease more terrible, perhaps, for domestic animals than smallpox is for man. I have given to vaccination an extension which science, I hope, will accept as homage paid to the merit and to the immense services tendered by one of the greatest men of England, Jenner. What a pleasure for me to do honour to this immortal name in this noble and hospitable city of London!—*Lancet*, Aug. 13, 1881.

ADDRESS ON THE CHANGES WHICH SURGERY HAS UNDERGONE DURING THE LAST TEN YEARS.

Delivered at the Meeting of the International Medical Congress, London, 1881.

BY PROFESSOR VOLKMANN.

GENTLEMEN: It is with hesitation and only in accordance with the wish of my London friends that I have undertaken to speak before such a distinguished assembly, and to make an attempt to sketch a hasty picture of the changes which

surgery has experienced in the last fifteen or even ten years. And I trust that in this attempt I may rely on your special indulgence; for great and unparalleled in the history of medical science have been those changes. Problems thousands of years old have been solved, or are at any rate approaching a sure solution; the desires of our fathers have been fulfilled beyond their hope or expectation. But all our practice and theories have been also fundamentally altered. The position of our science, the position that we ourselves occupy towards invalids, have become entirely different. And this revolution, in the midst of which we still stand, although the first wave has exhausted itself, has been called forth by the one incontestable fact, that all those countless and disastrous disturbances by which the wounds and hence also the life of those operated on or injured are threatened are only the consequences of particular processes of decomposition of the animal fluids, brought about by the intrusion of lower organisms.

For with the recognition of the manner of their origin, and with the knowledge of their nature, we have also gained the power of preventing these disturbances. Conscious of our aim, we are able so to act as to prevent the evil influences of these micro-organisms. The fate of countless invalids is from henceforth placed in our hands. In the place of blind chance, in the place of fortune or misfortune, which formerly played so great a part in the work of the practical surgeon, there now appear, in quite a different degree, knowledge and ignorance, capability and inability, care and carelessness. But a short time ago the surgeon, when he had, according to the rules of his art, made a wound, was like the husbandman who, when he has sown his field, patiently awaits the harvest, and accepts it as it may turn out, powerlessly exposed to the elements which may bring him rain and sunshine, storm and hail. Now he is the manufacturer from whom we expect good wares. By rescuing from the domain of chance the results of our labours, as far as they depend on operations and the treatment of wounds—and this will always remain the chief and especial work of surgery—the antiseptic method has elevated surgery to the rank of the latest experimental science.

Never has a discovery been made in surgery which has even approached this in its benefits to humanity in general. Many thousands of human beings have in the short space of time that has elapsed since then preserved life and limbs, and been spared pain and a long confinement to a sick-bed; and millions will yet share in these benefits, for the principles of the antiseptic treatment of wounds will *never* again be abandoned as long as the whole of our knowledge is not lost, no matter how our art or the points of attack may change. Perhaps we may some day succeed in treating injured limbs simply in heated or filtered air, or may learn to strengthen the living power of resistance of the tissues and organs so that they can of themselves resist the action of those invisible enemies. The protection afforded by vaccination makes it appear possible that in this direction also new paths are opening out to us.

England may be proud that it was one of her sons whose name is inseparably connected with this the greatest advance that surgery has ever made. Without envy other nations may yield her the crown. For the long and silent labour which made the ripening of the seed possible, which we now reap so quickly and fully, was quite international, and especially France and Germany took part in it in an equal degree. Nor did any one more fully recognize the importance of those who worked before him than Mr. Joseph Lister.

Moreover, it has happened with the discovery of the antiseptic method as with so many great discoveries; years, sometimes centuries, prepare them, they are in the air as it were, until one day, to the surprise of mankind, they suddenly seem to fall down from heaven. Nothing is more instructive than to reflect the

light of our present knowledge on the endeavours of past times, and to see how since the beginning of this century the most heterogeneous opinions have been held concerning the treatment of wounds; how methods apparently the most opposite have been employed, in all of which we may, however, now recognize a certain value—how wounds were treated with ice, with the cautery iron, with alcohol; how they were ventilated or hermetically closed; how the subcutaneous mode of operation was resorted to without deciding the question why the air coming into contact with the injured tissues of the body in one series of cases causes such deleterious results, in others appears perfectly harmless; how, seeking without any firm leading principle, experimenting and often abandoning one's self to the rudest empiricism, yet the goal was approached nearer and nearer—so near, that we might suppose it was almost possible even then to grasp the truth, and that every one ought to have recognized it, and then, when daylight is approaching, and even when the chief problem has been solved, that then the complete failure of our art was shown by the adoption of the open treatment of wounds.

I consider the directions given by Stromeyer and Pirogoff, especially for gunshot wounds, and in their time perfectly justified, never to probe a fresh wound, is here carried out to actual nihilism, and, to our shame, proofs are given that with passive looking on and the renunciation of quick healing by first intention, with good cicatrizing, the results were on an average better than in all active methods of treatment practised up to that time. Gentlemen, I wish not to be misunderstood. I do not mean that open treatment of wounds which is at this day employed in the most efficacious manner in combination with strictly antiseptic measures where the locality or serious disturbances already caused in the wound do not permit of the usual appliances, or where after an operation performed with all the means of protection which modern surgery affords us, we may so safely count upon a healing by first intention that further measures seem unnecessary. I will also point out that the German surgeon who first employed the open treatment of wounds and gave it its name, and achieved excellent results with it—Burow—introduced in connexion with it a remedy which we now know as one of the strongest antiseptics—*i. e.*, the argilla acetica. But I speak of that open treatment of wounds which, rejecting all the attainments of modern surgery, was so emphatically lauded as a special method to be preferred to all other modes of treatment.

Gentlemen, in speaking of the open treatment of wounds, I have touched on the opposition which the new doctrine at first met with on so many sides. You all know well how violent this was. Even in science great changes cannot be brought about without injury to numerous personal interests. But I insist that nowadays no serious opposition exists, that there is no surgeon who would dare at the operating-table or in the treatment of the wounded quite to renounce antiseptic methods; who calmly and with a good conscience would tread the paths in which fifteen years ago we all followed like cattle. Even the most obstinate have had to give way to the great principles of the new era, and often in a much higher degree than they acknowledged to themselves or others; the necessity not only of the disinfection of hands, sponges, instruments, and bandages, but also the necessity of a primary disinfection of fresh wounds, is, I believe, universally acknowledged.

In this respect, then, the time that we have lived through stands alone. In a period of a few years a new revolutionizing doctrine and a new difficult method of treatment which increases to the utmost the responsibility of the surgeon treating the case has celebrated its triumph through the whole of the educated world.

I hope you will think it natural if I, in the attempt to sketch the most essential

points by which modern surgery differs from that of past times, place in the first ranks the immense diminution of mortality after serious operations and severe injuries. It seems natural to prove the advances made in this respect by comparing the mortality under the old surgery with that of the present day. But in spite of all trouble and labour, the only result of such attempts is the conviction that our present results are incomparably better. How great used to be the average losses caused by important operations and serious injuries we shall never learn. One thing is certain, that they were much greater even than most of the available calculations made them appear. But this second fact is just as certain; that the calculation of averages had at that time scarcely any value, because the mortality was subject at different times, in different hospitals, and under different surgeons, to the most enormous variations, as a glance into the celebrated work of Malgaigne will show. Average numbers can only be of value when the variations take place within certain fixed limits. The high tables of mortality of old surgery have been obtained by the addition of series of cases which differed from one another fivefold or tenfold; and as soon as they were applied by the sick-bed or in the judgment of the results of treatment, they let any result appear satisfactory, and, if fatal, excused it.

We may therefore say without exaggeration that the old statistics of surgery were of no use, but only did harm, and we may oppose to their sad, unsatisfactory figures the simple demand that *no* person should die of an injury unless its severity directly threatens his life, and that no person injured or operated on should perish through a secondary inflammatory disturbance developed from the wound. Every loss of this kind may be traced to some mistake on our part.

But we, who have ourselves groaned beneath the weight of the old surgery, and have now made the new our own, possess comparative statistics that are infinitely more valuable to us than all those that our opponents have held up against us, statistics which we have fought for in the last few years. The time is long enough to have excluded all the old theories of chance. During ten years it is not possible to be always lucky, always to have good cards, as even Pirogoff still ventured to assert of certain privileged surgeons.

And if we compare our former with our present results we find a difference like that between day and night, the feeling of a great victory after long and severe defeat; and never do I feel more solemnly and gratefully inclined to Providence, who has permitted me to live to see this blessed change, than when I make this comparison.

Professor Nussbaum has drawn this comparison between then and now in his clinic in clear traits and with manly candour; he has shown that for forty years, under his own direction as well as under that of his predecessors, among whom was Stromeyer, fatal wound diseases raged, that nearly all patients with compound fractures died of them, and that even those with the slightest injuries often succumbed to them; that erysipelas and abscess were matters of daily occurrence, that during the latter years hospital gangrene also appeared and attacked the dreadful number of eighty per cent. of all wounds and sores, that he stood helpless and powerless before all these conditions, and that at one step, after the general introduction of the antiseptic method, all this ceased, and instead, even after great operations, healing by first intention was introduced as an entirely new result.

I have also tried already at the third German Congress of Surgeons to draw a similar comparison; it is not essentially different from Nussbaum's. Since then many years have elapsed; and in all countries, but perhaps most of all in Germany, a great mass of experience has been collected, and it might perhaps be now possible by a comparison of large numbers to discover with some amount of

certainty what is really the chief question; how far we have got in the control of accidental wound diseases; what dependence is to be placed on our present technical aids; where and how often they leave us in the lurch, and where the limits to our present power are placed. Time and place do not permit me to make this attempt, and perhaps it would be beyond my power. But, with your permission, I will lay before you some data bearing on these questions, and if I take these chiefly from my own experience, you may be convinced that this is only because these are most accessible to me, and because I can myself vouch for their accuracy. For the satisfaction of personal vanity I should probably have chosen another subject than this which shows what can be achieved by a method in the invention of which I had no share, and should have brought forward other results than those which were only achieved by submitting entirely during the first years to the prescriptions of Joseph Lister, and resisting every temptation to do better and more simply than he. Most of the unfavourable judgments passed on this method are due to the fact that surgeons who had not yet learnt to experiment *with it* already made *it* the subject of their experiments.

Two examples will suffice, compound fractures and major amputations. The mortality after compound fracture had, during the long labours of my predecessor as well as during my own, reached the sad height of forty per cent. When I adopted the antiseptic treatment of wounds my last twelve patients, with compound fracture of the leg, had all died of pyæmia or septicæmia. From that time up to the present day I have treated one after another 135 compound fractures, and not a single patient has succumbed to either of these accidental wound diseases; 133 were cured, two died, one of fat-embolism of the lungs, during the first few hours, and one, a drunkard, of delirium tremens.

For amputations one assertion will almost suffice, which I beg you to regard seriously; I now cure every year more cases of amputation of the thigh than during all the rest of my labours before the introduction of the antiseptic method. The number of the amputations of the larger limbs which I have undertaken during the last few years amounts to more than 400. If I subtract those cases where death did certainly not result in consequence of the operation, but independently of this from some other serious complication, there results a mortality of four to five per cent., and the same number, as far as I can discover from the communications before me, was obtained in the other German hospitals in which antiseptic surgery is practised in full strength.

My friend Dr. Schede has made a calculation which will, I believe, interest you. He has studied the reports of a great number of amputation cases of the old period, so that he was able to distinguish those in which death resulted from pyæmia or septicæmia—those therefore which we now save—and the mortality of the remaining cases also amounted to about five per cent. In these four to five per cents., besides those fatal cases caused by mistakes in treatment, those are also included which in amputations after serious injuries must be laid to the door of the shock caused by the previous serious loss of blood. We may therefore declare that amputation of the larger limbs has been almost absolutely free from danger—at any rate, much less dangerous than many small operations were formerly, whose mortality was never discussed. After extirpation of sebaceous cysts in the head, occasionally one or other of those operated on perished; and a by no means small part came off only with their lives. It is true, I must not disguise the fact, that my numbers have been slighted. It has been said that I kept back the unfavourable cases, and thus improve my figures of mortality. Quite lately a French colleague of mine declared that in France it would not be possible to agree to my sort of statistics!

But, gentlemen, what do we want? Do we want to count the amputated

limbs like fallen apples, which are picked up from under the trees? Or do we want to gain figures that answer questions which have a practical importance? If we want to know how dangerous *per se* is amputation at the upper part of the thigh, we cannot learn this from the patients who already suffer from severe septicæmia, or who, besides, suffer from severe brain injuries; and if we want to know how dangerous it is to remove *one* thigh, we cannot make use of cases where both have been amputated. But I will not complicate these statistics in order, as my opponents say, to contrast the most favourable with the most conceivably unfavourable cases. During the time of which I speak 57 large limbs were amputated—lost according to common parlance—because of acute progressive septic processes, chiefly patients with severe open fractures, wounds of the joints, and laceration of the soft parts, who were brought to us too late from the country, cases of embolic mortification and large putrid abscesses. All patients in whom signs of mortification had shown themselves, were not counted. Of these 57 amputated cases, in which, in almost half the cases, the operation concerned the thigh, fully 70 per cent. were cured. A mortality of 30 per cent. is lower than I formerly attained to in cases of primary amputation. It shows best how erroneous are the views of those who contend that antiseptic surgery can only attain results in prophylaxis. Far more rapidly than by means of figures and a survey of successes, we can attain to a comprehension of the enormous advance achieved by modern surgery when we see what is actually done in the domain of operations—what is held permissible, and what is done and risked daily without danger to the patient. For this it is not needful to be a surgeon, not even a doctor, in order to testify to the changes that have come about. Operations are now conducted which fifteen years ago would have been regarded as madness, or as crimes. And often it is the younger doctors who have not had much experience of independent practice who have this advantage over their more venerable colleagues—that they have faith in the infallibility of the antiseptic principle, and have a courage that has not yet been daunted by ill-success; and it is they who venture upon operations of which formerly the most daring surgeons did not think, and attain results concerning which these shake their heads.

But do you think, gentlemen, that one of us older ones could so easily take up the idea of Ogston's operation? For this one must be young, and have grown up in the new thoughts and surroundings, and only know the sad experiences of older surgery as a legend. It is far from me to wish to discuss the value of the operation for the cure of genu valgum. I only wish to show from what one does not shrink. It will always remain of historical interest that, a few years after a great war, in which we were obliged to let the greater number of our wounded die in whom a ball had pierced the knee-joint capsule without hurting the bones; we dared to saw off in the dark within the joint a condyle, leaving blood and sawdust behind. Further, it would be easy to produce numbers of as apparently venturesome operations of which no one doubts the necessity or that they should be permitted.

For a large enchondroma in the costal pleura that occupied the left wall of the thorax, Professor Fischer removed a large piece of the chest-wall and ribs, so that the heart and lungs were exposed and an opening as large as a child's head was made, and yet the patient was able to be discharged from the hospital after four weeks.

In the case of a large echinococcus of the liver, which in front and at the side was covered with thick layers of liver tissue, and which projected into the thoracic cavity after resection of the seventh rib, I opened the healthy pleural cavity, which was free from adhesions. The thorax was freely open, the thin diaphragm cut into, the echinococcus sac opened, the animal bladder extracted *in toto*, and

the patient recovered without complication. A similar operation, with like results, was conducted by Mr. Israel of Berlin. Mr. Hahn, also of Berlin, in two cases of wandering kidney, where the mobility and the discomfort induced thereby had attained an unusually high degree, drew out the organ in question through a large wound in the loin, and sewed it into the same. Both patients recovered and lost their pain. The opening of the joints seems a most innocent performance. Hips and knees are cut open in order, in a case of luxation, to search for the obstacle which opposes itself to reduction, in order to suture the ruptured tissues, and in obscure symptoms to clear up the diagnosis *in vivo* by means of autopsy. More than two hundred times I alone, without in one instance bad results following, have incised, drained, and washed out diseased knee-joints without exciting suppuration.

Bone and marrow tissue will submit to every kind of treatment without putrefying and without suppuration. Orthopædics celebrated their greatest triumphs in the saving and straightening of limbs. We read that Mr. McEwen alone has performed 835 osteotomies, of which 827 were healed without suppuration, and he lost no patient from the operation itself or from its consequences. To facilitate the healing of empyemic cavities, Mr. Schneider resected from six to nine ribs, and even also the clavicle. In very painful cases of syphilitic hyperostosis I myself have repeatedly exposed the tibia in its whole length, and knocked off with a chisel a whole handful of bone shavings. The cure was rapid; the pains disappeared. The old opinion that in cases of strumous suppuration wounds heal less well has been set aside—the largest scrofulous abscesses, even if they come from the spinal column, can be opened not only without danger, but often healed in a brief time through a special kind of first intention. The feat of excision of part of the stomach has excited the whole world, perhaps to excess, since the same operation has been already effected upon the intestines with the happiest results. Weak, paralyzed persons, who usually are anxiously shielded from every injury, have had their main nervous system exposed, to subject it to thorough manipulation.

And now leave the writings and let us realize the teachings of the greatest masters of the first half of this century, of those who were equally great as doctors and as men; for instance, Sir Astley Cooper, whom we may regard as the representative of the highest development of the older surgeons, and you will be convinced that their firm and leading principle, the moral standpoint on which they stood was this, that every operation is dangerous, and should if possible be avoided. There is not one of us who, led by B. von Langenbeck, did not stand on the same ground during the great wars of 1866 and 1870, in his treatment of the wounded. Only since 1870 the new views have forcibly made their way.

Cast a glance at the surgical clinics of hospitals, where these are conducted by men who have willingly given up the hardly won results of their own work, and have entirely adopted the knowledge and power of our new art, and here too you will see the greatest changes; cases of operations and wounds without fever and pain, a happy result being regarded as certain; no traces of blood and wound secretions on the bandages, let alone on the body and bed linen; disappearance of that incessant activity of untrustworthy and senseless assistants, the continuous putting on and taking off of compresses and cataplasms, the regular change of bandages repeated every morning and evening. It would thus appear that in association with anæsthetics and the bloodless method, antiseptic surgery has deprived all important operations of their terrors. Certainly the preparations for an operation are often tedious, the first cleansing and preparation of a fresh wound circumstantial and lengthy, but with the first dressing an immense amount of work has been obviated, which formerly extended over the following weeks

and months. The later course, the fate of the wounds of the patient, is as a rule determined and assured by this first dressing; we can often heal an amputation wound with one or two dressings.

Our views on the nature of contagia in the surgical department of hospitals, on their origin and breeding places, have entirely changed. There is no hospital that is so bad that it can excuse failure in the treatment of wounded and operated patients. If we had no other task in the treatment of our sick but to guard against the purely relative interruptions of the normal process of wound healing, we could be content with the old close and over-filled houses, and the splendid piles we now erect would be superfluous. We well know plague-stricken hospitals, where, from wound to wound, from sponge to sponge, from compress to compress, fungous formations in countless generations have grown to the highest degree of adaptation to the fluids and wound secretions of the human body. But it lies in our power to disinfect them. By no ventilation in the world can septicæmia, pyæmia, and erysipelas be blown out of the hospitals; not even by the most assiduous care in ordinary life can they be avoided, but only by the conscientiousness and prudence of the surgeon. If ever the excellent Simpson was right in his assertion that far more operated patients die in hospitals than in private practice, modern surgery may rather declare the contrary. If there is any danger of a mistake in the treatment of a wound, it is more likely to happen in a private house where it is more difficult to satisfy the accurate demands of modern surgery than in the hospitals.

Gentlemen, weighty circumstances and daily occurences have always made surgeons as well as laymen recognize the importance of those problems which are solved by the discovery of the mycotic nature of wound diseases. The contrast between open and subcutaneous wounds must have been known as long as men have worked hard and have fought each other with weapons. And not only was this known, that simple fractures are not dangerous and heal without suppuration, but also the experience had been gained that there will be no suppuration, no matter if the individual concerned is young or old, robust or decrepid, scrofulous or syphilitic—whether he has this or that constitutional condition, this or that individual disposition. And this also has long been known, that the danger in a compound fracture is very great; if only on the lower thigh the skin, very poorly supplied by nerves and vessels and scarcely for an inch in area be sharply perforated by one of the fractured ends. But the consequences of these facts were not seen. They were too much opposed to the prevailing doctrine which regarded not only the suppuration, but also the serious disturbances resulting from it, as only *quantitative* increase of the process of reaction following on the injury. The whole of antiphlogistic therapeutics was based on this supposition. And yet the history of fractures might long ago have afforded the most conclusive proofs that it could not be the intensity and extent of the injuries of the tissue which determine the severity of the inflammation and the suppuration, that these latter had in reality nothing to do with the traumatic reaction, but must be some other thing essentially different. For even a good number of simple fractures are by no means such simple things as was formerly imagined, since they often do not occur without serious crushing of the marrow, tearing off of the periosteum, laceration of muscles, fissures, and splinters; certain forms of fracture, especially those of the cervix femoris, and of the spine, are good examples of destruction and crushing of the tissues. And yet even in these cases, suppuration of the greatest intensity does not occur. To attain the conviction that mechanical obnoxious influences, however severe, cannot of themselves produce suppuration, no myologic examination would have been required. The importance of this fact was only revealed to me in its full bearings in examining the wounded on the

Bohemian battle-fields. Among the great number of gunshot fractures which I had to treat there, there was a not inconsiderable number of cases where cure resulted after the usual course, as after a subcutaneous fracture without suppuration and without discharge of splinters; and I considered it obvious that here only that explanation was admissible which Stromeyer had given to these cases —namely, that the ball, passing at a tangent, had broken the bone flat, as in the simplest subcutaneous fracture. But of those so successfully cured, two of those who had been injured in the upper part of the thigh died from the results of other wounds inflicted at the same time; and when I examined these supposed bone-fractures, I found to my surprise that just here the most extensive destruction had taken place. In the one case twelve splinters, in the other about twenty, of a size varying from several inches to that of a pea, were caked together by fresh callus without any suppuration or necrosis, and in another similar case there lay firmly inclosed in the callus a little piece of cloth from the uniform.

Then, in the year 1870 Professor Klebs discovered that even in the internal organs, which are considered so vulnerable—as brain, lungs, and spleen,—no inflammatory reaction occurs, if the path of the bullet is so long and narrow that it prevents the admission of air; and that even weeks afterwards, macroscopically, no changes can be traced in the tissues shot through, while microscopically the process of healing can only be recognized by a minimum of cellular activity.

And now antiseptic experiments which exclusively belong to Mr. Joseph Lister, to whom I therefore here offer a small part of the gratitude that German surgery owes him, show us that, after an amputation, on the fourth or sixth day the ends hang down in just as limp and unchanged a manner as immediately after the operation, just as if it had been performed on a dead body and not on a living being; that after a great plastic operation, in spite of countless sutures, no trace of œdema or reddening, and no pain, occur. India-rubber tubes passed through dropsical joints may remain lying there for weeks without causing suppuration, and they may, slipped unnoticed into the cavity, heal so firmly into the armpit that a year after they may be mistaken for well-defined cancer tubercles, and be extirpated. Into the open peritoneal cavity a piece of gauze larger than a table napkin, and pressed together like a handkerchief, can be put, and remain for several days, without fever or clinical appearances of fever resulting. And I should like to mention one more experiment, which, it is true, will not always succeed. Suppose we have a case of limited fistulous caries of the foot before us; five or six times we introduce the glowing Paquelin cautery iron to the depth of an inch and a half, and carbonize the dissected tissues. Then we cut the skin in a circle round the former fistula at a breadth of two lines, and let the blood, mixed with a disinfecting fluid, flow into the deep spherical cavity, fill it out, and coagulate. In a fortnight or three weeks the upper layer of the coagulum scales off and the burn is cicatrized without any reaction, suppuration, or falling off of the scab. So that in man also Professor Hueter's five experiments on animals are confirmed.

After such facts there can be no further doubt that we have hitherto studied traumatic reaction of open wounds on tissues infected at the same time that the four cardinal symptoms of inflammation—robor, calor, tumor, dolor, even in the severest open wounds—are not developed when disturbing agencies have no access, or do not find soil fitted for their development.

Seriously, we have now to consider the question whether mechanical irritations, such as the surgeon's knife and saw cause, and the injuries of the social life, are at all capable of alone bringing about those processes which have at all times been designated as inflammatory.

I do not consider this latter question as yet fit for decision, although the ex-

treme radicals already advance weighty reasons to refuse even to thermic and chemical irritants the power of causing inflammation; so long as in the erythema of burns and the dermatitis from iodine painting associated with abundant exudation of leucocytes the influence of organic germs is not proved, and so long as the same proof is wanting for carbolic erythema, I believe that we ought at any rate to wait for the results of further investigations.

Gentlemen, I have touched on traumatic reaction of the tissues to show how distinctly modern times have influenced even the oldest dogmas of our science; how we are obliged to abandon almost everything that our schools have taught us in order to gain for our scientific opinion a newer, firmer foundation.

I am coming to an end. I have already occupied your attention for a longer time than may appear fitting to some of you. I have spoken of the advances in surgery. There is one I have not yet mentioned. It has never hitherto been so deeply and universally realized that the interests of our practice must coincide entirely with those of our patients; never before was the feeling of responsibility for our actions so great as at the present day. The breach which divides us from the older surgeons is immense here. We do not refuse to let our capability be entirely measured by our successes. For even if the surgeon of former times willingly submitted to this measure, when it was only a subcutaneous fracture without essential displacement or the straightening of a club-foot that was to be dealt with, yet, as soon as it was a matter of preserving life after an operation, or even of preventing serious disturbances, he might decidedly reject this standard. No surgeon, however learned and skilful he might be, would have been willing then to promise or guarantee, or in case of ill-success to reproach himself; he is almost certain in this important point to have, like every other surgeon, the sad privilege of not being responsible for uncontrollable circumstances.

To-day we may say with the deepest conviction that the surgeon is responsible for every disturbance that occurs in a wound; that it is his fault if even the slighest reaction or redness is developed in it, or if an amputation is not healed by first intention. He must reproach himself severely if after an operation bagging of pus occurs, and especially if death occurs from pyæmia. He who cannot attain to this degree of perfection may be converted from his former method of treatment to antiseptic methods like one who, having hitherto always prescribed senega for catarrh, now uses ipecacuanha. Of the storm that has swept over the fields of surgery during the past ten years he has not experienced a breath.

Justice requires us to recognize that the higher moral aspect of this question has come to us from England. It was the English ovariotomists, with Mr. Spencer Wells at their head, who first showed us how to approach an operation at that time looked on as fatal, how to take on one's self the whole responsibility of success or failure, and to keep no other goal in view than this one, to save the patient, and, by a constantly improving and perfecting of our art and carefully keeping everything injurious at a distance, gradually to become more and more master of one's actions. At that time we began to recognize that at the operating-table there are other matters of importance than to shine by quickness, elegance, and security in the use of the knife.

Yes, gentlemen, our labours have become more blessed and more joyful. We know that a great responsibility rests upon us, but we also know that with honest will, knowledge of our subject, and use of all our powers, we are able to satisfy its demands. And because we believe that this feeling of responsibility is living and constantly increasing in the younger generation, we trust that surgery will overcome the dangers that doubtless lie in the rapid changes it has experienced, and is being led towards a further development.—*Lancet*, Aug. 13, 1881.

MONTHLY ABSTRACT.

Anatomy and Physiology.

An Experimental Inquiry into Human Milk, and the Effects of Drugs during Lactation on either Nurse or Nursling.

Mr. THOMAS M. DOLAN and Mr. W. H. WOOD commence, at p. 85 of the *Practitioner*, for 1881, a series of interesting papers on this subject, undertaken by Mr. Dolan in order to answer the frequent question, "Will my medicine have any effect upon the child?" That medicines and foods do affect the milk, and consequently the child, is certain. Frequently, a wet-nurse, on her first arrival, causes the child to thrive; but soon all becomes changed, because, from a laborious out-door life, with few luxuries, the woman is surrounded with good living, and has very little exercise, and consequently her milk ceases to nourish the child. Cause her to resume, as near as possible, her former mode of life and food, then her nursling quickly recovers. A clear description of the best method to analyze human milk is then given, which is, however, too long for insertion, and cannot be condensed. The practical outcome of these elaborate papers is summed up at page 337. 1. All therapeutical agents intended to act on the mammary gland must first enter the blood. 2. All drugs derived from the natural orders Liliaceæ, Cruciferæ, Solanaceæ, Umbelliferæ, etc., enter the blood and impregnate the milk, hence caution is needed in giving such drugs to nursing women. 3. The only approach to a true galactagogue is jaborandi. 4. Belladonna is an antigalactagogue. 5. In inaction of the mammæ, the milk may be increased and influenced by medicines. 6. The milk of the mother may be increased in heat-forming elements by the administration of fats. 7. The salts of milk may be improved by the administration of medicines. 8. Various physiological actions—purgative, alterative, diuretic, etc., may be produced in the child by administering drugs to the mother. 9. If we are to expect any improvement in milk-secreting power, both as to quantity and to quality, we must look to diet for the attainment of that object.—*London Med. Record*, July 15, 1881.

Materia Medica and Therapeutics.

Pilocarpin.

Dr. WILLIAM SQUIRE read a paper at the London Congress on the physiological action and therapeutic use of pilocarpin, which is the alkaloid obtained from the leaves of jaborandi, on which the efficacy of that drug, long known in Brazil, in producing sweating and salivation, depends. Another alkaloid, of different, and even antagonistic properties, named jaborin by Harnack and Meyer, coexists with it, and renders the infusion or tincture of jaborandi less certain, and perhaps, less safe than that of the pure alkaloid. It is possible that pilocarpin itself has not always been obtained quite free from admixture with its associated but antagonistic jaborin. Muriate of pilocarpin, in simple solution, is the best form to use —1 grain to 15 minims of water for hypodermic injection—1 grain to 4 ozs. of water for internal use are convenient proportions; ½d grain is the largest, $\frac{1}{15}$th of

a grain the smallest dose needed. Mr. S.'s plan is to give a full dose at once; others give small doses every hour with some warm drink or alcoholic stimulant, till perspiration and salivation are freely established. A drachm of the tincture, made with 30 grains of leaf, is equivalent to ½d of a grain of pilocarpin; ¼th of a grain of the muriate, injected hypodermically, will in a few minutes produce suffusion of the face, quickened pulse, some throbbing in the neck, and a general feeling of warmth, followed by free perspiration; this is soon streaming profusely from all parts of the surface, and continues long after the skin has become pale, or even cool; the pulse subsides, while the force of the heart's impulse is rather increased; there is a tendency to sleep, and generally a fall of temperature; the perspiration goes on for three or four hours; there is an increased flow of saliva, and some increase of pharyngeal, and sometimes of bronchial mucus, that may give rise to trouble during sleep, and require attention; such a quantity of saliva may be swallowed as to excite vomiting. No headache, sickness, or depression has been noticed by me as a direct result of this medicine. All the secretions of the body, except the intestinal, are increased by it; the quantity of urine, hardly lessened during perspiration, is increased afterwards. Dr. S. has not met with dysuria. Swelling and tenderness of the submaxillary salivary glands has remained for a day or two after profuse ptyalism. The action of the drug is on the peripheral secreting apparatus, and not on the nerve centres, except so far as the first action on the vaso-motors may dilate the vessels, and allow the agent freer access to the glands.

Atropia is directly antagonistic to it in this respect. Aconite dilates the vessels, but weakens the heart, while pilocarpin, having no such effect, may even allow of small hemorrhages occurring. It is not anæsthetic. The perspiration induced by it does not relieve dysmenorrhœa, sciatica, or colic. Pilocarpin does not moderate specific fevers; but given near the time for the separation of the false membranes in diphtheria, it aids the fall of temperature, and favours sleep. Where there is already a tendency to collapse, of course it can do no good. It is useful in the febrile relapse of scarlatinal nephritis. Dr. S. has met with no confirmation of the observation that small doses ($\frac{1}{20}$th of a grain) will check perspiration; a similarly homœopathic view, that particular diseases must have particular remedies, has led to the statement that pilocarpin is unsuited to renal disease. The use of it has been chiefly in the different kinds of Bright's disease; it may be unsuited to that particular form where dilated vessels and diminished blood-pressure are associated with a large quantity of albumen; yet, in these very cases, it is serviceable to the intercurrent exacerbations and conditions of accidental congestion, not infrequent in their course, and it is preferable to the hot pack, or vapour bath. In the early stages of interstitial nephritis of gouty origin it is of great benefit; in the chronic course which these cases generally follow, it is often useful; it may be resorted to in some of the extreme effects of renal dropsy, and the relief obtained is not accompanied by great depression. In the chronic results of parenchymatous nephritis, as after scarlet fever, it has been found useful; and that it need not be withheld in some cases of scarlet fever itself is proved by the remarkable results obtained from it by Guttman in the treatment of the allied disease diphtheria.

—

Physiological and Therapeutic Action of some new Active Principles (Pelletierine, Valdivine, and Cedrine).

Dr. DUJARDIN BEAUMETZ was the author of a paper with the above title, read at the London Congress, of which the following is an abstract:—

Pelletierine is the alkaloid obtained from pomegranate-bark. It was discovered by Tanret, on the 26th of August, 1878. Its name commemorates the services of the French chemist, Pelletier, the discoverer of a large number of alkaloids

and, in particular, of quinine. Pomegranate root contains a series of alkaloids: Pelletierine ($C_{16}H_{15}NO_2$), Isopelletierine ($C_{16}H_{15}NO_2$), Pseudopelletierine ($C_{18}H_{15}NO_2$), and Methyl-pelletierine ($C_{18}H_{17}NO_2$). The author has investigated the action of all the above alkaloids, more especially of the sulphates of pelletierine and isopelletierine.

To the lower animals these alkaloids are speedily fatal. Rabbits are killed by a dose of 0.15 to 0.20 centigramme; frogs, by the hypodermic injection of one or two drops of a solution of one in ten. These effects are due to a paralyzing action upon the motor nerves, on muscular contractility, and on sensibility. The alkaloids are "curarizing poisons;" there is no difference between a curarized frog and one poisoned by the salts of pelletierine.

In the human subject, the sulphate of pelletierine, or of isopelletierine, administered hypodermically in a dose of from 30 to 40 centigrammes, gives rise to motor paresis with vertigo; the latter being due to well-marked congestion of the fundus oculi, and of the whole encephalon.

Pelletierine has been chiefly used as a remedy for tape-worm. The author and M. Bérenger-Féraud have shown that, of the four alkaloids, pelletierine and isopelletierine alone are endowed with tænicide properties. The author prescribes the sulphate of pelletierine in combination with tannin. A mixture of 30 centigrammes of the sulphate, in a solution containing 90 centigrammes of tannin, is given on an empty stomach; this dose is followed by one of 30 grammes of compound tincture of jalap. This treatment is followed by the expulsion of the tape-worm, with its head, in a majority of cases (9 out of 10). The above dose is only suited for adults. Children about thirteen years of age should not take more than 0.15 centigramme of the sulphate of pelletierine, and infants not more than 0.10 centigramme.

The author has prescribed pelletierine with success in Menière's vertigo; he recommends it in all those cases in which curare is indicated (tetanus, rabies) and in those ocular affections in which it may be necessary to excite rather active congestion of the fundus.

Valdivine and cedrine have been extracted by Tanret from cedron seeds. Of these seeds there are two distinct kinds, which have hitherto been confounded with each other. One of them is derived from the simaba cedron (Simarubaceæ), the other from the valdivia, also a simarubaceous plant, but which belongs, according to Planchon, to the genus picrolemma (picrolemma valdivia). Both of these species grow in Columbia.

Valdivine ($C_{16}H_{24}O_{20}.5HO$) crystallizes in hexagonal prisms. It is not, strictly speaking, an alkaloid, but a glucoside, not entering into combination with acids. It requires 30 parts of boiling water for its solution. Its bitterness is intense.

The author has investigated the action of this substance together with M. Restripo. It is extremely poisonous, a dose of 0.002 milligramme being sufficient to cause the death of a rabbit in ten hours. Increase of dose does not much increase its toxic activity, which appears to be greater in proportion to the place of the animal in the scale of organization. Thus, frogs are not susceptible of the poisonous effects of valdivine.

In the human subject, a dose of 4 milligrammes, given subcutaneously, excites vomiting in from one to two hours.

The administration of valdivine in cases of intermittent fever, snake-bite, and rabies, yielded negative results in all save the last-named affection. Experiments made at the veterinary school of Alfort showed that a dose of 4 milligrammes of valdivine administered to rabid dogs abolished the paroxysms, without, however, preventing the fatal issue of the disease.

Cedrine has been extracted from cedron seeds. It was first described by Lewy,

who seems, however, to have confounded it with valdivine. Cedrine has not been crystallized. It is much less poisonous than valdivine, 10 milligrammes being required to kill a rabbit in forty-eight hours.

Cedrine does not cause vomiting. Subcutaneously injected, in doses of from 3 to 5 milligrammes per diem, it exerts a real influence on intermittent fever. But its activity is inferior to that of sulphate of quinine.

Against rabies and snake-bite cedrine is absolutely devoid of efficacy.

Medicine.

Connection of Chorea with Rheumatism.

Prof. STEFFEN, of Stettin, made some interesting remarks at the London Congress, on this subject, of which the following is an abstract:—

A definite interdependence between chorea and rheumatism is not as yet proved. That both of these morbid states are often joined with endocarditis cannot be used as evidence of such a connection.

The relation between chorea and endocarditis cannot be fixed anatomically or pathologically. Probably the chorea is always the primary morbid phenomenon.

The chief symptoms of acute endocarditis are active fever, dilatation of the heart, with enlargement of the area of dulness, a systolic blowing murmur, and an accentuation of the second sound in the area of the pulmonary artery. The dilatation precedes the murmur, if the endocarditis has originally or exclusively attacked the heart walls. In primary inflammation of the valves the opposite takes place.

When an endocarditis which exclusively involves the heart-walls recedes, the dilatation of the heart disappears first, and then, gradually, the blowing murmur. If the valves are also attacked, the systolic murmur remains after the dilatation has disappeared. Dilatation and hypertrophy may afterwards develop afresh as a secondary process.

Acute dilatation of the heart is observed without endocarditis in grave and acute obstruction of the pulmonary circulation, and in septic processes.

Cardiac murmurs occur in chorea without endocarditis. These depend on impaired function of the heart, not only through nervous influence, but also through the obstruction to the circulation of the blood, which occurs as a result of the spasmodic movements of the body.

The Modifications of Syphilis in the Tuberculous, Gouty, and other Constitutions.

At the London Congress M. VERNEUIL, of Paris, read a valuable paper on this subject, of which the following is an abstract:—

Syphilis may coexist with any other constitutional taint. There is often simple coexistence of the two conditions, but not unfrequently one has an important influence on the other.

Though referred to by Hunter, Ricord, Revillet, and others, there is, at present, no complete work on syphilitic hybrid disease.

The author's observations have been principally directed to hybrids between syphilis and scrofula and syphilis and cancer.

Scrofula usually precedes syphilis, and exerts an influence upon it; but, occasionally, syphilis in a youth or young adult, brings out struma which has been latent from infancy. Scrofula attracts syphilis to the organs it most commonly itself affects, skin, glands, periosteum, etc., and is apt to set up suppuration in

these, a result not common in simple syphilis. Scrofula modifies secondary and tertiary syphilitic ulcerations, so as to make the diagnosis often difficult. It does not aggravate syphilis, but perhaps renders its local manifestations more permanent, while, as a rule, it removes the element of pain.

Tuberculosis, on the other hand, if it does not actually favour the occurrence of severe and intractable syphilitic lesions, certainly makes some tertiary manifestations persist indefinitely. Stricture of the rectum, for example, is commonly complicated with pulmonary tuberculosis.

In treating such conditions, it is well to combine antiscrofulous with antisyphilitic remedies, but, on the whole, the indications are similar in the two diseases.

When cancer is combined with syphilis, it is the former which is modified by the latter. The cases are rare. There are hardly any which prove the existence of the opposite condition. The author has seen cancer attack a testicle in which a gumma had existed which had been cured two years previously, no doubt a *locus minoris resistentiæ*.

The diagnosis of such hybrid cases is difficult. Enlargement of the lymphatic glands favours the idea of the existence of a new growth. The almost complete indolence which is so frequently noticed, and the comparative benignity of these cases, are due to the syphilis; but the constant advance, the infection of the system, and the fatal termination depend upon the new growth, the latter always asserting itself at last. In doubtful cases, antisyphilitic remedies should always be tried. They sometimes produce remarkable improvement, and raise the hope of a cure. This temporary arrest of the growth may well surprise when it is remembered how useless, if it be not actually harmful, is the administration of mercury and iodide of potassium in ordinary cases of epithelioma or cancer.

On the Röle of Syphilis as a Cause of Locomotor Ataxy.

Prof. W. Erb, of Leipzig, in a paper read at the recent International Medical Congress, said: "My own recently published statistics on 100 new cases of typical tabes in male adults (*Medicin. Centralblatt*, 1881, Nos. 11 and 12), showed:—

	Per cent.
Cases *without* previous infection	12
Cases *with* previous infection	88
(Amongst them, *with secondary syphilis*	59
And *with chancre, without secondary syphilis* . . .	29)

(Up to to-day—June the 1st, 1881—I have observed 13 further cases; amongst them there is *but one without* previous infection; of the remaining 12 eight have had secondary syphilis, four only a chancre; the proportion in these cases is, therefore, still somewhat more unfavourable.)

With regard to the *time of appearance of the first symptoms of tabes after infection*, my cases show, that by far the most occur from the 5th–15th year after infection; a considerable fraction, however, occurs 3–5 years after infection.

In order to control these statistics, I have made a *counter proof* extending over all male adults over twenty-five years old, of my clientèle, who do *not* suffer from tabes, and not directly from syphilis. I have carefully examined up to to-day nearly 500 persons with regard to this question, and I find præter propter:

77 per cent. were *never infected.*

12 per cent. who had formerly *secondary syphilis;* and

11 per cent. who had only a *chancre.*

The simple confrontation of these facts is forcible enough, and convincing for every one who does not shut his eyes purposely. The only possible logical conclusion from these facts is *that there must be a certain etiological connection between syphilis and tabes.*

The remark which has been made repeatedly before this, viz., that it is just

the milder and apparently harmless syphilitic infections, which are followed later on by severe syphilis of the nerves, intrudes itself also with regard to tabes, according to my observations.

The author's experiences push him more and more towards the unitarian view of syphilis. At any rate, the *absence* of most, or even of *all*, the so-called secondary manifestations of syphilis, is by no means a proof for the *non-syphilitic* nature of the previous chancre.

Only after the decision of the question in the unitarian sense, would we be entitled to state *that tabes in* 90 per cent. *of all cases is occasioned by syphilis as one of the etiological factors.*

The Analytical Study of Auscultation and Percussion, with reference to the Distinctive Characters of Pulmonary Signs.

In the Medical Section of the London Congress, Dr. AUSTIN FLINT, of New York, read a paper, the object of which was to indicate the pulmonary signs which are determinable by the analytical method of study, and the characters by which they may be readily distinguished. The auscultatory signs referable to respiration, the loud voice, and the whispered voice, were considered; and, afterward, the signs produced by percussion. The characters of the normal respiratory or vesicular murmur were brought into comparison with those of the sign known as the bronchial or tubular respiration. Under the head of bronchial respiration, a new term—broncho-vesicular respiration—was proposed to mark the different grades of solidification below the amount requisite for bronchial respiration. Cavernous respiration was shown to have characters clearly distinguishing it from bronchial respiration. Modifications of cavernous respiration, determinable by means of analysis and comparison, were distinguished as broncho-cavernous and vesiculo-cavernous respiration. A prolonged expiratory sound was stated in the paper to denote either solidification of the lung, or absence of solidification, by characters relating to pitch and quality. The existence or the absence of solidification could thus be ascertained by characters pertaining exclusively to expiration, when an inspiratory sound was wanting. The foregoing respiratory signs, referable to the loud voice, were next taken up. The distinction between simply increased vocal resonance and bronchophony was the object of analytical study. Ægophony was shown to be a modification of bronchophony, differing from the latter in an apparent distance of the resonance and an interrupted or tremulous character. Pectoriloquy, the transmission of speech or articulated words, denoted either a cavity or solidification of lung. The sounds caused by the whispered voice were considered of sufficient practical importance to form a distinct group of physical signs. The abnormal modifications of the normal bronchial whisper were as follows: (1) increased bronchial whisper; (2) whispering bronchophony; (3) cavernous whisper; (4) whispering pectoriloquy. Whispering pectoriloquy might signify either solidification of lung or a cavity. The characters associated with the pectoriloquy enabled the auscultator to decide which one of these two anatomical conditions, in individual cases, was represented by the sign. The paper concluded with the results of the analytical study of the physical signs obtained by percussion. The number of morbid signs furnished by percussion need not exceed six, namely: (1) absence of resonance, or flatness; (2) diminished resonance, or dulness; (3) increased or vesiculo-tympanitic resonance; (4) tympanitic resonance; (5) amphoric resonance; and (6) cracked-metal resonance. These were discussed in succession.

Dr. DOUGLAS POWELL (London) said it was a pity Dr. Flint did not lay down general laws, rather than refer to particular cases. Many of the sounds of prolonged expiration heard in bronchitis and emphysema were really *râles* produced

by an interruption of the current of air passing down the tubes; and often there was no such sound if it was not interrupted. With regard to bronchial and cavernous breathing, all had seen the fixed character of the chest in pneumonia, and in lungs which had caverns in them; it was impossible to explain the sounds heard over such lungs by the to-and-fro passage of air; but these sounds might occur by conduction from the glottis.

Dr. D'ESPINE (Geneva) thought that Dr. Flint's paper pointed to the uncertainty of always knowing whether we are listening to a bronchial or a vesicular sound. He had been taught in Germany that, when the sound came from the lung, the consonant V could be used with the sound produced; but, if from the bronchial tubes, the aspirate H could be produced with the sound. The binaural stethoscope was a great aid to diagnosis, as, by its means, the superficial sounds of the chest were best detected; but to the ear alone, or an ordinary single tube, the deeper sounds were given off.

Sir WILLIAM GULL (President) asked if it were possible to diagnose a cavity in the lung by any means whatever; or to distinguish always the sounds over a cavern from those over some bronchial tubes.

Dr. MAHOMED (London) said that students had great difficulty in distinguishing chest-sounds. What was wanted was a correct definition of the terms in genral use; and, if the Congress were to appoint a committee to determine the meaning of these terms, it would be a good step in the right direction. For instance, "rhonchus" and *râles* were in many text-books used synonymously; also the terms "bronchial and cavernous respiration." Again, "pectoriloquy" was limited by some to the transmission of whispered sounds, as compared to that caused by the resonance of the larynx. Numerous other examples showed that the confusion of terms was extreme.

Dr. THEODORE WILLIAMS (London) said that, before arriving at the conclusions which Dr. Mahomed desired, it would be necessary to unite in using and speaking of one code of instruments. All the first works on auscultation were written when one instrument, the simple tube, was in existence; but now there was in very general use a binaural stethoscope, manufactured of totally different material, which conveyed to the ears sounds totally different from those of the single one; and, further, the description of sounds detected by these instruments did not correspond.

Dr. FLINT, in reply, said that, as regards bronchial and cavernous respiration, Skoda said they were the same in character; but he (Dr. Flint) thought the one was distinct from the other. Bronchial respiration was high-pitched, tubular; and the expiratory sound was also high-pitched. Cavernous respiration was low in pitch, non-tubular; and the expiratory sound was still lower in pitch, and also non-tubular. He agreed with Dr. Mahomed's suggestion. Bronchophony and pectoriloquy were often confounded; and a committee would do good, if they settled the value of the terms. As regarded the stethoscope, the binaural had a great advantage over the single one; as, although the area of sounds was limited with the former, still it distinguished chest-sounds to a remarkable degree. Dr. Flint had used it for a quarter of a century, and advised its use. Although the instrument did give off a sound of its own, still the mind soon became accustomed to the sound, and finally disregarded it.

Sir W. GULL proposed, "That Professor Ewald (Berlin), Professor D'Espine (Geneva), Dr. Douglas Powell (London), Professor Austin Flint (New York), and Dr. Mahomed (London), do constitute a committee to consider, and, if possible, to fix on, some definite terms to be used in auscultation of the chest, so as to form a uniform nomenclature; and to report the result of their labours to the next Congress, wherever that may be held." This was carried unanimously.—*British Med. Journal*, Aug. 27, 1881.

Surgery.

The Healing of Wounds.

The treatment of wounds always occupies so large a share of the attention of every surgeon, that it was only meet that the several important questions in connection with it should have been freely raised at the recent Congress. The Surgical Section devoted a whole morning to the consideration of the means best calculated to secure primary union of wounds, and although there were some differences of opinion, in the main the old classical principles were reasserted. As in so many other cases, it is well to approach this subject through the study of the simplest cases. In the treatment of a simple cut of the finger, or after the operation for hare-lip, the essential principles to observe are to adjust as perfectly as possible the clean-cut surfaces, hold them in exact apposition, and keep the part at rest and free from all disturbance until union has occurred. A simple observance of these particulars is all that is necessary to obtain union by first intention, and every one of these is essential. If the surfaces are not placed in apposition, if they are not retained in contact, or are not at rest, union by first intention does not occur. Now in all this we have not had occasion to say anything about germs, or sprays, or antiseptics. We suppose no one regards the one as dangerous or the other essential in treating such simple incisions; and Professor LISTER has himself brought forward evidence to show that healthy blood-serum and blood-clot are not favourable nidus for the development of bacteria. We may advance further to large incised wounds, such as of the abdominal wall in ovariotomy, where observance of the same principles is sufficient to secure primary union. But if we go beyond this we reach cases of larger or irregular wounds, such as in an amputation, where the conditions are seriously modified. If we attempt to carry out the treatment on the same lines, we are at once confronted with the circumstance that the *exact apposition* of the wound surfaces is impossible; the edges of flaps may be brought together and carefully united, but no suturing, be it ever so skilful, is able to place every portion of wound surface in close contact with some other portion of wound surface and retain it so. One of the necessary conditions for primary union being wanting, failure results. As a consequence of this want of exact apposition, fluid accumulates in the spaces and interstices, and may so distend them as to irritate the nerves of the part and thus lead to inflammation, or may decompose and then excite inflammation by its directly irritating properties, or, being absorbed, may lead to general blood-poisoning. In either case the wound fails to unite throughout by first intention. The difficulty thus raised has presented itself in various ways to many minds, and hence has arisen the divergence in practice. Some surgeons, such as Messrs. Savory and Gamgee, make it their aim to carry out the three cardinal principles of wound treatment as far as possible in these complicated cases, and then by simple means prevent the ills to which they are exposed. They urge that such wounds should be treated in a great degree like simple wounds; that the parts—not the edges alone—should be adjusted with the greatest care, and retained in that position, and perfect rest secured, while the fluid exuded into the unavoidable spaces should be drained off and received into some kind of dressing in which its decomposition is prevented. The special means used are pressure, drainage-tubes, and an absorbent antiseptic dressing. Another school of surgeons, while not professing to neglect the principles named, are yet so impressed with the evils attending the decomposition of retained fluids, and rightly tracing such decomposition to the influence of minute organisms introduced from without, that they concentrate their attention—in some cases their

sole attention—upon the prevention of the access of these "germs" to wounds. Here, at once, two new elements are introduced. First, some agent has to be used which acts destructively upon the "germs," and, as these germs are organic, they share to some extent the properties of all organized structures, and the strongest antiseptics are injurious in their action on the human body also. A very careful adjustment of means to ends is thus required, the imperfection of which has made us familiar with constitutional disturbance, amounting even to death, from the effects of the agent employed to ward off decomposition. The second element introduced arises from the fact that the effused fluids are organizable, and if preserved from contamination, even in large quantity, can organize and so cicatrize a wound. In one particular the divergence in practice has recently became greater, for while the one school of surgeons look upon primary union of a wound as the surest safeguard against septic mischief, the other school, confident in its own power of preventing septic mischief, will forego the primary union of a wound in attaining this end. The difference between the two parties may, indeed, be roughly expressed thus: that while the one, confronted by complex conditions, proceeds as far as possible along the lines observed in the simpler, the other attacks them by entirely novel, methods. We say "roughly" advisedly, because, as was well pointed out in one of the recent debates, where primary union is achieved, sepsis is prevented by that very condition. Which of these two lines of practice will ultimately prove the more successful it would be foolish and useless to attempt to predict. At present the general statistics of the one bear comparison with those of the other, and it may be that each will have to accept a part of the other, or seek its aid in certain classes of cases.

We have, of course, been referring to so-called "Listerism," but we have purposely avoided using that name, and one reason for so doing is that it is unjust to so great a man to use his name in connection merely with a special means of dressing wounds. We consider Mr. Lister's work as far too great to be narrowed down to be a mere matter of spray and gauze. It is not a mode of dressing wounds that he has introduced, but a surgical revolution that he has accomplished. There is not a hospital in the whole civilized world that has not been affected by his teaching and labours, even if a spray, or gauze, or even carbolic acid, have never been found in its wards. He has gone far towards abolishing suppuration, and taught us all to consider it a preventable accident in the healing of an operation wound. And it is to him above all others that we owe it that septic diseases are now generally held to be avoidable, and their occurrence a serious reproach. His work, in fact, has been far greater than the perfecting the form of dressing that bears his name, and he can fairly count among his disciples many whose outward ritual differs *in toto* from his own.

It is interesting to notice the development which the antiseptic method of dressing wounds is undergoing. Carbolic acid has evidently had its day; the cause of immense good, its use has yet been attended with such inconveniences, and in some cases peril, that it has been, or shortly will be, replaced by other and safer means. The spray, which by some has been considered one of the pillars of the system, has been abandoned by many of Mr. Lister's most ardent followers, and he himself has spoken of it as likely to become unnecessary. The gauze, too, is being replaced in some hospitals by more absorbent, softer, and more elastic materials; so that Esmarch—an antiseptic surgeon whose brilliant statistics would be incredible from any less trustworthy source—dresses his cases far more after the fashion of Mr. Gamgee than that of Mr. Lister, and has shown that the transition from one to the other is neither difficult nor illogical. We cannot doubt that, amid all this development and change, surgery is advancing, and truth is being preserved; and Mr. Lister is far too wise a man to think that

finality has been attained in the so-called "Listerian" dressing. Side by side, however, with this development, another fact is prominent. Our hospitals, previously dirty, have become clean; surgeons, before too careless, are now scrupulous in their attention to cleanliness in all its details. And, as Mr. Lister himself says, it is "bits of dirt" that do the harm. Is it that his crusade has to a very large extent—would we could say entirely!—prevented these "bits of dirt" from being deposited on or in wounds, and that so previously necessary antiseptic precautions are now dispensed with in safety? Or did his earlier teachings err in considering the invisible floating particles in the air as more dangerous than they really are? Whatever may be the truth in the matter, it seems plain that the great lesson of antiseptic surgery has been widely learnt, and bids fair soon to be universally mastered. We now want to assign it its proper place in the management of wounds, as one of the elements—not the sole—to be considered by the surgeon; and it will not be surprising should the next few years witness a great simplification of its details as a juster conception of its influence and worth is attained. The danger has been that the "system" should blind some of its followers to the fact that Nature works along certain lines or according to certain principles, all of which must be understood by the successful surgeon; and surely when primary union of a wound is dispensed with in order that the "system" may be carried out, this danger has become real indeed!—*Lancet*, Sept. 3, 1881.

—

Treatment of Detachment of the Retina by Injections of Pilocarpine.

Dr. DIANOUX, of Nantes, stated at the London Congress that he had treated sixteen cases of detachment of the retina by methodical injection of nitrate of pilocarpine only, of which there were cured 6, improved 8, and unsuccessful 2. In his opinion treatment by methodical injections of pilocarpine should be employed from the beginning in all cases of detachment not symptomatic of hopeless disease. It is greatly superior to other modes of treatment. It is harmless, and in some cases no other plan is applicable. The dose should be strong at first, then moderate (salivation of at least two hours' duration). There should be a series of fifteen consecutive injections; and then a rest of eight days, etc.

Treatment should be kept up at least three months. When the result is favourable at first, the treatment should be continued till a decidedly stationary condition is reached.

The case should be kept under care and the injections resumed if there be the least evidence of a relapse.

—

The Relation between Ophthalmoscopic Conditions and Intra-Cranial Disease.

Dr. BOUCHUT, of Paris, in some remarks before the London Congress, held that all the important diseases of the brain and cord, as well as the serious diathetic diseases, may be recognized by ophthalmoscopic examination, and he applies the term cerebroscopy to this use of the method.

Thus, congestion and swelling of the optic nerve indicate congestion of brain, meningitis, compression of brain, or commencing spinal disease. Œdema of disk and neighbouring retina shows œdema of meninges and obstruction to circulation in the sinuses and meningeal veins, in tubercular meningitis, in acute and chronic hydrocephalus, in cerebral hemorrhage, in certain cerebral tumours accompanied by encephalitis, etc. Complete anæmia of the nerve and retina shows arrest of cardiac and cerebral circulation. Death is thus easily diagnosticated by the ophthalmoscope. Retinal varices and thromboses indicate thrombosis of the sinuses and meningeal veins. Miliary aneurisms of the retinal arteries show miliary aneurisms of the brain.

In fevers and diseases of the nervous system retinal hemorrhages indicate either compression of the brain by a copious effusion, the hemorrhagic diathesis, cardiac obstruction to the cerebral circulation, or changes in the cerebral and retinal vessels caused by chronic albuminuria, glycosuria, syphilis, and leucæmia. Miliary tubercles of the retina and choroid show tuberculosis of the brain or meninges. Lastly, in nervous diseases, atrophy of the disk or sclerosis of the optic nerve always indicates a disseminated sclerosis of the brain or of the anterior columns of the cord.

—

On the Relations between Adenoma, Sarcoma, and Carcinoma of the Mammary Gland in the Female; their Diagnosis in the Earlier Stages of Disease, and the Results of their Treatment by Operations.

Dr. SAMUEL W. GROSS, of Philadelphia, in a paper read at the London Congress, presented the results which he has obtained from an elaborate study of this subject, and offered the following propositions:—

1. That from a genetic stand-point there is a distant connection between adenoma and carcinoma, since they both originate from the glandular constituents of the mamma. In the former neoplasm, however, there is a numerical increase of the lacteal glands; in the latter, there is merely a multiplication of the epithelial cells, the descendants of which extend into the lymphatic vessels and the perivascular sheaths of the bloodvessels. From a clinical standpoint, adenoma is a benign tumour, and carcinoma is a malignant growth.

2. That sarcoma has neither a genetic nor a structural affinity with adenoma or carcinoma, but that it resembles the latter in its malignant attributes.

3. That, in view of the recurring tendency of adenoma after simple enucleation, the entire breast should be extirpated with it.

4. That surgical intervention in sarcoma and carcinoma not only retards the progress of the disease by preventing local dissemination and the development of visceral tumours, but it also not infrequently results in permanent recovery.

5. That local reproductions in sarcoma and carcinoma do not militate against a final cure, provided they are freely excised as soon as they appear.

6. That lymphatic evolvement does not forbid operations in carcinoma, since infected glands were removed in nearly one-third of the examples of permanent cure.

7. That the subjects of sarcoma and carcinoma are, almost without exception, safe from local and general reproduction if three years have elapsed since the last operation.

8. That all sarcomata and carcinomata of the mammary gland, if there are no evidences of metastatic tumours, and if thorough removal is practicable, should be dealt with as early as possible by amputating the entire breast and its integuments, and dissecting off the subjacent fascia. In carcinoma, moreover, the axilla should be opened with a view to its exploration and the removal of any glands which were not palpable prior to interference.

—

Etiology of Aural Exostoses and their Removal by a New Operation.

Dr. JAMES PATTERSON CASSELLS, of Glasgow, read a paper on this subject at the London Congress, of which the following are the conclusions:—

The osseous tumours of the external meatus are of two kinds, the one, named hyperostosis, being a hyperplasm; the other, exostosis, being a new growth. These differ from each other in origin, site, shape, structure, and number.

Hyperostosis is never seen till the osseous meatus is completely ossified; exostosis appears before the complete ossification of the meatus. Exostosis is found

arising from a point near the junction of the osseous canal with its cartilaginous portion; hyperostosis is seen only in the inner, or osseous end of the external auditory canal. Hyperostosis is always conical in shape, never pedunculated; in exostosis, on the other hand, there is always a pedicle, and its shape varies. Hyperostosis is of ivory hardness; exostosis before complete ossification has taken place in the tumour, can be pierced to a varying depth. Hyperostosis is not movable on pressure; exostosis is slightly movable, even when complete ossification has taken place. Hyperostosis is often seen without any other disease of the ear, and if an ear disease exists, there is no causative relation between them; they exist altogether independently, and apart from each other. Exostosis is nearly always complicated with another affection of the ear, past or present. Hyperostosis, therefore, may exist in the meatus with normal hearing. Exostosis, on the other hand, is almost always attended by a defect in the hearing. The deafness which accompanies hyperostosis, in the absence of any other disease of the ear, is due to the size of the growth, and is mostly mechanical, or it is due to the presence of *débris* between or behind the tumours. In exostosis the defect in the hearing may also be mechanical; this defect, however, is generally due to ear disease, either past or present.

The operation for the removal of hyperostosis is only justifiable, when its mechanical presence has been ascertained to be the sole cause of the deafness, or when a coincident ear discharge exists, the escape of which may be hindered, or altogether arrested by the presence of the tumour. The commonest cause of deafness in hyperostosis is the presence of *débris* around the tumours, either cerumen, epidermic masses, or other matters, or to mechanical irritation and inflammation of the tissues that cover them. The hearing is mostly restored on the removal of the *débris* or inflammation. The operation for the removal of hyperostosis is best effected by a mechanical drill, such as dentists use; this is the safest method of removal.

For the operation of the removal of an exostosis a gouge is the best instrument, because the tumour can be removed at one operation, whereas a hyperostosis usually demands several operations, as well as separate sittings, for its complete removal, when this is possible. There may be several hyperostoses in an ear, but hardly ever more than one exostosis. Both classes of tumours may exist together in the same ear.

—

Laparotomy and Cystorrhaphy in Cases of Perforating Wound of the Bladder.

Dr. E. VINCENT, of Lyons, presented at the London Congress the results of a new series of experiments performed upon rabbits, and the following conclusions which he deduced therefrom:—

I.—1. The contact of urine with the peritoneum is not such a fatal accident as is usually supposed.

2. Suture of the bladder by interrupted metallic stitches, the serous surfaces being brought into contact, and the stitches left in the abdomen, may be practised with almost a certainty of success.

3. Whatever the cause of rupture, the animal can almost invariably be saved if the vesical suture be practised immediately or within a very short time, even if grave complications be present.

4. The animal may be saved even if a considerable time be allowed to elapse after the injury

5. When the operation was delayed longer than sixteen hours, some animals died from urinary intoxication without true peritonitis; others survived owing to a spontaneous closure of the opening in the bladder.

6. The spontaneous closure is exceptional, and, therefore, laparotomy and cystorrhaphy should be at once practised.

II.—Taking into consideration these and previous experiments, and the result of a case in which a large piece of the bladder was excised accidentally during an ovariotomy, the author would formulate the following propositions as applicable to the human subject:—

7. Considering the almost invariable mortality which follows wounds of the bladder, however produced, laparotomy and crystorrhaphy should be resorted to immediately. The chance of success diminishes in proportion to the length of time that has elapsed since the accident.

8. As the employment of antiseptic means has removed the danger of operations involving the peritoneum, ought we not to prefer suprapubic lithotomy to any of the perineal methods, retaining only two operations for stone; lithority, if it be friable and small; suprapubic lithotomy, if it be very large or hard?

—

Pathology and Treatment of Genu Valgum.

Mr. BERNARD E. BRODHURST was the author of a paper on this subject read at the London Congress, of which the following is a full abstract:—

Genu valgum is regarded as a constitutional rather than as a local defect; and it is shown to be accompanied for the most part by a relaxed condition of the ligamentous system in general, and to be preceded by flat-foot. Especially the ligaments on the inner side of the ankle, and those in the sole of the foot, having yielded, the arch of the foot becomes flattened, and the foot itself everted; the inner malleolus projects inwards and is lowered towards the ground, and the shaft of the tibia is inclined outwards.

Thus the weight of the body is thrown unduly to the inner side of the limb, and is borne rather on the inner margin of the foot than on the entire breadth of the sole of the foot.

Secondly, the long axis of the femur becomes inclined inwards, the inner condyle protrudes, and the internal lateral ligament yields to the superincumbent weight, and the weight of the body being no longer borne in a vertical line and transmitted through the long axis of the femur and the tibia to the arch of the foot, is thrown to the inner side of the knee and of the foot. These, then, being the relative positions of the femur and the tibia, the former inclined inwards and the latter outwards, the condyles of the femur necessarily assume an oblique position from without inwards.

In the normal condition of the bone, there is usually some difference in the length of the condyles: in a rickety bone the inner may be one inch longer than the outer condyle; in the rickety bone the inner condyle is nipple-shaped, and the outer is undeveloped, or almost absent; so that the superincumbent weight could never have been borne on the foot, but it was probably borne on the knee. The length of the inner condyle varies according to the healthy development of the bone. The difference in length may be less than 1-10th of an inch, or it may be in an ordinarily healthy bone as much as half an inch.

In its commencement genu valgum is only apparent in the erect position, and it ceases in the horizontal position, just as is observed in scoliosis and in flat-foot; in an early stage of development these disappear in the horizontal position.

After some time, knock-knee becomes permanent. Even now, however, splints firmly supporting the knee, together with the horizontal position, are sufficient to remove this deformity.

As deformity increases, the biceps femoris becomes tense, and the ilio-tibial band and the external lateral ligament are rendered rigid. Then the right line of the limb being destroyed, the question arises how is it to be restored, so that

it shall pass through the long axis of the femur and of the tibia, and impinge on the arch of the foot?

Various operations have been proposed to restore the straight line of the limb, such as forcible straightening, osteotomy, and tenotomy.

Tenotomy, however, or that operation known as Guérin's, is sufficient; without either force or osteotomy, to remove the most severe forms of genu valgum.

Perforating Ulcer of the Foot as connected with Progressive Locomotor Ataxy.

Prof. BENJ. BALL, of the Paris Faculty, and Dr. THIBIERGE, presented the following conclusions in a joint paper on this subject read before the London International Medical Congress:—

1. Perforating ulcer of the foot is, in such cases, the consequence of the spinal disease, as in the "joint disease," which has been brought before the medical public by Charcot and myself.

2. The local disease is more especially connected with certain symptoms of locomotor ataxy, such as shooting pains, absence of tendon reflex, and other trophical lesions.

3. The perforating ulcer may be cured while the symptoms of locomotor ataxy follow their progressive course.

Midwifery and Gynæcology.

Parallel between Embryotomy and the Cæsarean Section.

Dr. G. EUSTACHE, of Lille, in a paper read at the London Congress, presented the following conclusions, which he believed should be the future rules of practice:—

Considering, on the one hand (1), the recent results of ovariotomy, and of all other abdominal sections; (2), the improvement in the prognosis of all surgical inquiries under antiseptic treatment; (3), the success of Porro's operation; (4), the immensely favourable results both to mother and child after the Cæsarean section, which have been published during recent years.

And considering, on the other hand, that embryotomy, while it always sacrifices the child, exposes the mother to as grave dangers as the Cæsarean section; that it is inapplicable in many cases of deformed pelvis, *e.g.*, when the conjugate is 5 centimetres and under.

I conclude:—

1. When the child is living at the beginning of labour, and when the pelvic strait is under 78 mm.—the extreme limit for the application of the forceps—the Cæsarean operation should be performed early, that is to say, as soon as labour has really set in, and with antiseptic precautions.

2. If the child is dead, and the superior strait measure 5 centimetres, recourse should be had to embryotomy. Below 5 centimetres the Cæsarean section becomes an operation of necessity.

To sum up, the Cæsarean section should be the method of election, embryotomy that of exception.

The Curability of Uterine Displacements.

Dr. PAUL F. MUNDÉ, of New York, finding that the text-books either entirely omit all mention of the possibility of permanently curing displacements of the uterus by any of the methods in use, or give but vague statements on the subject,

and impressed with the importance of having some positive conclusions on this matter, both for the sake of the patient and the satisfaction of the physician, in a paper presented to the London Congress has analyzed the numerous cases of displacements which have come under his care (895), and arrives at the following conclusions:—

1. Displacements of the uterus are permanently curable in the large majority of cases only when recent, or when a complete tissue metamorphosis, as occurs during pregnancy and after parturition, takes place.

2. Chronic cases (of more than a year's standing) are but rarely curable permanently, except occasionally under the last-named circumstances. Apparent cures reported by some authors and witnessed by many physicians, soon show themselves to have been but temporary.

3. Pessaries form unquestionably the most practical, rational, and (temporarily) the most efficient means of treating uterine displacements. Cures are but rarely accomplished by them.

4. Medicated, chiefly astringent, tampons, intelligently applied every day by the physician, give the best chances for permanent cure. This is particularly true of prolapsus, but holds good for all forms.

5. Electricity locally applied deserves more extended application.

6. All methods should be persevered in for months and years before success is to be expected.

—

Removal of both Ovaries for the Cure of Insanity.

Dr. T. B. WILKERSON, of Youngs Cross-roads, Granville, N. C., reports in the *North Carolina Medical Journal*, June, 1881, the case of a young woman 19 years of age, in which he successfully extirpated both ovaries for insanity with strong erotic tendencies of two years' duration. At the end of three weeks she recovered from the operation, and there was a gradual improvement in the mental condition, and three months after the operation sanity was perfectly restored. Nine months after the operation she is reported as being "gay, lively, cheeks ruddy, and in the full enjoyment of a vigorous mental and physical health."

Hygiene.

Influence of Milk in Spreading Zymotic Disease.

At the London Congress Mr. ERNEST HART, the talented editor of the *British Medical Journal*, submitted an abstract, giving in a tabular form particulars of 71 recent epidemics due to infected milk, that have been recognized and made the subject of detailed observations in Great Britain, 67 of them since the Marylebone milk typhoid epidemic, traced and reported by Dr. Murchison and the author, in 1873. The particulars of the epidemics are given in the abstract under the following headings:—

1. Date of outbreak; 2. Locality; 3. Reporter; 4. Total number of cases; 5. Deaths; 6. Number of cases amongst drinkers of infected milk; 7. Percentage to total cases (col. 6 to col. 4); 8. Number of families supplied by milkmen; 9. Number of such families invaded; 10. Percentage (col. 9 to col. 8); 11. Sanitary circumstances of farm or dairy from which milk was derived; 12. Exciting cause of outbreak; 13. Circumstances implicating milk; 14. Facts showing special incidents of the disease; 15. References to sources of information.

The three diseases which have as yet been recognized as capable of being spread by milk are typhoid fever, scarlatina, and diphtheria. There is nothing

in the analogy of epidemics to limit the list permanently to these; and already there are indications of other cognate diseases being spread by the same agency. The number of epidemics of typhoid fever recorded in the abstract as due to milk is fifty, of scarlatina fourteen, and of diphtheria seven. The total number of cases traced to the drinking of infected milk occurring during the epidemics may be reckoned in round numbers as 3500 of typhoid fever, 800 of scarlatina, and 500 of diphtheria. As regards typhoid fever, the most common way in which the poison has been observed in these epidemics to reach the milk is by the soakage of the specific matter of typhoid excrements into the well-water used for washing the milk cans and for other dairy purposes, and often, it is to be feared, for the dilution of the milk itself—for which, in official reports, "washing the milk cans" has become a convenient euphemism, advisedly employed to avoid raising unpleasant questions.

In twenty-two of the fifty epidemics of typhoid fever recorded this is distinctly stated by the reporters to be the case, and in other cases it was more or less probable.

When a dairy is unwholesomely or carelessly kept, there is obviously a great variety of ways in which the poison may reach the milk. (Numerous instances of this kind are given.)

Scarlatina being almost invariably spread by contagion and by the inhalation of the bran-like dust which is thrown off from the body during the disease, we should expect in epidemics of milk-scarlatina to receive evidence of this dust having access to the milk; and in the majority of recorded epidemics it was found that persons employed about the dairy operations were in attendance at the same time on persons sick of scarlatina.

In none of the seven recognized outbreaks of *diphtheria* due to milk, has it yet been possible to trace the exciting cause of the outbreak, though as to the disease being spread by milk there could be no doubt whatever. It has indeed been suggested whether a disease of the udder of the cow, called "garget," may not so affect the secretion of milk as to give rise to diphtheria in the human subject. So far, this notion is a mere conjecture unsupported by fact.

The great majority of the cases give statistical as well as experimental support to the conclusion that the responsibility of the epidemic lay with the milk.

It is upon the largest drinkers of the milk (those, namely, who, consuming the greatest quantities, have a correspondingly greater chance of imbibing disease germs), that the incidence of the disease chiefly falls.

Thus young children (ordinarily little liable to attacks of typhoid) who are accustomed to drink milk largely in the raw state, domestic servants, who, after children, drink the most raw milk, and large milk drinkers of every rank and station, furnish by far the largest quota of cases in each epidemic.

People, too, who drink exceptionally of the implicated milk are attacked, although the milk taken at their own houses is derived from other sources.

The houses invaded during the epidemics are found to be commonly of the better class and in healthy situations. The poor, who take very little milk, and that only in tea or coffee, commonly escape the disease.

The striking fashion in which the disease "picks out" the streets supplied by the implicated dairy, and the houses in those streets receiving the milk, is noteworthy. People in adjacent houses, and who drink milk supplied by different retailers, escape; and when supplies from two sources enter the same house, the disease only attacks those drinking that from the infected source. The contemporaneous invasion of so many households at once can only be explained on the hypothesis of a common cause acting on a particular set of persons, and on no others

MEDICAL NEWS.

The Case of President Garfield.

The publication in the current number of the *American Journal of the Medical Sciences* of the official report of the autopsy upon the body of President Garfield will, we trust, while satisfying the legitimate curiosity of the profession and of the laity, at the same time effectually and permanently quiet the unfriendly criticism of the surgical treatment of the case, in which part of the daily press has so freely indulged, and from which, we regret to observe, some medical journals without full knowledge of the case have not thought proper to abstain. The discoveries of the autopsy, taken in conjunction with what is known of the clinical history, will at once make apparent to the profession the good common sense, admirable conservatism, and sound surgical judgment which have characterized the management of the case from first to last, and, although the non-medical mind may be slower to comprehend the questions at issue, it will not be long before the same conviction forces itself upon the people at large.

We know now beyond the possibility of doubt that no human skill could have averted the fatal result, but we find moreover that, even in the searching light of the careful and thorough post-mortem examination, it is difficult, if not impossible, to suggest any modification of the treatment even in minor points, which would have made it better adapted to the exigencies of the case.

Directly after the shooting, the symptoms of impending collapse, so severe as to threaten immediate dissolution, and possibly, in the absence of hemorrhage, depending largely upon spinal concussion and mental shock, received, as was proper, the greatest attention.

Later in the day, after reaction had been established, a cautious examination with a probe and with the finger disclosed the fact that the eleventh rib had been struck and broken, and that the ball had passed onward into the abdominal cavity. In accordance with one of the best-established rules of surgery, further exploration was desisted from, and two days later, at the time of the first consultation, the same praiseworthy conservatism was observed in spite of the senseless clamour for the extraction of the ball which was already being raised, and which, to their shame, be it said, was aided and encouraged by a few prominent members of the profession who had possessed neither the details nor a personal knowledge of the case. Although, at that time, the surgeons were governed by general principles, and were necessarily ignorant of the course and situation of the

ball, the wisdom of their inactivity has been made clear by the disclosures of the autopsy, and we can all recognize now that an operation for extraction would have been not only fruitless, but almost certainly fatal, while, on the other hand, it is shown that the ball itself, after effecting its lodgment, had ceased to be a factor in the production of disease. We know also, that, as it had passed through the fibres of the psoas muscle, which, running longitudinally by the side of the spine, had closed over it, persistent probing would only have been productive of increased laceration of the parts with no possibility of the discovery of the track of the ball.

It seems not improper to say in this connection that weeks ago, when the daily press was filled with fictitious accounts of the exact situation of the ball, and of certain imaginary movements which it had made, Dr. Agnew, who, doubtless, in this, as in other matters, represented accurately the sentiment of the surgical staff, assured us that he did not know the position of the ball, and knew of no safe means of determining it.

The vomiting immediately after the accident, and the temporary retention of urine were common symptoms of shock, and received all the attention they required; so, too, the pains in the feet and ankles and the scrotal hyperæsthesia—both possible results of nerve-injury or of concussion of the spine—called for no special treatment, and subsided, together with the abdominal tympany, in from one to two weeks. At no time was there any loss of muscular power. The rigors which occurred about the end of July were immediately associated, in the first instance, with the formation of a small abscess under the erector spinæ muscles, possibly caused by the irritation of fragments of the broken rib, and next, with the obstruction of the outlet from this pus-cavity by one of these fragments. A free incision in the one case, and removal of the spicula of bone in the second, caused an immediate cessation of the chills, followed by subsidence of the temperature. It seems probable that about this time the blood received its first septic impression; but this is not to be wondered at when we recall the fact that suppuration occurring in this region is rarely circumscribed, the pus, owing to the scanty amount of connective tissue and to the presence of loose masses of fat, finding its way freely through the surrounding parts, and thus affording the best possible condition for decomposition and for the absorption of poisonous matters. When, too, we remember the laceration of the cancellated structure of the first lumbar vertebra, it seems rather remarkable that these symptoms did not make their appearance earlier, and the injustice of attributing them to improper or insufficient treatment becomes evident.

The discovery of a point of induration in the right iliac fossa, and the fact that a small flexible catheter could be carried downward from the wound in that direction for several inches, led very naturally to the harmless belief that this was probably the original track of the ball; but, while the au-

topsy shows that this was not the case, it also develops the fact that the wound proper was thoroughly drained through this channel, and that the operation of August 8th, which, by an opening below the twelfth rib and directly through the quadratus lumborum muscle, effectually drained the space between that muscle and the peritoneum, and, indeed, the whole iliac and lumbar regions, also aided in carrying away the products of suppuration from the neighbourhood of the wounded vertebra.

The drainage of the long, narrow passage into the iliac fossa by a counter-opening at its lower extremity, which it has been asserted was an indication not met by the surgeons, would have necessitated an abdominal section, displacement of the viscera, and division of the posterior layer of the peritoneum, and would have resulted in absolutely no benefit, as in the recumbent position the pus would have continued to gravitate toward the opening in the lumbar region, as it did throughout the entire case.

The fact that drainage was thorough and complete, and that no portion of the unfavourable symptoms was due to neglect in this respect, is finally and fully established by the circumstance that no accumulations of pus were found at the autopsy, either along the track of the ball or in the passage caused by the burrowing of the pus. There was no time previous to the first operation at which the accumulated pus did not pass out of the original wound, but its exit was favoured by gravitation after the two operations which brought the external openings on a lower level, and enabled them not only to drain completely the iliac and lumbar regions, but also to carry away any discharge that may have come from the fractured vertebra.

Throughout the whole treatment antisepsis was employed to the fullest possible extent, although a more unfavourable case in which to obtain its peculiar benefits could hardly be imagined.

The irritable stomach, a relic of old dyspeptic troubles, the parotitis, a not uncommon accompaniment of exhausting fevers, the bronchitis and broncho-pneumonia, partly the results of recumbency and partly of the septic state of the blood, were the subsequent complications through which the President was being so skilfully, and we may say, successfully carried, when the ulceration of the splenic artery, a slowly developing result of inflammation extending from the contiguous track of the ball, terminated the case; the rigors preceding death being doubtless due to the successive hemorrhages which are indicated by the lamination of the blood-clot found in the peritoneal cavity. The edges of the ulceration in the splenic artery were adherent to the posterior surface of the peritoneum. It will be seen that no metastatic abscesses were discovered, the only accumulations of pus which were found being a cavity on the under surface of the liver which may have been a result of contusion by the broken rib at the time of the injury, and at any rate did not communicate with the wound, and another,

one-third of an inch in diameter, just beneath the capsule of the left kidney. With the exception of the moderate broncho-pneumonia the viscera were free from all acute pathological changes.

From this general consideration of the history of the case, viewed in the light thrown upon it by the details of the autopsy, we may safely conclude:—

1st. That the treatment at the time of the reception of the injury, and immediately subsequent to it, was that rendered proper by the condition of collapse which then existed.

2d. That on reaction taking place, a sufficiently thorough and careful examination was made with the finger and the probe.

3d. That when the consulting surgeons were called in, and found that this had been done, they very properly, and in accordance with well-established and universally recognized rules of surgery, refrained from repeating that examination.

4th. That even if these rules had been disregarded, and such examination had been made, it would have determined nothing of practical importance as regards the subsequent treatment.

5th. That wherever pus accumulations had taken place, they were properly opened by free incisions made at the most dependent portions.

6th. That these incisions drained not only the course of the abscess, but communicated freely with that portion of the spine which had been penetrated, and, therefore, with the track of the ball, and the completeness of the drainage is shown by the absence of pus accumulations either in the locality traversed by the ball or in the iliac or lumbar regions.

7th. That the damage done to the cancellated tissue of the lumbar vertebra was sufficient in itself to explain the septic state of the system, which in time, and independent of the ball, which proves to have become harmless, would have destroyed the life of the patient.

If it be thought that these conclusions need to be substantiated by a more detailed acquaintance with the surgical history of the case, it may be said that such a history giving minutely all the particulars of symptoms and treatment is now in process of rapid preparation, and in our opinion will serve to confirm and strengthen the above assertions.

Of the sympathy of the nation and of the civilized world with the distinguished victim, of the universal respect and affection called forth by his quiet, patient endurance of his sufferings, of the admiration excited by the persistent, almost heroic, struggle which he sustained against overwhelming odds, of his watchful and tender nursing, of the thoughtfulness which anticipated every want and of the ingenuity which devised new appliances for his comfort or his transportation, enough has been written in well-deserved commendation.

But for the men who took the crushing responsibility of his case, who spared neither time nor labour nor health in its conduct, who remained

prudent and far-seeing and self-reliant under an electric light of criticism such as has been directed upon no other physicians in the history of the world, and who have in our opinion reflected credit upon the profession and upheld the reputation of American surgery, there has been written scarcely a word of praise, but oftentimes columns of unmerited censure.

—

International Medical Congress, London, 1881.

The International Medical Congress which has just adjourned at London, was the most notable medical gathering which has ever assembled in any part of the world. The Congress was honoured by being held under the patronage of Her Majesty the Queen, and of His Royal Highness the Prince of Wales. Its membership was alike international, and representative in character; and in the magnitude of the Congress, in the amount of work it accomplished, and in the attractions which it offered to those who attended it, it surpassed all its predecessors. Official representatives were sent by the governments of the United States, France, Germany, Russia, Italy, Denmark, Norway, Sweden, and by Roumania. The Prince of Wales, and the Crown Prince of Russia showed their interest in the Congress by being present at the opening meeting, and by subsequently on the same day taking luncheon with Sir James Paget, dining with Sir William Gull, and by being present at the conversazione at the South Kensington Museum in order to meet the chief notabilities of the profession who had assembled from all parts of the world to attend the Congress. The Empress of Germany graciously expressed her personal interest in the meeting by deputing Prof. Küster, Principal Surgeon of the Augusta Hospital, to attend as her special representative.

Of the scientific work done in the Sections we can only here say that the large number of papers read were, as a rule, markedly valuable contributions to our science, and the summaries of the more important will be found in our *Monthly Abstract*, and in the current number of the *American Journal of the Medical Sciences*. Some conception of the number and extent of these communications may be formed from the fact that the official volume of abstracts printed in English, French, and German, covers over 700 closely printed royal octavo pages, and contains 325 communications, extending over the entire range of medicine and surgery. The devotion of the members to the serious work for which they had assembled was most marked, and the general sessions and sectional meetings were always largely attended, and the discussions were as full and as interesting as time would permit.

Of the addresses that were made in the general sessions that of Dr. Billings, of Washington, was received with marked favour, and the sallies of wit with which it sparkled elicited cordial applause from the large audience whose attention was closely held during its entire delivery. This

able address we have laid before our readers in full, as well as that of Prof. Volkmann, who is one of the most prominent advocates of antiseptic surgery in Germany, and that of Prof. Pasteur, of Paris, which, from a scientific standpoint, is the most valuable of all, dealing, as it does, with new and original investigations, the importance of which can be scarcely over-estimated.

The social entertainments given to the Congress as a whole, or to select parties of its members, were so numerous and brilliant as to constitute a marked feature of the meeting. Indeed such a spontaneous outburst of generous hospitality as was daily met with, we believe is without parallel in the history of any scientific or popular Congress. The magnificent hospitality of the corporation of the City of London was shown in the sumptuous conversazione at the Guildhall; and the Lord Mayor of London officially entertained at dinner at the Mansion House as many members of the Congress as the Egyptian Hall would hold. Among the many notable private entertainments it is impossible not to refer to the brilliant dinner at Willis's Rooms, given by Sir William Gull, to a select number of guests invited to meet the Prince of Wales. Among the distinguished company who were not members of the profession, besides the Prince of Wales, were observed the Crown Prince of Germany, Prince Henry of Germany, Cardinal Manning, the Archbishop of York, the Bishop of London, and the President of the Royal Society. Of the members of the Congress from America there were present Drs. Billings, Solis Cohen, Austin Flint, Minis Hays, T. M. Lefferts, and D. W. Yandell.

Sir James Paget fulfilled the duties of the Presidency of the Congress with a dignity, zeal, discretion, and grace which won for him universal praise. To the unswerving energy, and quiet courtesy of the Hon. Secretary-General, Mr. William Mac Cormac, much of the superb success of the Congress is unquestionably due, and we are happy to learn that in recognition of the value of his services in promoting the Congress the Queen has signified her intention of conferring upon him the honour of knighthood.

At a meeting of the members of the Congress from the United States, held at the close of the Congress, the following resolution was passed:—

Resolved, That we highly appreciate the privilege we have enjoyed of attending this Congress, which has been, in every sense, a great success. That we offer our thanks to the officers of the Congress for the manner in which they have organized and conducted its meetings, and also to the corporations, societies, and individuals of whose unbounded hospitalities we have had such ample experience; and that we shall always preserve the most pleasant and grateful memories of the uniform courtesy and kindness which we have received, and which will strengthen the ties of friendship which exist between the United States and the mother country.

American Dermatological Association.

The fifth annual meeting of this Association was held at the Ocean House, Newport, R. I., Aug. 30th, 31st, and Sept. 1st. The proceedings opened with an able and scholarly address by the president, Dr. James Nevins Hyde, of Chicago, on *the Relations of Dermatology to Periodical Medical Literature.* A comparison of the articles published during the last few years with those of an earlier date showed a very marked improvement. Allusion was made to the importance of correct diagnosis, and some of the diseases were referred to where mistakes are frequently made. Some of the popular errors in etiology and pathology were also considered, and the injudicious use of well-known and powerful remedies, as mercury, arsenic, and iodide of potassium, strongly denounced. "He who would specially devote himself to the investigation of the diseases of the skin requires fully as much as his fellows the amplest preparation in a finished medical education and experience, and when at last ready for his work he will discover, if he has not done so before, that he needs to be a physician in the highest sense of the term. There is no organ of the body, in health or in disease, which it may not become his duty to explore and investigate." Appended to the address, the reading of which was listened to by the members of the association with the deepest interest, was a general alphabetical index, by authors and subjects, of all original communications which have appeared in the several dermatological journals.

The first paper read was one by Dr. Charles Heitzmann, of New York, on *The Minute Anatomy of the Hair*, the ground being taken that the anatomy of this structure had heretofore been incorrectly stated by authors. Dr. James C. White, of Boston, next read a paper on the *Limitations of Internal Therapy in Skin Diseases*, referring to the differences of opinion regarding the value of internal remedies among dermatologists of equal experience, and stating that in his opinion but few diseases of the skin were under the direct control of internal medication and in any uniform or marked degree. We would encourage experimental studies, empirical or philosophical, but thought that a frank confession of our present inabilities was an essential step towards real advance. This article was followed by one by Dr. Arthur Van Harlingen, of Philadelphia, describing an interesting case of *Lymphangioma cutis Multiplex.*

The next paper was one by Dr. Louis A. Duhring, of Philadelphia, on *The Small Pustular Scrofuloderm*, the disease being undescribed and rare, and characterized by small, disseminate, chronic, pustules with a hard base of a cold violaceous tint, the eruption resembling the small pustular syphiloderm.

The second day's morning session was devoted to an interesting series of articles on leprosy, and to the valuable report of the Committee on Statistics presented by the Chairman, Dr. James C. White. The first paper was on a *Case of Tubercular Leprosy*, occurring in a native of Maryland, who had never been beyond the limits of the State, and who was of healthy parentage, by Dr. I. Edmondson Atkinson, of Baltimore. Dr. Hyde, of Chicago, presented a case of acute *Tubercular Leprosy*, and read a paper by Dr. H. D. Schmidt, of New Orleans, *On the Pathology of Leprosy.* The day's proceedings were concluded by a paper by Dr. Edward Wigglesworth, of Boston, on *Buccal Ulcerations of Constitutional Origin*, the difficulties of diagnosis between lupous, tubercular, syphilitic, and cancerous disease being dwelt upon.

On the third day Dr. Heitzmann, of New York, contributed papers on *Clinical Experience in the Use of the Solution of Oxysulphuret of Calcium*, and on the use of a *Kido-Galvano-Cautery for Depilation*, his results justifying the highest claims made for the operation.

The committee on the microscopic examination of a specimen of ainhum, presented at a former meeting, reported through its chairman, Dr. Heitzmann, that the appearances presented no pathological changes to account for the result, which can only be explained by the supposition that a system of self-mutilation is practised by the negroes.

The officers elected for the ensuing year were as follows:—

President, Dr. James Nevins Hyde, of Chicago; Vice-Presidents, Drs. George H. Fox, of New York, and W. A. Hardaway, of St. Louis; Secretary, Dr. Arthur Van Harlingen, of Philadelphia; Treasurer, Dr. I. E. Atkinson, of Baltimore.

—

Tribute to the Memory of the late Dr. Otis at the London Congress.—During a discussion in the Section of Military Surgery and Medicine, on the transport of sick and wounded in the field, Dr. Gori (of Amsterdam) made reference to the death of Dr. Otis, which drew forth the following remarks from the President, Surgeon-General Longmore:—

"This seems to be a very fitting occasion, representatives as we are of the science and practice of military surgery in all countries, for us to express our profound regret at Surgeon Otis having been taken away from among us before he was able to complete the greatest of all his many valuable professional works, as he had hoped to do; and it seems also to be a fitting opportunity to convey to Surgeon-General Barnes, and, through him, to all the medical officers of the United States Army, our heartfelt sympathy with them on the great loss their medical service in particular, and at the same time military surgical science in all parts of the world, has sustained in the death of their great colleague. I say these few words in the presence of an eminent friend and fellow-labourer of Dr. Otis—Dr. Billings, who occupies an important part in the Surgeon-General's Office at Washington—and I beg to propose to the meeting that Dr. Billings be asked kindly to allow himself to be made the medium of communicating this, I may truly say, international expression of feeling—for I see plainly you all share with me in sentiments I have tried to express—to the distinguished chief at the head of the Department, and to his colleagues, on his return to Washington."

Dr. Billings, in reply, said: "In behalf of the Medical Department of the United States Army, of the Surgeon-General, and of the colleagues and friends of Dr. Otis, I desire to return thanks for, and to express the highest appreciation of, the eloquent tribute which Surgeon-General Longmore has paid to the memory of Dr. Otis. I shall not attempt to add to the eulogy which Surgeon-General Longmore has pronounced upon my friend and colleague; I can only say that I find I want words to express the emotion with which I have listened to it, and that I shall convey the message with which he has charged me, to the best of my ability. You will all, I am sure, be glad to know that before his death Dr. Otis had completed so much of the Surgical History of the War, upon which he was engaged, as relates to wounds of the extremities. There remains yet to be completed the account of the complications of wounds, such as gangrene, tetanus, septicæmia, etc. Another surgeon of the Army will be assigned to complete this history, and you can hardly conceive how difficult he will find it to prepare a report which will be the continuation of, and be constantly compared with, the work of Dr. Otis."—*Med. Times and Gaz.*, Aug. 13, 1881.

—

Health of New York.—The average mortality for August has been considerably smaller than that for July. During the latter month 4378 deaths occurred, while only about 3000 were reported for August. In the week ending Aug. 6, there were 839 deaths, and in that closing Aug. 13, 849. For the weeks ending

Aug. 20th and 27th, the numbers were respectively 682 and 679. This decrease in the death-rate may in part be attributed to the low average temperature which prevailed during the month, whereby the infant mortality was materially reduced, and to the indefatigable efforts of the tenement-house medical corps appointed by the Health Board. The special physicians of the corps completed their labours at the middle of the month, after a service of five weeks' duration.

The progressive abatement of typhus fever manifested throughout the month was the source of great rejoicing among all classes of society. In the 21st week of the fever's prevalence (ending Aug. 6), there were only 2 new cases; in the 22d week, 12; in the 23d week, 4 cases; in the 24th and last week (ending Aug. 27), only 1 case. 19 new cases were, therefore, reported against 124 in May, 101 in June, and 74 in July. In the last four numbers of the MEDICAL NEWS AND ABSTRACT, the reader will find a numerical history of the endemic, and will see that the entire number of cases reported during its course was 527. During the weeks ending Sept. 3d and 10th no cases were discovered, and the disease is, therefore, regarded as arrested. The last case of typhus was discharged from the Riverside Hospital ten days since. All the contagious diseases have decreased during August. 75 cases of smallpox were reported against 99 in July, and, on Sept. 7, only 12 cases of that disease remained at the Riverside Hospital. The number of scarlatina cases fell from 575 in July to 320 in August; diphtheria from 521 to 355; and rubeola from 231 to 96. The most intense heat of the season prevailed on Sept. 6, 7, 8, and 9. On the 6th inst., the thermometer reached 97½°; on the 7th inst., 100°; and on the 8th, 103°, in the shade. The total number of insolations reported for these days amounted to about 75. On Sept. 9, 26 additional cases occurred. Nearly one-third of all the cases were fatal. Such excessive heat as that just recorded has not been experienced in New York since 1871.

—

New York State Health Board held a meeting at Niagara Falls on Aug. 11th, at which Dr. Harris, the secretary, read a paper proposing a plan of State vaccination for the purpose of eradicating variola. A resolution recommending the establishment of a State vaccine farm was carried. A resolution to the effect that the State Board co-operate with the National and local boards for the prevention of the introduction of variola into the United States, by emigration, was adopted. The Board has commenced to investigate the subject of adulteration of food in accordance with the provisions of a law recently enacted by the Legislature. The Board has appointed special officers to obtain and analyze samples of pharmaceutical preparations, and of the most commonly adulterated varieties of food. Among those claiming special attention are cheese, milk, butter, sugar, quinia, beer, honey, molasses, syrups, fish, baking-powders, soda-water, ice cream, teas, cocoa, canned fruits and extracts, wines and spirits.

—

Regulation of Medical Practice in New York.—On August 8th Dr. A. M. Purdy, President of the New York County Medical Society, appeared in behalf of the Society in the Police Court as complainant against three unlicensed medical practitioners. The offenders were each placed under $500 bail to await examination. The censors of the society in question are determined to deal summarily with prescribing druggists and unqualified practitioners.

—

Honours to the Secretary-General of the London Congress.—It is gratifying to find that the valuable services of Mr. Mac Cormac in organizing the London Congress are being recognized outside of his own country, and the profession will

learn with pleasure that, in addition to the honour of knighthood which Queen Victoria has intimated that it is her pleasure to confer on Mr. Mac Cormac, he has also received from France the Cross of the Legion of Honour.

—

Transactions of the International Medical Congress.—We learn that the Transactions of the London Congress will probably fill three bulky volumes, and that the first volume, containing the Addresses, will be put to press immediately.

—

Abatement of Noxious Odours.—The Committee on Hygiene of the New York County Medical Society is at present interesting itself with the abatement of noxious odours emanating from city stables, and with the prevention of smoke from kindling-wood and box factories.

—

The New York City Health Board is rigidly enforcing the act pertaining to the registration of plumbers and to the submission of their plans, for new plumbing work, to the Board for approval. The result of this commendable legislation has been to materially improve the drainage and ventilation of all recently constructed houses.

—

Prize Essay of the American Medical Association.—The committee of selection appointed by the chairman of the section on Practical Medicine, Materia Medica, and Physiology, at the June meeting of the American Medical Association, have selected, and announce, as the subject for the prize to be awarded in 1883, the following question:—

"What are the special modes of action or therapeutic effects upon the human system, of water, quinia, and salicylic acid, when used as antipyretics in the treatment of disease?"

The essays must be founded on original experimental and clinical observations, and must be presented to the chairman of the committee of *award* on or before the first day of January, 1883.

—

OBITUARY RECORD.—At Breslau, on August 10th, of kidney disease, in the fifty-second year of his age, Dr. OTTO SPIEGELBERG, Professor of Midwifery and Director of the Obstetric Clinic in the University of Breslau.

Dr. Spiegelberg graduated at Göttingen in 1853, and in 1858 published his first work, a *Compendium of Midwifery*. In 1861, he was appointed Professor of Obstetrics and Gynæcology in the University of Freiburg. In 1864, he accepted a similar professorship at Königsberg; and in 1865 accepted the professorship at Breslau. Since that time, he has been distinguished for literary activity. In conjunction with Dr. Credé, of Leipsic, he established the *Archiv für Gynäcologie*, of which seventeen volumes have appeared, and which contain numerous contributions by himself and his assistants. About five years ago, he published a *Text-book of Midwifery*, the second edition of which he had almost completed at the time of his death. He distinguished himself by his readiness to adopt all new improvements in the obstetric art. The first ovariotomy in Breslau was performed by him, and he operated in all in considerably more than one hundred cases. By his death, the obstetric branch of medicine has, in Germany, suffered a severe loss.—*British Med Journal*, Aug. 20, 1881.

—

To Readers and Correspondents.—The Editor will be happy to receive early intelligence of local events of general medical interest, or which it is desirable to bring to the notice of the profession. Local papers containing reports or news items should be marked.

TAYLOR'S MEDICAL JURISPRUDENCE—New Edition—Now Ready.

A MANUAL OF MEDICAL JURISPRUDENCE. By ALFRED S. TAYLOR, M.D., late Lecturer on Medical Jurisprudence and Chemistry in Guy's Hospital, London. Eighth American edition. Edited by JOHN J. REESE, M.D., Professor of Medical Jurisprudence and Toxicology in the Univ. of Penna. In one large and very handsome 8vo vol. of 933 pages, with illustrations. Cloth, $5; leather, $6; very handsome half Russia, raised bands, $6 50.

The American editions of this standard manual have for a long time laid claim to the attention of the profession in this country; and that the profession has recognized this claim with favor is proven by the call for frequent new editions of the work. This one, the eighth, comes before us as embodying the latest thoughts and emendations of Dr. Taylor, upon the subject to which he devoted his life, with an assiduity and success which made him *facile princeps* among English writers on medical jurisprudence. Both the author and the book have made a mark too deep to be affected by criticism, whether it be censure or praise. In this case, however, we should only have to seek for laudatory terms.—*Am. Journ. of Med Sciences*, Jan. 1881.

We are informed that the late Dr. Taylor took special pains in revising this edition of his well-known text-book, and a perusal of the volume fully bears out that statement. As it stands, with the additions made by Dr. Reese and the previous editors, it is not only an excellent manual for students, but also an ample work of reference.—*N. Y. Med. Journal*, March, 1881.

BRYANT'S SURGERY—New and Revised Edition—Just Ready.

THE PRACTICE OF SURGERY. By THOMAS BRYANT, F.R.C.S., Surgeon to Guy's Hospital, London. Third American, from the Second and revised English edition. Thoroughly revised and much improved, by JOHN B. ROBERTS, M.D. In one large and very handsome imperial octavo volume of over 1050 pages, with 767 illustrations. Cloth, $6 50; leather, $7 50; very handsome half Russia, raised bands, $8.

Dr. Roberts's annotations to the present work are not merely numerous, concise, and judicious, but they evince such acquaintance with surgical practice on both sides of the Atlantic as to afford a certain guarantee that this volume is brought fully abreast with the general surgery of the period.—*Am. Practitioner*, April, 1881.

For medical students this is one of the most valuable works on surgery, embodying, as it does, the views and experience of so eminent a surgeon as Dr. Bryant. The illustrations are all that could be desired. The additions of the American editor are most practical, and one wishes that they were more numerous.—*Chicago Med. Examiner*, May, 1881.

The author has spared no pains to keep it up to date, additions have been made here and there throughout the text, and many new illustrations have been inserted, so that it retains its place among the best of the text-books. It has always been a book which derived its chief value from the authority of its statements—the authority of a surgeon of large experience and much talent. It has always been a satisfactory book to turn to in time of doubt for the guidance of the experience and judgment of one man and he one who had the right to speak and spoke in no doubtful language.—*N. Y. Medical Journal*, June, 1881.

EMMET'S GYNÆCOLOGY—New Edition—Just Ready.

THE PRINCIPLES AND PRACTICE OF GYNÆCOLOGY. By THOMAS ADDIS EMMET, M.D., Surgeon to the Woman's Hospital of the State of New York, etc. Second edition, thoroughly revised. In one very handsome octavo volume of 875 pages, with 133 illustrations. Cloth, $5; leather, $6.

It needs no words from us to commend to all our readers this embodiment of the experience and observations of the eminent New York gynæcologist. It is a complete, systematic treatise upon all the diseases which properly belong to this branch of medicine. To the specialist this work is simply indispensable, and at the same time our general practitioners will find here a complete fund of information on all points concerning the uterine derangements of their female patients.—*Canada Med. and Surg. Journ.*, July, 1880.

Emmet's work, taken as a whole, is so rich in contents, and so excellent in performance, that every professional man can profit himself by it, and it has secured for itself an enduring place in gynæcological literature.—*Prager Medicinischen Wochenschrift*, 1879.

Its great merit consists in this—coming as it does from a thoroughly honest, competent, and able specialist, who became a specialist only after an excellent training and experience as a general hospital physician and surgeon. The book is not one to be hastily glanced over, but will secure the critical study of gynæcologists. Not only its style, which is individual and somewhat peculiar, but the new facts which it brings out, its original suggestions, its numerous and important statistical tables and, in some instances, its unexpected deductions, will compel attention, and will form the basis for a great deal of gynæcological study and literature in the future. All who make themselves familiar with the contents of this volume, will feel assured that Dr. Emmet has well earned and well deserved the reputation which he has already won, as one of the great gynæcologists of the present age.—*The Am. Journ. of Obstetrics*, April, 1879.

LEISHMAN'S MIDWIFERY—Now Ready.

A SYSTEM OF MIDWIFERY, INCLUDING THE DISEASES OF PREGNANCY AND THE PUERPERAL STATE. By WILLIAM LEISHMAN, M.D., Regius Professor of Midwifery in the University of Glasgow, etc. Third American edition, revised by the author, with additions by JOHN S. PARRY, M.D., Obstetrician to the Phila. Hospital. In one large and very handsome octavo volume of 733 pages, with over 200 illustrations. Cloth, $4 50; leather, $5 50; half Russia, raised bands, $6.

We gladly welcome the new edition of this excellent text-book of midwifery. The former editions have been most favorably received on both sides of the Atlantic. In the preparation of the present edition the author has made such alterations as the progress of obstetrical science seems to require, and we cannot but admire the ability with which the task has been performed. We consider it an admirable text-book for students during their attendance upon lectures, and have great pleasure in recommending it. As an exponent of the midwifery of the present day it has no superior in the English language.—*Canada Lancet*, Jan. 1880.

HENRY C. LEA'S SON & CO.—Philadelphia.

PROSPECTUS FOR 1881.

THE AMERICAN JOURNAL OF THE MEDICAL SCIENCES.

In commencing its sixty-first year, the publishers of the "AMERICAN JOURNAL OF THE MEDICAL SCIENCES" have much pleasure in assuring its wide circle of readers that at no period has it had the prospect of a more extended field of usefulness.

For 1881 the "American Journal" has the promise of its usual variety of important contributions from distinguished members of the profession in all parts of the country. Special attention will be bestowed, as heretofore, on its Bibliographical Department and Quarterly Summaries to keep its subscribers informed as to all subjects of professional interest from every quarter.

With its attendant periodical, "THE MEDICAL NEWS AND ABSTRACT," it combines the advantages of the elaborate preparation which can be given to a quarterly, and the prompt conveyance of intelligence by the monthly, while, the whole being under a single editorial supervision, the subscriber is secured against the duplication of matter inevitable under other circumstances. These efforts the publishers seek to second by offering these periodicals at a price unprecedentedly low—a price which places them within the reach of every practitioner, and gives the equivalent of three large octavo volumes for the comparatively trifling cost of FIVE DOLLARS *per annum*.

The "NEWS AND ABSTRACT" consists of sixty-four pages monthly, in a neat cover. It contains a CLINICAL DEPARTMENT in which will be continued the series of ORIGINAL AMERICAN CLINICAL LECTURES, contributed by gentlemen of the highest reputation throughout the United States, together with a choice selection of Foreign Lectures and Hospital Notes and Gleanings. Then follows the "MONTHLY ABSTRACT," systematically arranged and classified, and presenting five or six hundred articles yearly; each number concluding with an EDITORIAL and a NEWS DEPARTMENT, giving current professional intelligence, domestic and foreign, the whole fully indexed at the close of each volume, rendering it of permanent value for reference.

The subscription price to the "NEWS AND ABSTRACT" will be Two Dollars and a Half per annum, invariably in advance, at which rate it will rank as one of the cheapest medical periodicals in the country. But it will also be furnished, free of all charge, in commutation with the "AMERICAN JOURNAL OF THE MEDICAL SCIENCES," to all who remit FIVE DOLLARS in advance, thus giving to the subscriber, for that very moderate sum, a complete record of medical progress throughout the world, in the compass of about two thousand large octavo pages.

These terms may be recapitulated as follows:—

TERMS FOR 1881.

The AMERICAN JOURNAL OF THE MEDICAL SCIENCES, published quarterly (1150 pages per annum), and
The MEDICAL NEWS AND ABSTRACT, published monthly (768 pages per annum),
} Five Dollars per annum, in advance.

SEPARATE SUBSCRIPTIONS TO

The AMERICAN JOURNAL OF THE MEDICAL SCIENCES, when not paid for in advance, } Five Dollars.
The MEDICAL NEWS AND ABSTRACT, invariably in advance, Two Dollars and a Half.

*** Advance-paying subscribers can obtain, at the close of the year, cloth covers, gilt lettered, for binding the volumes of the JOURNAL (two annually) and the NEWS AND ABSTRACT (one annually), free by mail, on remitting ten cents for each cover.

The safest mode of remittance is by bank check or draft, or postal money order drawn to the order of the undersigned. Where these are not accessible, remittances for the "JOURNAL" and "NEWS AND ABSTRACT" may be made at the risk of the publishers by forwarding in REGISTERED letters. Address

Clinical Lectures.

ON INJURIES OF THE SPINE.

A CLINICAL LECTURE.

BY WILLIAM HUNT, M.D.

SENIOR SURGEON TO THE PENNSYLVANIA HOSPITAL.

GENTLEMEN: The years circling about 1850 were troublesome times in Philadelphia. Political differences, race prejudices, an inefficient police, and, more than all, a volunteer fire department were causes of disorder and riot which at times raged rampant. The typical firemen of that day represented a race which is now extinct. Jakey, Mose, and Sykesey have disappeared. The only impress they have left is one upon the language of political slang. To "run with the machine," in those days meant what it said; now it means absolute fealty to party and obedience to the "boss."

What characters they were!

The rough of to-day only replaces them in his roughness. In no other respect does he resemble them. One of the most noble motives that can incite men to great deeds was the cause of their existence, that of saving life and property from destruction by fire. But the same enthusiasm that led them to do this, with a bravery and a risk to life and limb that were both reckless and astonishing, also excited such rivalry among the different organizations, that bitterness, enmity, and hatred, leading to frequent riots and bloodshed, were the result.

Jakey was a picture, with a high cocked hat surmounting his soap-locks, generally close shaved, except before parade days, when the big fellows let their beards grow, so as to appear as ferocious pioneers with their fire axes, prognathous, a defiant leer on his lip, between his teeth a segar held so tightly that its free end took an upward pitch, neck long, sinewy and open, a red cravat loosely tied with a large bow under a low-down collar, except when there was a red shirt, lithe and long of limb, arms akimbo and swinging free from the shoulder, a rough coat, long boots, with trowsers turned up at the bottom, here we have Jakey, brave to a fault and ready at any time for a fire or a fight.

Now what, I hear you say, has all this to do with a clinical lecture? It has this to do with it, that these same brave, rough and ready fellows,

always had a respectable quota of their number, whether from fire or battle, in the wards of this hospital. After a riot they fairly filled it. Let me give you an idea of the times we went through. I lived here day and night, in the latter part of 1849 and through the years 1850 and 1851. This was the only accident hospital at that time of any account in the city, and as a matter of course, nearly all of the wounded were brought to it. The firemen were generally good and grateful patients. Many a Moya, Fairmount, Goodwill, or Perseverance Hose fellow would have willingly risked his life for me. I nearly laid down my life for them. Two young resident doctors succumbed and died, greatly owing to their over-work and exposure in the house. I had an attack of typhoid fever, which became historic, and was a theme for the medical lecturers, in their clinics, for many years. I had, according to the opinions of most distinguished attendants (Drs. G. B. Wood, W. W. Gerhard, and the elder William Pepper), every symptom of having perforation of the bowels. The accident was made out completely, but I treated science so disrespectfully as to get well, and so gave no opportunity to confirm the diagnosis.

After one riot (which, by the way, I believe was more a riot of the mob against the firemen than the firemen with each other), there were admitted no less than ten seriously wounded men. The slightly wounded were dressed and sent home. Gunshot wounds of the skull, trunk, and extremities were among them. Three alone of this lot died. So vivid is the impression of these times, that I remember the cases perfectly, their respective beds in the wards, and even the names of some of them. There was McShane, with his brains oozing from a depressed gunshot fracture of the skull; Westerhood, with his leg shattered by a bullet; Shearer, with his bad wound of the thigh, and the genial Jim Beesley of savory memory.

It is no exaggeration to say that in this hospital we saw more cases of gunshot wounds, through those disturbed periods, than were seen by most medical officers of the army and navy in the times before the war. But sad to say, it was not always the participant in the battles who were struck. Women and children on the outskirts of the crowds were sometimes the victims. In this way little Johnny Farley, aged eleven, was fatally wounded. He was brought into my ward, and I at once saw that he had a compound comminuted fracture of the head of the left humerus, which would probably require operative interference. He was in profound shock, and before sending a note calling the visiting surgeon on duty, I resorted to the usual means to bring about reaction.

This was the case that thus early in my surgical life strongly impressed me with the phenomena that occur in serious injuries to the spinal column and cord or to either of them. In those phenomena, I have ever since taken a deep, though melancholy scientific interest, melancholy, because of the utter hopelessness of recovery for most of the victims; scientific, because these and brain cases are those which give us more knowledge of the physiology of the nervous system than anything else.

They are cruel, accident vivisections, vivisections performed on the highest of God's creatures. I dislike vivisection, although I have done something at it in my day; but I have frequently thought when standing helpless at the bedside of one of these terrible cases of spinal injury, that if a dog could be wounded and give me any light for the relief of the man, it ought to be done. I think of him who said "ye are of more value than many sparrows," and I say ye are of more value than a few dogs.

Now note what happened. After Johnny had warmed up a little in bed, I turned down the covers to apply artificial heat to his feet. He complained of pains in his legs, and I noticed something that then surprised me. Gradually his penis began to swell, and in a few moments complete priapism was established. I then felt his feet, and tickled them on the soles; there was response and complaint, but soon no notice was taken of what I was doing. I brought my hands up the limbs and found that both sensation and the power of voluntary motion were gradually going; soon they were entirely gone. The pains disappeared; nothing was complained of or felt on either side below a line a little above the umbilicus. The case was clear. The ball had not only broken the humerus, but it had passed along the posterior aspect of the thorax, and had wounded the spinal column and cord, and I caught a view of the phenomena that were thus produced, *right in the act*, as clearly as if I had performed a vivisection in the same region. In this case the cord, as was shown *post mortem*, was not entirely compressed or lacerated, otherwise complete paralysis would have come on at once. Its gradual approach was explained by partial wounding and pressure, which latter was made complete through effusion of blood, as reaction came on, and the force of the heart was restored.

The fracture was of one of the dorsal vertebra, at or below the third, for there were no nerve symptoms involving the upper extremities. The brachial plexus and the intercosto-humeral nerves were not affected. It was a matter of indifference where the ball was. It had either passed on, or it was lodged in the column where in fact it was afterwards found. Johnny lived seventeen days. His may be taken as the type of an acute case of severe wound of the spine and cord. He passed through all of the phenomena incident to such cases, and had one (which I shall discuss fully further on) to an extreme degree. The priapism continued unabated for fourteen days. What else? There was complete paralysis both of sensation and motion on both sides downwards, from a line just above the umbilicus. The functions of organic life went on. The patient breathed, ate, and slept, and his food was digested, voluntary power over the bladder was lost, and the urine had to be drawn off with the catheter; the urine itself became ropy with mucus, ammoniacal and fetid. The bowels, at first torpid, relaxed, and there were involuntary stools. The pulse was always rapid. We did not take definite temperature in those days, but there were alternations of heat and cold. I was stricken with the sickness to which I have alluded, a few days before the death of the patient. My friend Doctor, now Professor, Penrose took charge of the case. The *post-mortem* examination completely confirmed the diagnosis. The line of injury was through the shoulder-joint into the chest and along its posterior face. The 4th or 5th dorsal vertebra was broken in fragments, the cord was lacerated, and the ball was found projecting into the spinal canal, where it was held and supported by spiculæ of bone. I looked over the University Museum yesterday for the specimen, where I thought it was; it was in the possession of Dr. Edward Peace, the chief surgeon for many years. I fear it has been lost.

I will now take up a case at the other end of my experience to this time, and then sum up what I have seen in a general way between the two periods. It also is typical, in that it illustrates a class which unfortunately are too common in accident hospitals. The victims truly "languish, and, languishing, they die."

Peter Green, adult, was admitted August 26, 1880. He died July 19, 1881—that is, 327 days after the injuries which killed him were received. He was in a stooping position, when a partition wall fell upon and crushed him.

The last dorsal and first lumbar vertebra were fractured, and a loose piece of one of them could be felt. There was immediate paralysis from the hips downward. In this case there was no priapism. The urine at first had to be drawn off with a catheter. The bowels were sluggish also, but soon became uncontrollable. Tympanites was a prominent feature. There was at times burning pain in the rectum. There was rapid emaciation, particularly noticeable in the limbs. At times there were attacks of local peritonitis. The pulse range for 42 days was from 108 to 72; temperature during the same period, 101½° to 98½°; and respiration averaged 22.43. After this, as the case became chronic, and was almost one thing from day to day, the records were not regularly kept. Bed-sores formed, the urine dribbled, the feces oozed out. But the brain was perfect, the heart was sound, as also were the lungs; the stomach performed its digestive duties.

If no fortunate accident intervenes, as hemorrhage, for example, there is nothing for such patients but to be worn out. Food and care prolong their lives to an indefinite extent. It is nothing but a question of endurance. Barring accident or intercurrent disease, death takes place at last through exhaustion, and sometimes suddenly, from heart embolism, a stoppage of the circulation occurring at once, and thus mercifully ending a life which might still further be prolonged. Peter died from exhaustion. There was no autopsy granted, nor was it necessary. The case was too well known to require it.

Now during the time between these two cases, I do not know how many of the kind I have seen and have had under my care.

I have had them injured in every region of the column, from the atlas to the sacrum, cervical, dorsal, and lumbar, and in various parts of these regions. Understand, they do not all die, but the slightly injured, and even seriously injured, provided the cord is not too much involved, may get entirely well, or make partial recoveries. Sometimes the paralysis remains through a full length of days, and the patient is otherwise in reasonably good health. Again, the paralysis may be partial, or one side may recover to a much greater extent than the other. It is much easier to understand these cases in an anatomical, physiological, and pathological sense, than it is to cure them. Those who get entirely well are, I think, mostly cases of shock to the cord, through injury to the column, without lesion of its contents. In a letter I have written about President Garfield's case,[1] I have described such a case as this which came under my care last summer, and which fully proved that such shocks occur, for I had my fingers directly on the broken vertebral bones in the operation for removing the ball. Symptoms of shock to the column were present at first, but they rapidly disappeared. The President's case was also one of the kind, but the wound was in an inaccessible place. The spinal symptoms having gone so soon, is it any wonder that the true diagnosis was missed?

How easy such a diagnosis is when the symptoms remain and are more or less permanent, as in those I have described. As the letter is published

[1] See page 700.

in this number of the *Medical News* it is unnecessary to allude to it further. To give you an idea of the number of cases that are sometimes under notice, I remember on one occasion that Dr. Weir Mitchell asked me to let him know when I had any of them in my wards, as he wished to study certain points about them. I was able at that very time to show him five—three on one side, and two on the other, of the long ward alone. I have not given you nearly all the points, but only the striking ones. This is a clinical lecture, and the subject is one for a volume. Volumes have been written on it. I have not referred to them, but only give you a hasty sketch of my own experience. I will now relate another case, to show what inflammation of the membranes and softening of the cord do, where there is no injury to the bone, and thus you will understand how the bones, provided they are not displaced, are not at all necessary factors in producing the dreadful symptoms I have described, and also how, through the application of anatomy and physiology, we are sometimes able to locate the trouble precisely.

In the summer of 1859, a gentleman, 52 years of age, began to complain of pain posteriorly, over a limited space, at the root of the neck, which at first was slight, but it was continuous and annoying. There were also sensations of a peculiar kind down both extremities, more of uneasiness and want of confidence than of pain. The fingers became numb, and things did not feel right in them; this was more noted in the right hand than the left, but only owing to the fact that the use of the right was wanted more than the left, and consequently its defects were noted. At this time there was no tottering in gait. Travel was tried for a few weeks, but the patient returned somewhat worse than when he went away. The symptoms were more pronounced. The pain was greater, the gait somewhat uncertain, a pen could not be held rightly. There was no trembling nor spasmodic jerking. The functions of the body were properly performed; the intellect was clear; there was some mental depression and anxiety. Business, however, was attended to. The patient was president of a corporation. Counter-irritants and other remedies were of no avail to check the progress of the disease.

The pains became more severe and sometimes were very bad; they did not spread, but were distinctly localized, and kept to the same region. The difficulties about the extremities grew worse. Finally the patient stayed at home, and soon took to his bed. His sufferings increased, and then he lost the use of all his limbs—of the legs first, and then of the arms. There was no priapism. The diagnosis was, that there was, first, a local spinal meningitis, and a subsequent inflammation and softening of the cord. The pain became intense; as a measure of the suffering I shall never forget what he said when the actual cautery was applied to the back. Dr. Joseph Pancoast, who attended the case with me, did the operation. The patient would not take ether, and as the white hot iron was seething through his skin and flesh, clear down to the bone, he said, "Oh, that is better than the pain!"

But all efforts to check the disease were in vain. Paralysis of the animal life of all parts below the root of the neck came on. Voluntary motion and sensation here were gone. We knew the part of the cord affected was below the origin of the phrenic nerve, for the diaphragm acted perfectly. It was by this muscle and through physical laws that the patient breathed. We knew the lesion was just below this nerve, for the parts supplied by the brachial plexus were paralyzed.

The intercostal muscles did not act. The abdomen became enormously distended, by reason of flatus accumulating in the bowels, the abdominal muscles having no power to control or repress it. In this case I did what I have never done since, although I have tried it. I have seen it denied in a French journal that it can be done. Regularly every morning, with a large stomach tube, which I passed as much as eighteen inches up the bowel, I drew off the flatus and relieved the pressure, as an engineer would relieve the pressure of steam on his boiler. The abdominal walls fell flaccid, but incapable of resisting, they arose again from the same cause in the following twenty-four hours. The urine, which early in the case had to be drawn away, now dribbled, and a flexible catheter was kept in the bladder. Peripheral nutrition was interfered with; there were huge sloughs of the skin, particularly of the back, in spite of all that wealth could purchase, in the way of peculiarly constructed beds and cushions, and all that the best nurses could do. The fault was within, and not without. The patient was vegetating below the root of the neck; all there was of animal life in him was above it. The heart, supplied from its cardiac plexus, most of which comes from above the origin of the brachial nerves, continued to act; the stomach did its digestion; the sympathetic nerve, which was not involved, regulated the secretions and the supply of blood to it, which in its turn it furnished with new material. But day by day there was loss, and death took place in the beginning of the following year, six months having been required with all these terrible things to destroy life. Now what was the cause of all this? The post-mortem examination, made by Dr. James Darrach and myself, showed it to be an inflammation of the membranes of the cord and a softening and destruction of the cord itself, for a space of about two and a half inches. The lesion was below the phrenic nerve, and where the cord gives off its branches to form the brachial plexus. *Everything else was normal.*

I will now detail a case of severe spinal *shock*. On the 6th of May, 1881, a man aged 21 was brought to the Hospital, paralyzed in both lower extremities. He fell from a height (about twenty feet) and landed directly on his feet. It was at first thought there was fracture of the lumbar vertebra, but nothing of this kind could be found on examination. Both calcanea were found to be fractured. The escape of the spinal column from severer injury was thus explained by the feet receiving the greater force of the blow, as much of it must have been expended in breaking such well-protected and thick bones. Enough of the shock however was transmitted to the spinal cord to produce most serious results. The paralysis of the left leg was not so great as that of the right one. There was dribbling of urine from loss of control of the bladder and over-distension. The catheter had to be used for a few days. There was no priapism. The bowels were torpid, and there was tympanites. There was much pain in the legs. Sensation was not affected at any time to the same degree as motion, although it was impaired. Nutrition went on uninterruptedly. The bones of the feet united as rapidly and as firmly as though nothing else was the matter. There was no particular trouble with bed-sores. To aid in preventing them the patient was at first put on a water-bed.

In a short time he became very tired of the unsteadiness of this, and asked for an ordinary bed. His request was granted without any bad result. Whilst his bones were mending, the spinal trouble was slowly and surely disappearing. Sensation improved quite rapidly. On the 31st of

the month the patient was able to lift the left leg. Through the following two months he gained power over the right one, and in the mean time perfect control was gained as to the other functions.

The injuries of the feet and cord together required the use of crutches after the patient left his bed. He soon learned to walk, and was discharged on the 31st of August.

Contrast this case with the one of gunshot fracture of the spine and that of myelitis or inflammation of the cord which I have given you, and there will be no difficulty in noticing the distinctions. Sometimes after such falls the feet take all of the force of the blow. I once saw a man who fell in the same way as the one I have just described, but from a much greater height. The bones of both legs were driven out at the ankle-joints, and the limbs had to be amputated. There were no spinal symptoms whatever in this case. Some cases of spinal shock are so severe as to go on to death through disorganization of part of the cord. Then the progress is like one of progressive myelitis.

The way in which the spinal cord is suspended in the canal without nearly filling it, as the brain fills the cavity of the cranium, is the reason that some surgeons deny the occurrence of spinal shock; what they mean is that some lesion takes place at the same time, for instance a local stasis of blood, or may be ruptures of small vessels. The same thing is more than likely true of many concussions of the brain, which all admit occur frequently. Concussions of the spine are of all grades from the unpleasant temporary jar that one gets when he is ignorant of or does not see a step in his way, and suddenly leaves a level, to the severe ones, such as that which has been described.

Railroad presidents and officials, and their lawyers, are the greatest skeptics about spinal concussion. The reason is, that it is the injury above all others that is simulated by dishonest claimants for damages after railroad accidents, so much so indeed that the name of "railroad spine" has absurdly been given to the cases. Spinal shock from other causes does not differ in its symptoms and progress from that which is produced on railroads. It is the degree of all of them that determines their gravity.

The possible results of a severe spinal shock can hardly be exaggerated. At the same time its symptoms and progress have been studied and imitated with a most astonishing minuteness. Judges, lawyers, and doctors have all been deceived, for after a supposed most pitiable victim of injury has recovered damages, he has also recovered health.

You should study these cases well, otherwise one of these doubting lawyers will twist you on the witness stand worse than the claimant's spine has been wrenched. I believe in spinal shock whatever its pathology may be, but I also know that it is a most difficult matter to distinguish the real from the spurious cases, especially where there is an insufficient or vague account of the accident which is supposed to have caused it.

I said I would discuss the symptom of priapism, which so often takes place after injuries to the spine, and which, if it does occur, is such a sure index of that injury. I have seen it follow, after accidents to all parts of the column, from the axis, of which I remember one particular case where it was present, down to the fifth lumbar vertebra. It is by no means a constant symptom. It may be but momentary, and, as we have seen, it may continue for days.

Also, as shown in the case I have last described, it is not apt to come on in disease of the membranes and cord, not the result of injury.

It may show itself rather late in such a case by extension outwards, but I have never met with it.

All these facts are puzzling, and I have never found a satisfactory explanation of them until now it dawns upon me. I suppose the same thing is in some book or lecture, but I have never seen it, and can not look for it now. I know this: that I have asked men most learned in nerve matters about it, and they have given me no satisfaction, and have acknowledged the puzzle. The fact is, we do not want the cerebro-spinal axis at all to explain it. Hilton, I think, goes to the brain for a reason for it, but we do not want the brain. We want the brain and axis to explain normal erection where there is sensation accompanying it, for in the form I am considering there is no sensation.

Now call to mind the sympathetic system of nerves. It is composed of a chain of ganglia and peculiar nerves lying along the spinal column, on the outside of the vertebral bodies, near the junctions of the ribs with the vertebra, and the intervertebral foramina, in the dorsal region; further forward on the bodies, in the lumbar region; and latterly with very long ganglia, in the cervical region.

Again, you all remember the rabbit that is brought out, in the lectures on inflammation, to show how the bloodvessels of the ear become engorged when the sympathetic nerve is divided in the neck. Whatever else this nerve may do, it is acknowledged to be the great vaso-motor regulator of the bloodvessel system; it is, as Draper says, the "fly-wheel" of the economy. The fibres of this nerve are abundantly distributed along the spermatic cord, which is mainly composed of the bloodvessels of the genital organs and the spermatic duct. In a normal erection the inhibitory power of the sympathetic is overcome by the fierce intensity of sexual emotion transmitted through the brain and cord. Local irritation through reflex also conquers the inhibition. This inhibitory power is also overcome when the trunk or ganglia of the sympathetic is abnormally irritated, lacerated, or divided. When this is the case, the blood rushes into and engorges the highly vascular tissue of the penis, and erection takes place, exactly as it rushes to the ear of the rabbit when the nerve is cut in the neck. If the ear was composed of what is called erectile tissue, which is highly vascular and elastic tissue, with fine muscular fibres, it would swell enormously from the same cause.

Thus it is not necessary to trouble one's self about a special nerve centre ruling over the function we are considering. Thus also this symptom in accidents to the column and cord is explained; also why some have it and others do not, why it is evanescent in some and in others almost constant, why it may appear in injuries occurring anywhere along the spine, why there is no sensation when it occurs as an accompaniment of laceration or pressure on the cord, for communication with the brain is cut off, and why also it is rare to find it in disease of the membranes or cord.

When the wounding missile or crushing force breaks the spine and involves the cord, and there is accompanying priapism, then the neighbouring ganglia or nerves of the sympathetic are bruised or wounded at the same time, from being caught in the line of the crush or wounding missile. When this symptom does not occur, the sympathetic has escaped. I have no doubt that when it occurs in hanging, the superior cervical ganglia of the nerve are caught in the squeeze. In most cases of disease the lesion is within the canal, and the sympathetic fibres or ganglia are not involved.

I shall say but little of the treatment of these cases. They are those

to which as much as any other class the popular solecism is applied, that "the doctor can do nothing for them," meaning that he cannot cure them. Do nothing for them? Why everything has to be done for them. The bad ones are themselves helpless.

How hospital nurses dislike to see them come into the wards! How hospital governors and managers deplore the expense of maintaining them! How residents and chiefs get tired of seeing them, day after day, slowly but surely losing ground! What a relief it is to make a morning visit and find the long occupied bed empty! There is respite for a while only, for soon another will come in. Individuals perish, the race survives, and so it is with accident and disease. We have their victims always with us. Where we cannot aid to bring about recovery, we can alleviate and prolong life, although, if we were the judges, we would often say it was not desirable to do so. The details, for instance, of what was done for Peter Green, during the 327 days he was in the hospital, would fill pages, and I have not time to give to them now.

ADDRESS ON PUBLIC MEDICINE.

Delivered at the Opening of Section XIII. State Medicine, of the International Medical Congress.

By JOHN SIMON, C.B., F.R.C.S., D.C.L., LL.D.

Gentlemen: In preventive, just as in curative, medicine, it occasionally happens that consequences more or less valuable result from some mere chance-hit of discovery; but, except so far as this may sometimes (and but very rarely) happen, disease can only be prevented by those who have knowledge of its causes—knowledge which does not deserve to be called knowledge, unless in proportion as it is conclusive and exact; and thoroughly to investigate the causes and their mode of operation is the quite indispensable first step towards any scientific study of prevention. Essentially, we know how to prevent by having first learnt exactly how to cause. Therefore it is that preventive medicine has had almost no development until within these later times. The germinal thought of it may be traced in even the first days of our profession. The spirit in regard of which Hippocrates has been aptly called the Father of Medicine—the scientific spirit of observation and experiment, as distinguished from the spirit of priestcraft, was one which his medical writings equally showed in their preventive as in their curative relations; and when he, some twenty-three centuries ago, expounded to his contemporaries that pathology is a branch of the science of nature—that causes of disease are to be found in physical accidents of air and earth and water, and in quantities and qualities of food, and in personal habits of life, he (not without risk of being denounced for impiety) virtually proclaimed for all time the first principle of preventive medicine, and indicated to his followers a new line of departure for those who would most largely benefit mankind. His followers, however, have had their work to do. True knowledge of morbific causes could only come by very slow degrees, and as part of the development with which the physical and biological sciences have, little by little, with the labour of ages, been building themselves up; and so no wonder that, despite the lapse of

time, even the most advanced of nations are hitherto but beginning to take true measure of the help which preventive medicine can render them.

Now what is the nature of that study of causes through which we may gradually arrive at counter-causing or prevention?

Addressing a skilled audience I shall utter what to them is the merest commonplace when I say that, in the physical and biological sciences, we acknowledge no other study of causes than that which consists in *experiment*. And the study of morbific causes is no exception to that rule; it is solely by means of experiment than we can hope so to learn the causes of disease as to become possessed of resources for preventing disease.

The experiments which give us our teaching with regard to the causes of disease are of two sorts—on the one hand we have the carefully prearranged and comparatively few experiments which are done by us in our pathological laboratories, and for the most part on other animals than man; on the other hand we have the experiments which accident does for us, and, above all, the incalculably large amount of crude experiment which is popularly done by man on man under our present ordinary conditions of social life, and which gives us its results for our interpretation.

When I say that experiments of those two sorts are the sources from which we learn to know the causes of disease, I, of course, do not mean that the mental process by which an experiment becomes instructive to us is the same in regard of the two sorts of experiment. On the contrary, the etiological problem (so long as it is a problem) is approached in the two cases from two opposite points of view; and the dynamical continuity of relation, which we call cause and effect, is traced, in the one case from the one pole, and in the other case from the other pole of the relation. In the one case, starting with knowledge of our own deliberately-prepared *cause*, our question is, What will be its effect? In the other case, starting from a certain *effect* presented to us, our question is, What has been its cause? But in the second case, just as in the first, when the question is answered, when the problem is solved, when the relation of cause and effect has been made clear, we recognize that the conjuring power which has brought us our new knowledge is the power of a performed experiment.

Let me illustrate my argument by showing you the two processes at work in identical provinces of subject-matter. What are the classical experiments to which we habitually refer when we think of guarding against the dangers of Asiatic cholera? On the one side there are the well-known *scientific* infection experiments of Professor Thiersch, and others following him, performed on a certain number of mice. On the other hand, there are the equally well-known *popular* experiments which, during our two cholera epidemics of 1848-9 and 1853-4 were performed on half a million of human beings, dwelling in the southern districts of London, by certain commercial companies, which supplied those districts with water. Both the professor and the companies gave us valuable experimental teaching as to the manner in which cholera is spread. I need not state at length the facts of those experiments, probably known to all here, but may rather justify my parallel by referring to an etiological question which will presently be discussed in our Section. It concerns the *causation of tubercle*—the most fatal by far of all the diseases to which the population of this country is subject. On that subject for the last sixteen years we have had a new era of knowledge. It was the great merit of a Frenchman, M. Villemin, that he, in 1865, first made us fully aware that tubercle is an infectious disease. He did this by certain laboratory experiments performed on other animals than man. He found that general and fatal tubercular infection of the animal was produced when he inoculated it subcutaneously with a little crude tubercular matter from the human

subject. That first laboratory investigation of the subject has been followed most extensively by others; and the further experiments, while entirely confirming M. Villemin's discovery, have shown that subcutaneous inoculation is not the only mode by which the tubercular infection can be propagated. Dr. Tappeiner and others have shown that the same effect is produced on the animal if tubercular matter (such as the sputa of phthisical patients) be diffused in spray in the air which the animal breathes; and Professor Gerlach, of Hanover, showed twelve years ago with regard to the bovine variety of tubercular disease (the Perseucht of the Germans) that its infection can be freely introduced through the stomach if bits of tubercular organs be given in the food, or if the healthy animal be fed with milk from the animal which has tubercle. That the communicability of tubercle from animal to animal is also being tested to an immense extent by popular experiments on the human subject is what a moment's reflection will tell; and from that wide field of experiment I select one instance for illustration. I have every reason to believe that Professor Gerlach's experiments on the communicability of tubercle by means of milk are very extensively parodied by commercial experiments on the human subject. I learn, on what I believe to be the highest authority in this country, that tubercle (in different degrees) is a malady which abounds among our cows; and that so long as the cow continues to give milk, no particular scruple seems to prevent a distribution of that milk for popular use. To the persons who consume that milk an important question as to the causability of tubercle is put in an experimental form. Whether they will become infected with tubercle is a question which the individual consumers do not stand forward to answer for themselves, like the animals of the laboratory experiments; but Dr. Creighton's lately published book, entitled "Bovine Tuberculosis in Man," and a paper in which I am glad to say he brings under notice of our Section the very remarkable series of facts on which he grounds that startling title, seem to suggest a first instalment of answer in accordance with Professor Gerlach's experimental finding.

The two sorts of experiment—the scientific and the popular—differ, as I have noted, in this particular: that the popular experiment is almost always done on man; the scientific almost always on some other animal. It is true that many memorable cases are on record, where members of our profession have deliberately given up their own persons to be experimented on by themselves or others for the better settlement of some question as to a process of disease; have deliberately tried, for instance, whether, in this way or in that, they could infect themselves with the poison of plague or of cholera; and as regards one such case which is in my mind, I think it not unlikely that the illustrious life of John Hunter was shortened by the experiments which he did on himself with the ignoble poison of syphilis. There have been cases, too, where criminals have been allowed to purchase exemption from capital or other punishment at the cost of allowing some painful or dangerous experiment to be performed on themselves. And cases are not absolutely unknown where unconsenting human beings have been subjected to that sort of experiment. But waiving such exceptions, the rule is, as I have said, that scientific experiments relating to causes of disease are performed on some animal which common opinion estimates as of lower importance than man. Now, as between man and brute, I would not wish to draw any distinction which persons outside this room might find invidious; but, assuming for the moment that man and brute are of exactly equal value, I would submit that, when the life of either man or brute is to be made merely instrumental to the establishment of a scientific truth, the use of the life should be economical. Let me, in that point of view, invite you to compare, or rather to contrast with one another, those two sorts of experiment from which we have to

get our knowledge of the causes of disease. The commercial experiments which illustrated the dangerousness of sewage-polluted water-supplies cost many thousands of human lives; the scientific experiments which with infinitely more exactitude justified a presumption of dangerousness, cost the lives of a few dozen mice. So, again, with experiments as to the causation of tubercle; judging from the information which I quoted to you, I should suppose that the human beings whose milk-supply on any given day includes milk from tubercular cows might be counted, in this country, in tens of thousands; but the scientific experiments which justify us in declaring such milk-supply to be highly dangerous to those who receive it were conclusive when they amounted to half a dozen. So far, then, as regards the mere getting of experimental knowledge, we must not, with a view to economy of life, be referred to popular, rather than scientific, experiment. And, in the same point of view, it perhaps also deserves consideration that the popular experiments, though done on so large a scale, very often have in them sources of ambiguity which lessen their usefulness for teaching.

Let me now briefly refer to the fact that, during the last quarter of a century, all practical medicine (curative as well as preventive) has been undergoing a process of transfiguration under the influence of laboratory experiments on living things. The progress which has been made from conditions of vagueness to conditions of exactitude has, in many respects, been greater in these twenty-five years than in the twenty-five centuries which preceded them; and with this increase of insight, due almost entirely to scientific experiment, the practical resources of our art, for present and future good to the world, have had, or will have, commensurate increase. Especially in those parts of pathology which make the foundation of preventive medicine, scientific experiment in these years has been opening larger and larger vistas of hope; and more and more clearly, as year succeeds year, we see that the time in which we are is fuller of practical promise than any of the ages which have preceded it. Of course, I cannot illustrate this at length, but some little attempt at illustration I would fain make.

First let us glance at our map. When we generalize very broadly the various causes of death (so far as hitherto intelligible to us), we see them as under two great heads, respectively autopathic and exopathic. On the one hand there is the original and inherited condition under which to every man born there is normally assigned eventual old age and death, so that sooner or later he "runs down" like the wound-up watch with its ended chain; and, as morbidities under this type, there are those various original peculiarities of constitution which make certain individual tenures of life shorter than the average, and kill by way of premature old age of the entire body, or (more generally) by quasi-senile failure of particular organs. On the other hand, as a second great mass of death-causing influence, we see the various interferences which come from outside; acts of mechanical violence for instance, and all the many varieties of external morbific influence which can prevent the individual life from completing its normal course.

As regards cases of the first class—cases where the original conditions of life and development are such as to involve premature death (which in any such case will commonly show itself as a fault in particular lines of hereditary succession)—the problem for preventive medicine to solve is, by what cross-breeding or other treatment we may convert a short-lived and morbid into a long-lived and healthy stock; and this, at least as regards the human race, has, I regret to say, hardly yet become a practical question. But as regards cases of the second class, evidently the various extrinsic interferences which shorten life have to be avoided or resisted, each according to its kind; and here it is that the scientific experimenters of late years have been giving us almost daily increments of knowledge.

Two early instances, vastly important in themselves, though of a comparatively

crude kind, I have already mentioned; and I now wish to glance at some illustrations of the immense scope and marvellous exactitude of the newer work.

The invaluable studies of M. Pasteur, beginning in the facts of fermentation and putrefaction, and thence extending to the facts of infectious disease in the animal body, where M. Chauveau's demonstration of the particulate nature of certain contagia came to assist them—they, I say, partly in themselves, and partly in respect of kindred labours which they have excited others to undertake, have introduced us to a new world of strange knowledge. We have learnt, as regards those diseases of the animal body which are due to various kinds of external cause, that probably all the most largely fatal of them (impossible yet to say how many) represent but one single kind of cause, and respectively depend on invasions of the animal body by some rapidly self-multiplying form of alien life. This doctrine, which scientific experiment initiated, has for the last dozen years been extending and confirming itself by further experiment. As soon as the doctrine began to seem probable, science saw that, should it prove true, it must have been the most important corollaries. If the cause of an infecting human disease is a self-multiplying germ from the outside world, the habits of that living enemy of ours can be studied in its outside relations. It becomes an object of common natural history; it has biological affinities and analogies. We can cultivate it in test-tubes in our laboratories, as the gardener would cultivate a rose or an apple, and we can see what agrees and what disagrees with its life. And then, as the next and immeasurably most important stage, where nothing but experiment on the living body will help us, we can try whether perhaps any of our modifications of its life have made it of weaker power in relation to the living bodies which it invades, or whether, through our more intimate knowledge of its vital affinities, we can artificially give to bodies which it would invade a partial or complete protection against it. Such, at first blush, were the obvious possibilities of research which the new doctrine of infectious disease suggested to the mind of the pathologist; and never since the profession of medicine has existed had a field of such promise been before it. The promise has not been belied. A host of diseases has been worked at in such lines as I just now indicated, and with many of them important progress has been made.

It would be impossible for me even to name a twentieth part of the investigations which have been more or less successful. As regards some which have most struck me, I pass with but a word—Dr. Klein's investigation of the pneumo-enteritis of swine; Professor Cohn's and Dr. Koch's and Dr. Buchner's respective contributions to the natural history of the anthrax bacillus; Dr. Böllinger's recognition of the microphytic origin of an important cancroid disease of horned cattle; with Dr. Johne's illustration of the inoculability of this disease; the research of Drs. Klebs and Tommasi-Crudeli into the intimate cause of marsh-malaria; and, not least, the demonstration (as it appears to be) which Dr. Grawitz has recently published, that some of the commonest and most innocent of our domestic microphytes can be changed by artificial culture into agents of deadly infectiveness. I pass these and others in order that I may more particularly speak of some which have already shown themselves practically useful; for in respect of some of them the time has already come when abstract scientific knowledge is passing into preventive and curative act.

First, and not in a spirit of national partiality, I will mention the application which M. Pasteur's doctrine has received at the hands of Mr. Lister, with regard to the antiseptic treatment of wounds, an application which, enforced and illustrated at every turn by Mr. Lister's own eminent skill as an experimentalist, has been confirmation as well as application of the parent doctrine, and the beneficent uses of which, in giving comparative safety to the most formidable surgical opera-

tions, and in immensely facilitating recovery from the most dangerous forms of local injury, are recognized—I think I may say by the grateful common consent of our profession in all countries—to be among the highest triumphs of preventive medicine.

Secondly, out of the experimental studies of anthrax—chiefly out of those of Dr. Sanderson and Mr. Duguid in this country, and those of Dr. Buchner in Germany, and M. Toussaint in France—has grown a knowledge of various ways in which the contagion of that dreadful disease can be so mitigated that an animal inoculated with it, instead of incurring almost certain death, shall have no serious illness; and the further knowledge has been gained that the animal submitted to that artificial procedure is thereby more or less secured against subsequent liability to the disease. In other words, with regard to that disease, an infliction which sometimes spreads to man from his domestic animals, and one which in some parts of Europe is of serious consequence to agricultural interests, as well as to animal life, the later experimenters—of whom I may particularly name M. Toussaint, and our countryman, Professor Greenfield—seem to be giving to the animal kingdom, and to the farmers, the same sort of boon as that which Jenner gave to mankind when he taught men the use of vaccination. Quite recently our great leader, M. Pasteur, seems to have made, by new experiments, still further progress in the mitigation of anthrax.

Thirdly, a similar discovery has been made by M. Pasteur, with reference to the contagium of a very fatal poultry disease, known by the name of fowl's cholera; he has learnt to mitigate that contagium to a degree in which, if fowls be inoculated with it, they will suffer no serious ailment, and he has found that fowls so inoculated—or, as he, in honour of Jenner, would say, "fowls so vaccinated"—are proof against future attacks of the disease.

Fourthly, Professor Semmer, of Dorpat, through experiments done under his direction by Dr. Krajewski, has made a similar discovery in regard to the infection of septicæmia—has found, namely, that, by treatment like that with which M. Toussaint mitigates the contagium of splenic fever, he can bring the most virulent septic contagium into a state in which it shall be mild enough to serve for harmless inoculations, which inoculations, when performed, shall be protective against future infections.

Finally, in a different direction of experimental work, let me name the recent most admirable research which Dr. Schüller, of Greifswald, has made, nominally in respect to certain surgical affections of joints, but in reality extending to the inmost pathology and therapeutics of all tubercular and scrofulous affections. A knowledge of the fatal infectiveness of crude tubercular matter has been given (as I before said) by Villemin and those who followed him, and Professor Klebs, four years ago, declared the infective quality to be due to the presence of a microphyte (micrococcus), which he had succeeded in separating from the rest of the matter by successive acts of cultivation in fluids of inorganic origin. Dr. Schüller solidly settles, and widely extends, that teaching. According to his, apparently quite unquestionable, observations and experiments, the micrococcus which characterizes tubercle characterizes also certain affections popularly called "scrofulous"—namely, "scrofulous" synovial membrane, "scrofulous" lymph-glands, and lupus; so that these diseases may be defined as essentially tubercular, and that inoculation with matter from any of them, or with a cultivation-fluid in which the micrococcus from any of them has been cultivated, will infect with general tuberculosis. The rapid multiplication of the tubercle-micrococcus in the blood and tissues of any inoculated animal can be verified both by microscopical observation and by inoculative experiment; and an extremely interesting part of the research in explanation of certain of our human joint-diseases is the demon-

THE

MEDICAL NEWS

AND

ABSTRACT.

EDITED BY

I. MINIS HAYS, A.M., M.D.

PHILADELPHIA:
HENRY C. LEA'S SON & CO
1881.

PUBLISHED MONTHLY AT $2.50 PER ANNUM IN ADVANCE.
Furnished in conjunction with the Quarterly American Journal of the Medical Sciences (in all nearly 2000 octavo pages) for $5.00 in advance.

Entered according to the Act of Congress, in the year 1881, by HENRY C. LEA'S SON & Co., in the Office of the Librarian of Congress. All rights reserved.

NEW MEDICAL BOOKS.

SMITH ON CHILDREN—New Edition—Just Ready.

A COMPLETE PRACTICAL TREATISE ON THE DISEASES OF CHILDREN. By J. Lewis Smith, M.D., Clinical Professor of Diseases of Children in the Bellevue Hospital Medical College, New York. Fifth edition, thoroughly revised and rewritten. In one handsome octavo volume of 836 pages, with illustrations. Cloth, $4 50; leather, $5; very handsome half Russia, raised bands, $6.

The opportunity afforded the author by the call for a new edition of his Treatise on the Diseases of Children has been taken advantage of to render the volume in every respect worthy a continuance of the professional confidence with which it has been favored in the past. Many portions of the work have been entirely rewritten, several additional diseases treated of, and much new matter introduced; but by the employment of a more condensed style of letter, the size of the work has not been materially enlarged. It will be observed that the very moderate price of the previous edition has not been increased

FOSTER'S PHYSIOLOGY—New and Revised Edition—Just Ready.

A TEXT-BOOK OF PHYSIOLOGY. By Michael Foster, M.D., F.R.S., Prof. of Physiology in Cambridge Univ., England. Second American, from the third English edition. Edited, with extensive notes and additions, by Edward T. Reichert, M.D., Demonstrator of Experimental Therapeutics in Univ. of Penna. In one handsome royal 12mo. volume of over 1000 pages, with 259 illustrations. Cloth, $3 25; leather, $3 75.

In the preparation of a second American edition of Mr. Foster's Physiology, the editor has endeavored to render it more than ever acceptable to the student as a clear and comprehensive text-book, presenting the science in its latest developments. The original work being an exposition of abstract physiology, without reference to the details of physiological anatomy, it seemed desirable to introduce some account of structure, in order to render more intelligible to the student the views and theories of the science. This the editor has added, in as concise a manner as possible; and in aid of this end has freely introduced illustrations from recognized authorities.

HARTSHORNE'S ESSENTIALS.—New Edition—Just Ready.

ESSENTIALS OF THE PRINCIPLES AND PRACTICE OF MEDICINE. A handy-book for Students and Practitioners. By Henry Hartshorne, M.D., Professor of Hygiene in the Univ. of Penna. Fifth edition, thoroughly revised and much improved. With 140 illustrations. In one handsome royal 12mo. volume of about 600 pages. Cloth, $2 75; half bound, $3 00.

The very great success which has exhausted four large editions of this work shows that the author has succeeded in supplying a want felt by a large portion of the profession. It has also enabled him in successive revisions to perfect the details of his plan and render the work still more worthy of the favor with which it has been received. In the present edition several hundred brief additions have been made, a number of new subjects have been written upon, especially in connection with the Pathology of the Nervous System, the illustrations have been considerably increased, and a large number of new and carefully selected formulæ for the administration of medicines have been introduced. An account is given also, in this edition for the first time, of the method of prescribing according to the metrical system, and a section is added upon Eyesight, its Examination and Correction. In presenting this edition, therefore, the publishers feel that it is in every way worthy a continuance of the favor hitherto accorded the work.

DALTON'S PHYSIOLOGY—New Edition—Shortly.

A TREATISE ON HUMAN PHYSIOLOGY. Designed for the Use of Students and Practitioners of Medicine. By John C. Dalton, M.D., Prof. of Physiology in the College of Physicians and Surgeons, New York, etc. Seventh edition, thoroughly revised and rewritten. With numerous illustrations on wood. In one very beautiful octavo volume of nearly 900 pages.

HAMILTON ON NERVOUS DISEASES—New Edition—In Press.

NERVOUS DISEASES; THEIR DESCRIPTION AND TREATMENT. By Allan McLane Hamilton, M.D., Attending Physician at the Hospital for Epileptics and Paralytics, Blackwell's Island, N.Y., and at the Out-Patients' Department of the New York Hospital. Second edition, thoroughly revised and rewritten. In one handsome octavo volume of about 600 pages, with numerous illustrations.

EDIS ON WOMEN—In Press.

THE DISEASES OF WOMEN. Including their Pathology, Causation, Symptoms, Diagnosis, and Treatment. A Manual for Students and Practitioners. By Arthur W. Edis, M.D., Lond., F.R.C.P., M.R.C.S., Assist. Obstetric Phys. to the Middlesex Hosp., late Phys. to the British Lying-in Hospital. In one handsome octavo volume with 149 illustrations.

COLEMAN'S DENTAL SURGERY—Shortly.

A MANUAL OF DENTAL SURGERY AND PATHOLOGY. By Alfred Coleman, L.R.C.P., F.R.C.S., L.D.S, etc.; Senior Dental Surgeon and Lecturer on Dental Surgery to St. Bartholomew's Hospital and the Dental Hospital of London. Thoroughly revised and adapted to the use of American Students by Thomas C. Stellwagen, M.A., M.D., D.D.S.: Prof. of Physiology at the Philadelphia Dental College. In one handsome volume with about 450 illustrations.

HENRY C. LEA'S SON & CO.—Philadelphia.

stration that if in the inoculated animal a joint is experimentally injured, that joint at once becomes a place of preferential resort to the micrococcus which is multiplying in the blood, and becomes consequently a special or exclusive seat of characteristic tubercular changes. Even thus far the practical interest of Dr. Schüller's book is such as it would not be easy to overstate, but still greater interest attaches to the last chapter of the book, in which, confidently resting on the pathological facts which I have quoted, he makes proposals for the treatment of tubercle on the basis of its microphytic origin, and shows the successful result of such treatment as he has hitherto tried from that basis on animals artificially infected by him.

I venture to say that in the records of human industry it would be impossible to point to work of more promise to the world than these various contributions to the knowledge of disease, and of its cure and prevention; and they are contributions which from the nature of the case have come, and could only have come, from the performance of experiments on living animals.—*Lancet*, Aug. 20, 1881.

Hospital Notes.

BELLEVUE HOSPITAL, NEW YORK.

(Service of Dr. AUSTIN FLINT, Sr.)

(Specially reported for the MEDICAL NEWS AND ABSTRACT.)

Chronic Nephritis. Uræmic Convulsions (Unilateral). Phthisis Pulmonalis.

Jennie C., æt. 40, Irish, domestic; admitted Sept. 20, 1881. About sixteen months since the patient had the initial lesion of syphilis, which was followed by secondary manifestations of the same disease. She was subjected to a course of treatment with mercurials, under the use of which the syphilitic symptoms disappeared in Aug. 1880. From that time until May, 1881, she enjoyed good health, having no prodromata of any disease whatever. At that time she suddenly became unconscious, and, falling to the ground, had several convulsions. Recovering from these, she pursued her ordinary avocations without applying for medical aid. Since then, however, she has had a convulsion almost every week, and sometimes twice a week. She has often bitten her tongue and foamed at the mouth during the convulsions, which have, however, been of brief duration, continuing only a few moments at any one attack. On Sept. 19, 1881, she had an unusually severe and protracted convulsion.

On admission (*September* 20, 1881), she was somewhat stupid, but conscious, and complained of loss of power in her left side. Suddenly, while undergoing examination, she became convulsed, the left side of the face and the extremities of the same side being most affected. The eyes were fixed, and blood-stained froth came from the mouth. Paroxysms similar to that just described recurred at short intervals during the night and on the following morning.

Physical examination revealed the second stage of phthisis pulmonalis at the left apex. The urine was acid and clear, had a specific gravity of 1021, and contained ten per cent. of albumen by volume, together with large and small hyaline and granular casts. The quantity of urine in twenty-four hours was ten fluidounces. Two drops of Ol. tiglii were administered, inasmuch as another uræmic convulsion was apprehended, and produced a small fecal evacuation.

September 21. The patient is still stupid, and has slight *subsultus tendinum*. One-tenth of a grain of elaterium was now exhibited every three hours until

three doses had been administered. The result of this medication was to produce several watery movements and to relieve the ataxic symptoms.

22*d*. The amount of urine for the past twenty-four hours has been only eight fluidounces. The patient had one attack of eclampsia in the morning, followed by profuse diaphoresis. She was placed upon the use of infusion of digitalis, one-half ounce, and bitartrate of potassium, one drachm, every three hours.

23*d*. Patient had two violent convulsions during the night, but soon completely recovered from them. Urine in twenty-four hours, sixteen fluidounces.

24*th*. One convulsion occurred during the night. Urine passed, thirty-six ounces. The same treatment is continued.

25*th*. Amount of urine, forty-seven ounces. No convulsion occurred.

26*th*. No eclampsia. Amount of urine, forty-two ounces. Appetite has returned.

28*th*. Amount of urine, thirty-seven ounces. It is clear, has a specific gravity of 1025, and contains albumen, 5 per cent., by volume, with a few granular and hyaline casts. The digitalis was discontinued.

October 8. No convulsions have occurred since last note. Patient's general condition has improved. Urine, forty ounces, and contains no casts, although some albumen still remains.

12*th*. The patient is so well as to desire her discharge.

—

Recurrent Fibroid Mammary Tumour.

An interesting case of this kind recently came before Mr. GAY, at the Great Northern Hospital. He had removed the mammary gland a twelve-month previously. There was no axillary complication, and the wound healed well in about three to four weeks. The patient was a lean person, aged fifty-four years. When she presented herself again, two painful growths had recurred on the axillary side of the site of the former operation, and had ulcerated on their surfaces. The bases were of almost a scirrhous hardness, but unadherent to the subjacent structures. The ulcerated surfaces were flattened, and had the appearance of being made up of eversion, from central gaps of the skin and, might be, allied structures.

Mr. Gay said he deemed the case one of considerable interest, as illustrating a by no means uncommon instance of fibro-recurrent or recurrent adenoid growth, such as he had described repeatedly in the Pathological Transactions, and which has a history, both clinical and pathological, of its own. Mr. Gay had no difficulty in distinguishing the case from absolute cancer, although it appears to stand close on the immediate confines of that disease. Originally a growth from the mammary fibrous structures, its recurrence is never prevented by the ablation of the gland. It is but slightly infective, so that the axillary glands do not show any marked disposition to enlargement, either by contamination or sympathy; and in the event of their becoming enlarged, the swellings usually either subside, or ulcerate after the fashion of the parent growths. It is at certain stages spindle-cell shaped in its histological characteristics. The tendency of these tumours to grow, as well as to ulcerative degeneration, is in the direction of the skin. They admit of removal in any stages of their career, and certainly with much temporary advantage to the patient, as the disease seems to have a specifically local character, and does not usually invade vital organs. On the other hand, with removal, the patient is very prone to improve in constitution, and to get healthy and fat. Such cases must have come under the observation of other surgeons; but, as far as Mr. Gay was informed, have not met with much attention.—*Lancet*, October 8, 1881.

MONTHLY ABSTRACT.

Anatomy and Physiology.

The Origin of the Liquor Amnii.

Dr. WIENER, of Breslau, has experimentally investigated upon dogs and rabbits the above subject, with special reference to the part played by the fœtal kidneys in the production of the amniotic fluid. His results are communicated to the *Archiv für Gynäcologie*. The amnion is of course a fœtal membrane, and therefore it might be supposed that, at least in the early months of pregnancy, the fluid within it was in some way furnished by the fœtus. From the fact that the liquor amnii contains urea, some have supposed that the fœtus passed urine into it. But some experiments which have been made by Kuntz, and confirmed by the author, show that when a solution of an indigo salt is injected into the maternal blood, the liquor amnii becomes coloured by the pigment, although none of it enters the fœtal circulation or stains the fœtal tissues. And according to Fehling and Ahlfeld, the secretion of urine by the fœtus during intra-uterine life is very scanty and slow. If these facts be correct, it would seem that the liquor amnii in the later months of pregnancy is mainly furnished by the mother, and that fœtal urine does not, as a rule, form a part of it. To determine both whether the kidneys act, and whether their secretion does add to the amount of the liquor amnii, Dr. Wiener injected the indigo solution, with a hypodermic syringe, directly into the fœtus. This, he says, is not difficult to do. He found that when introduced thus into the fœtal circulation, it was excreted by the kidneys, and tinged the liquor amnii. He concludes, therefore, that the kidneys do actively act in intra-uterine life; that the urine is passed into the amniotic sac; and that the liquor amnii largely consists of fœtal urine. His experiments give a little additional support to what might have been inferred from the facts, that, as mentioned, the liquor amnii commonly contains urea, and that in cases of malformation and occlusion of the fœtal urethra, the bladder and kidneys are found distended with urine.—*Med. Times and Gazette*, Oct. 8, 1881.

—

Heat Dyspnœa.

Several physiologists have lately turned their attention to the interesting phenomenon known as "heat" or thermal dyspnœa, and a *résumé* of the results obtained is given in the last number of the *Revue Scientifique*. It is well known that when the temperature of the blood increases, the respiratory rhythm becomes more frequent, dyspnœa supervenes, and those phenomena are observed which are properly attributable to exaltation of temperature. The interesting question arises, Where are the points of attack for the increased temperature? Does it act on the cerebral convolutions primarily, and through these on the respiratory centres, or does it act on the skin first, or on the pulmonary endings of the vagus first, or, finally, does it act directly on the nerve-centres which govern the respiratory movements? Goldstein believes he has proved that increased temperature does not act by way of the skin, because in a heated animal cold affusions do not at once destroy its effects; that it does not act through the cerebrum, or is owing to any feeling of uneasiness on the part of the animal, because it is not

prevented by morphia injected into the veins; that it does not act by the pulmonary expansion of the vagi, because it is not prevented by their section; but he endeavoured to show that it is occasioned by the direct action of heated blood on the respiratory nerve-centres by employing a method of increasing the temperature of the blood without exciting the sensory nerves at their periphery. This method consisted in exposing the carotid of a rabbit, and without otherwise disturbing the circulation through it, surrounding it with hot water, which of course heated the blood passing to the brain and medulla oblongata. Goldstein came to the conclusion that as heat dyspnœa then set in, it was clearly due to the action of the warm blood upon the respiratory nerve-centres. M. Gad and M. Mertchinsky have made a series of experiments on rabbits in this mode, and on registering by means of a pneumograph it was found that about thirty seconds after the heating of the carotidean blood the respiratory rhythm became four or five times more frequent, and ten seconds later heat dyspnœa was fully established. The same result was obtained by another experimenter, and in an article in M. Foster's *Journal of Physiology*, contributed by M. Sihler, that observer considered that it was attributable partly to pain and partly to an increase in the amount of carbonic acid contained in the blood, and to the augmented molecular changes naturally consequent on an elevated temperature. But this conclusion is disputed by the most recent experimenters, Mertchinsky and Gad, on the ground that the type of thermic dyspnœa differs from that of asphyctic dyspnœa. In heat dyspnœa respiration is short and shallow, whilst in asphyctic dyspnœa it is deep. According to Mertchinsky moderate doses of chloral do not modify thermic dyspnœa, whilst toxic doses almost entirely prevent it from supervening, or at least cause it to appear at a much later period and in a much less marked form. The section of the two pneumogastrics was without effect. Section of the fifth pair did not prevent it from occurring, but it was much less distinctly marked. Hence he concludes that it is not a reflex action consecutive to excitation of the sensory nerves of the face by heat. Moreover, the respiratory excitement is observed in as distinct a form after ablation of the encephalon as before. Hence Mertchinsky maintains that the type and rhythm of the respiratory acts depend on the temperature of the inspiratory nerve-centres situated in the medulla oblongata.—*Lancet*, Oct. 8, 1881.

Materia Medica and Therapeutics.

Absorption of Mercury.

After the inunction of the ointment of mercury in rabbits and men, FURBRENGER failed to discover any trace of mercury in the rete Malpighii of the skin, but globules were visible in the hair-follicles and in the sweat-ducts. If, however, the epidermis was first removed, the metal was then found in the corium, but only a few isolated globules could be seen in the deeper layers of the skin and in the subcutaneous tissue. After exposure to mercurial vapour no mercury could be found in the hair-follicles or sweat-ducts, although the surface of the skin was covered with a gray deposit. Twenty-four hours after an injection of a mercurial emulsion into the jugular vein the presence of dissolved mercury in the blood could be demonstrated in five out of eleven experiments, and the liver always contained mercury in a state of solution. Hence it seems certain that metallic mercury becomes dissolved in the blood. The metallic mercury in the hair-follicles was considerably diminished in quantity in eight days, and those globules which remained were oxidized on the surface, angular, and dirty-black in colour.

It is probable that the fatty acids of the skin assist in the solution. Oberländer has found that silver could be detected in the urine 190 days after the cessation of a course of inunction. The excretion was not, however, uniform, but presented remissions and exacerbations, the former occasionally of ten days' duration. A course of treatment by sulphur waters seemed to make no difference to the excretion, and no influence could be ascribed to salt baths, soda baths, or vapour baths. He concluded from his experiments that mercury is probably excreted largely by the liver and intestine. Although the action of mercury has been much studied, little attention has been given to the lesions which are found when death results from its action. Mering has produced in cats all the symptoms of chronic mercurial poisoning by injecting daily a solution of oxide of mercury in glycocoll—stomatitis, salivation, anorexia, diarrhœa, anæmia, prostration, albuminuria. After acute poisoning the autopsy uniformly revealed intense hyperæmia of the gastro-intestinal mucous membrane, and often actual erosions. The lesions were most intense in the lower part of the small intestine. Occasionally hemorrhages were found in the cardiac muscle, and ecchymoses in the bladder. The liver and kidneys were intensely congested. After chronic poisoning there was found a similar inflammation of the gastro-intestinal mucous membranes, ulceration in the small intestine, and a still more severe affection of the large intestine. Ulceration in the mouth and necrosis of the maxillary bones were also common. These effects are regarded less as due to a general cachexia than to the localized action of mercury on the different organs.—*Lancet*, Sept. 24, 1881.

—

Carbolic Acid as an Antipyretic.

At a recent meeting of the Soeiété de Biologie, M. RAYMOND gave an account of the markedly antipyretic qualities possessed by carbolic acid, which he has administered in cases of typhoid fever. The acid is given simultaneously by mouth and rectum, to the amount of one gramme per diem, fifty centigrammes being divided into three pills, and a like quantity used in enemata. He declares that its administration on this plan is very soon followed by a great reduction in temperature—viz., to the extent of 3° or 4° C., and within half an hour most profuse diaphoresis is established. To ascertain whether this hypothermic effect was produced by the direct action of the carbolic acid, or indirectly through the diaphoresis, M. Raymond suppressed the latter by the injection of duboisin, and found the lowering of temperature to be unaffected. He found also that the antipyretic action was increased the longer the administration was continued. By employing larger doses—viz., two grammes, toxic effects were produced, the temperature fell to 34°, convulsive tremors occurred, and carboluria appeared. At the suggestion of M. VULPIAN, carbolate of soda was given in doses of one gramme and a half, instead of the free acid, and the patient kept under the influence of the drug. The toxic effects did not appear, but the antipyretic action was still marked. The remedy does not, according to M. Raymond, limit the duration of the stages of typhoid fever; it controls the pyrexia of idiopathic erysipelas in a similar way, but has no influence on that of tuberculosis. It was pointed out that the antiseptic could not, of course, pass through the alimentary canal unchanged, so as to reach the ulcerated small intestine, and it would seem simply that it acted through the spinal cord and the vascular system.

M. HALLOPEAU thought the acid might have a topical effect on the typhoid ulcers. M. DUMONTPALLIER pointed out that it was not so good a regulator of the fever as refrigeration. M. HANOT made some curious observations, which he detailed more at length at the next sitting of the society. He said that in two

cases of adults suffering from typhoid fever, whom he had treated by carbolate of soda given internally, defervescence was determined on the fourteenth day in one case, and on the sixteenth in the other, the temperature falling 3° to 4° C. on the second or third day of treatment. In each case a peculiar rash appeared at the same time as the fall in temperature, the rash becoming pustular and varioliform in a short time. The pustules, on microscopical examination, were found to be formed almost wholly of bacteria mingled with a small amount of pus. The urine also contained bacteria. M. PAUL BERT, in commenting upon this, went so far as to say that carbolic acid renders the organism unfit for the development of the bacteria, and causes the particular material in which they thrive to be eliminated by the skin and kidneys, and the bacteria following its elimination are found in these parts. Upon what slender facts are marvellous and weighty theories sometimes raised!—*Lancet*, Aug. 20, 1881.

—

Merits of Hospital Kwass.

This, an old popular Russian drink, is included in the obligatory diet of the military hospitals in that country, being given out (in full diet) in allowances nearly one litre. Iljinsky, at the request of his senior medical officer, undertook the task of overlooking the preparation of the beverage, and daily analyzing it as to its contents of acids, alcohol, and extractive matter. For the preparation of 5496.161 litres (80 eimers), the following ingredients are made use of: Barley malt, 104.950 litres (4 tschetwerik); rye malt, 1638.4 to 4095.10 grammes (4 to 10 Russian pounds); rye meal, 24,570.60 grammes (60 Russian pounds); yeast, nearly ¾ of a litre (¾ of a "krug"); peppermint, 2047.55 grammes (5 Russian pounds); wheat meal, 819.2 grammes (2 Russian pounds). When brewed under observation, the specific gravity was 1012 to 1021, although formerly it was 1004 to 1006, and Dr. Georgievski gives 1006 to 1007 as the average specific gravity of kwass. Hence it appears that in general 70 per cent. of the officially determined quantities of ingredients are, for economical reasons, not used. The analysis showed it to contain a series of valuable nutritive constituents, thus: lactic acid (according to Preyer a nerve-sedative), acetic acid (a thirst-quencher), and, further, alcohol and carbonic acid, both of which hinder tissue change, and thus, to a certain extent, lower the temperature. The day's hospital ration of kwass contains: albuminates, 5.5 grammes; carbon hydrates, 33.0 grammes. The merits of the drink may be thus summed up: it excites appetite, acts both on the nervous system and on tissue-change, and is to a certain extent nourishing. When it is rapidly cooled after boiling, as is done with beer, a beverage resembling stout, but of more nutritive value, is obtained.—*London Med. Record*, July 15, 1881.

—

Fernet's Method of Introducing Food and Medicine by the Nostrils.

M. FERNET (*Revue de Thérap.*) wishes to popularize the method of introducing liquid or semi-solid elements, and certain drugs, by the nostrils. The author has seen it employed successfully in newly-born infants, too weak to take the breast or milk from a spoon. He proceeds as follows: The patient being laid on his back, a little raised, the end of a spoon or, better, the spout of a close vessel, is brought near to one nostril, and its contents are poured in gently at intervals. The liquid slides over the floor of the nasal fossæ and the roof of the palate, and reaches the pharynx, where it induces movements of regular deglutition. If the operation be well done, the liquid never returns by the other nostril. This method may be applied in certain cases of apoplectic coma, when the patient

cannot drink for three or four days successively, in the tuberculous meningitis of children, etc.—*London Med. Record*, July 15, 1881.

—

Preparations of Digitalis.

Dr. FRANKEL (*Charité-Annal.*, Band vi.) says, that the leaves of digitalis have an effect upon the circulation, which differs greatly according to their source, and possibly also to their freshness. The German Pharmacopœia prescribes a watery extract prepared from the pressed leaves; an alcoholic and an ethereal extract; and, finally, one obtained with the help of vinegar. The tincture is made by treating crushed portions of the fresh plant with six parts of alcohol; while the acetum is obtained by maceration of the dry leaves with a mixture of one part of alcohol and nine parts of vinegar. About ten grammes of the tincture are considered equal to one part by weight of the leaves of digitalis. Digitalis, when given in small doses, has a very different effect from that obtained by large quantities. The latter are chiefly administered in cases of acute inflammation, attended with fever, while the former are employed to remove the troubles observed in heart-disease, in the so-called stage of compensatory disturbance. While the effect of smaller doses (0.5 to 0.75 gramme daily) is retardation of the contractions of the heart with increased arterial tension, larger doses (1.0 to 1.5 gramme daily) are followed by diminished arterial expansion and reduced frequency of the pulse, not unfrequently accompanied by collapse and vomiting. These latter doses were therefore administered as an antiphlogistic and antifebrile in pneumonia, pleurisy, pericarditis, and acute rheumatism, especially when the disease was naturally inclining towards a crisis and recovery. Traube explained this influence of digitalis in reducing temperature by its action upon the vasomotor nervous system, and the vascular expansion of the skin especially. Traube's experiments have shown that the smaller doses in heart-diseases, by exciting the vagus nerve, retard the beating of the heart, and, by increasing the pressure of the aorta, regulate the adduction of a sufficient quantity of arterial blood to the myocardium, so that this organ recovers from its previous state of exhaustion, and is once more enabled to contract energetically. Only when the poisonous effect increases, paralysis of the cardiac nervous system and sinking of the blood-pressure set in. Böhm has since proved, by experiments on the exposed hearts of frogs, that digitalin has a specific effect upon the cardiac muscle itself, and upon the terminal branches of the vagus nerve connected with it, whereby the remarkable phenomena in the action of the heart are chiefly called forth. In order to test the activity of the different preparations of digitalis used in practice, dogs of middle sizes were curarized and injected subcutaneously with the infusion, the tincture and the acetum (the alcohol and vinegar having been removed), and the beginning of the retardation of the pulse and the enlargement of the single beats were considered as the commencement of the action. The following were the results. 1. The tincture, and also the acetum and the infusion of digitalis, are capable of exercising an exciting influence upon the inhibitory nerves of the heart, and upon the vaso-motor centre; but there are unmistakable grades of distinction in the action of the three preparations. 2. The tincture is the least reliable. 3. The action of digitalis—retarding of the pulse and increased blood-pressure setting in, after divers large doses of both the infusion and the acetum—sets in according to the individuality of the animals, and other accessory circumstances. 4. The acetum digitalis is the most powerful.—*London Med. Record*, Aug. 15, 1881.

Dangers of Peritoneal Transfusion.

Professor MOSLER (*Deutsch. Archiv für Klin. Med.*, vol. xxviii.) refers to the successful cases of Ponfick with injection of defibrinated blood into the abdomen (already recorded in the *London Medical Record*, vol. viii. p. 12), and to the observations which we have also recorded of Golgi and Bizzozero (*Ibid.*), indicating the excellent effect of such injections in increasing the richness of the blood, as tested by observations on the increase of blood-corpuscles and hæmoglobin. Mosler assumes as an indication for transfusion the leukæmic quality of the blood; and the observations of himself and others on the effect of transfusion in leukæmia indicate that it should be done repeatedly in similar cases. It could not as yet be repeated often enough, on account of the dangers and difficulties of transfusion into the vessels. It being reported by Ponfick and Bizzozero that peritoneal transfusion presented greater advantages, the author resolved to try it on his patients, and especially to study the influence of repeated transfusion in the same patient. The first patient who appeared adapted for peritoneal transfusion was a man, aged 27, who had had sixteen parenchymatous injections of Fowler's solution of arsenic into a chronic tumour of the spleen without any symptoms of irritation of the peritoneum. Peritoneal transfusion appeared to be indicated by the anæmia, which had set in in a very high degree; besides, it was of especial interest to be able to state whether the splenic tumour, which had considerably diminished after the injection of Fowler's solution, would show a yet greater diminution. After repeated peritoneal transfusion, microscopic examination of the blood showed, besides a diminution of the red corpuscles, a large number of microcytes. The origin of the tumour was referred to intermittent fever and syphilis. On December 8, 1880, 40 centigrammes of defibrinated blood were slowly injected, by means of a well disinfected injecting apparatus, through a puncture made in the left side of the abdominal wall. On the place of puncture a carbolized compress was laid, fastened with a gauze bandage; and above this a bag of ice was placed. In the morning and evening the patient received a dose of 15 milligrammes (nearly a fourth of a grain) of pure opium. He complained of pains in the place of puncture, both during the operation and for some time afterwards. The temperature in the evening was 38.4 deg. Cent. (101 deg. Fahr.); the following morning 37.2 deg. Cent. (99 deg. Fahr.); no alteration could be noticed in the urine and blood. On December 21, the peritoneal transfusion was repeated with the same apparatus. The place of puncture was the linea alba, about 7 centimetres below the navel. The transfusion, of 130 cubic centimetres of blood, was done gradually. The patient complained while the puncture was made, and also afterwards, of pains in the place of puncture, and upwards. Hourly measurements, after the transfusion, showed a moderate elevation of temperature. The pulse was 110 per minute. In the night the pains increased. On December 21, in the morning, the temperature was 39.6 deg. Cent. (103.3 deg. Fahr.), pulse 128; there were symptoms of peritoneal irritation. The abdomen was distended; he had considerable difficulty in breathing; the heart's action became irregular; and death occurred on the following night. The *post-mortem* examination showed diffuse peritonitis, a tumour of the spleen, and a high degree of syphilis of the liver. In this case, observation shows that peritoneal transfusion cannot be recommended in all conditions of the vascular system. The author suspects that the repetition of the transfusion was the cause of the peritonitis; since neither were the instruments dirty, nor was there any injury to the intestine, nor abnormality of the injected blood. In this case an interval of twelve days occurred between the two operations, in which the patient showed no signs of peritonitis. He is inclined

to think that the immediate cause of peritonitis here was an increased vulnerability of the peritoneum, due, probably, to the previous transfusion, as well as to the disease from which the patient suffered. He points out that peritoneal transfusion at short intervals must not be regarded as a harmless operation; and that it is probably contra-indicated in inflammatory and other diseases of the abdominal organs attended with a tendency to peritonitis.—*London Med. Record*, Aug. 15, 1881.

New Method of Producing Anæsthesia of the Larynx.

Prof. ROSSBACH, in the *Ann. des Maladies de l'Oreille, du Larynx, et des Organes Connexes*, Sept. 1881, describes his method, which consists in an attempt to suspend the conductibility of the trunk of the sensory nerve of the larynx so as to produce complete anæsthesia of that organ. The trunk of the sensory branch of the superior laryngeal nerve reaches the interior of the larynx by penetrating the thyro-hyoid membrane, below the extremity of the greater horn of the hyoid bone. At this point the nerve trunk is very superficial, and it is very easy, by means of ordinary agents, to destroy its conductivity. The author uses subcutaneous injections of morphia, 0.005 grm. at this point on both sides of the neck. Success was complete. He also found, by experiments made on healthy subjects, that the conductivity of this nerve could be suspended by cold. He used for this purpose a Richardson's atomizer, with two jets so arranged that the spray is thrown on both nerves at the same time. A spray of ether served in less than two minutes to render the interior of the larynx entirely insensible of contact with a foreign body. The author thinks that this method might be of use in cases of reflex spasm, where the point of departure is in the interior of the larynx, as well as in painful affection of this organ.

Medicine.

Presence of Bacilli in Typhoid Fever.

As a conclusion of his earlier communications on this subject, EBERTH reports the results of the examination of seventeen cases of typhoid fever. For the sake of comparison, he contrasts these cases with eleven examples of different forms of infection, in which, with the exceptional occurrence of micrococci in the lymphatic glands, no bacilli were found, and with thirteen cases of tuberculosis and phthisis, in which, in spite of the extensive ulceration of the intestinal canal, no allied forms of organism were found in the spleen or lymphatic glands. The ulceration of the intestine did not here, as in typhoid fever, favour the introduction of organic forms. Among the cases of typhoid fever, bacilli were found in six instances, especially in the infiltrated lymphatic glands, more seldom in the enlarged spleen, and in eleven cases they were absent. In the cases in which these organisms were found, as in his earlier observations, the duration of the disease was, as a rule, larger; the number of bacilli, however, with the exception of one case of fourteen days' standing, in which they were found in great abundance, was less. The bacilli agreed in their general characteristics with those previously described by the author and by Klebs; in addition, however, to the usual forms, longer and broader threads were noted, which were perhaps only other developmental forms.—*Centralblatt f. d. Med. Wissenschaft*, Sept. 10, 1881.

Treatment of Typhoid Fever by Salicylate of Soda.

M. CAUSSIDOU made a communication to the meeting of the French Association for the Advancement of Science at the Congress of Algiers, which was based on thirty-two cases of typhoid fever treated by salicylate of soda, and in which the rise of the temperature and the influence of this drug on the febrile process had been registered with the greatest care, as attested by numerous tracings shown by the writer. M. Caussidou arrived at the conclusion, in opposition to the facts observed in several wards of the Paris hospitals, that salicylated medication gives larger, more certain, and more permanent effects than refrigeration. M. Caussidou has even been in doubt if, by administering salicylate of soda from the outset of typhoid fever, it would not be possible to limit the duration of the disease to the first week (?), and if, at least, it would not be possible to obtain a number of cases belonging to the abortive form. Nevertheless, M. Caussidou does not conceal the dangers of salicylate medication. Like other observers, he has noted dyspnœa, precordial trouble, and exhaustion in patients where the salicylate of soda brought on a too sudden apyrexia. To avoid these objectionable results, he proposes to administer salicylate of soda in fractional doses of one gramme given every two hours, and to stop as soon as the temperature falls below 38° Cent. (100.4° Fahr.) In a complicated case of erysipelas, the salicylic medication was powerless to produce a febrile recrudescence brought on by this complication. M. Hérard declared that he had nothing but commendation for the use of antiseptics, such as carbolic and salicylic acids, in the treatment of febrile diseases.—*London Med. Record*, July 15, 1881.

Period of Latent Muscular Excitation in Different Nervous Diseases.

This paper (*Archives de Physiologie*, No. 2, 1880) is a continuation of MENDELSSOHN'S previous communication (*Travaux du Laboratoire de M. Marey*, 1880), in which he had given the results obtained by him in the physiological laboratory from experiments on frogs and healthy human subjects. The main conclusion which he had reached in the latter was, that the time of latent excitation is not constant, but varies even in the same subject, with variable conditions of nutrition, rest, amplitude of muscular curve, strength of exciting current, etc. In the frog it averages .008 second; in man, .007. Generally speaking, the duration of latent stimulation bears an inverse ratio to the muscular excitability and contractility. Experiments in diseased conditions bear out these physiological data. There is a diminution of the lost time in hemiplegic late rigidity, an increase in hemiplegic muscular atrophy, and so on in the whole list of diseases with tendency either to contracture or to atrophy. The author found considerable variations prevail in hysteria, but noted that shortly before an attack the lost time was shorter. In artificial catalepsy, it sunk to .001 second. [Waller (*Brain*, No. 10, 1880), in a recent paper, assumes the time of latent contraction of healthy human muscle to be .02 second, and gives tracings in support of his view. It will be remembered that Helmholtz (1852) had estimated the same period (in frogs) at .01 second, and that his determination has since been generally accepted and reproduced in text-books.—*Rep.*]—*London Med. Record*, June 15, 1881.

Spinal Myosis and Reflex Pupillary Rigidity.

Prof. W. ERB (*Centralb. für die Med. Wiss.*, No. 17, 1881) has found that, out of 84 cases of tabes dorsalis, 59 had absolute reflex pupillary rigidity, 12 showed very feeble and low reaction to light, and in 13 the reaction was normal.

In 5 cases the symptom was unilateral, in 7 there was more or less advanced atrophy of the optic nerve. Out of the 71 cases in which more or less rigidity was present, 37 had distinct myosis, 34 had normally wide pupils, sometimes unequal. Myosis was absent in quite half the cases. Of the 71 cases, 43 were in the initial stage; in the remaining 28 the ataxy was already manifest. These symptoms may therefore appear quite early in the disease, or, on the other hand, be absent after it has existed for years; a closer connection between syphilis and pupillary rigidity appears not to exist in tabes. Out of 16 cases of progressive cerebral paralysis, he found the pupils only twice normal; in 10 they were unequal, but of these only 3 showed rigidity; in 4 cases there was myosis combined with rigidity. All this holds good also of the earlier stages of the disease. Very much more often were pupillary differences observed, 10 times in 16 cases; the reflex rigidity, on the other hand, only 7 times (once unilaterally). This symptom was also noticed several times in other diseases (anæmia, syphilis, tumours); in myosis after disease of the cervical sympathetic, the reaction to light is generally preserved, as well as in lesions of the cervical part of the spinal cord. Myosis and rigidity do not appear to occur together in healthy persons; in uncomplicated senile myosis, the reaction to light is unaffected. They must, therefore, be regarded separately. Respecting the former, it is most probable that the pupil-dilating centre, or its tract in the spinal cord or in the cervical sympathetic, is paralyzed; the rigidity, on the other hand, seems to be due to some change in the reflex arc, which lies between the centres of the optic nerve and the third nerve. Further observations, by irritation of the peripheral cutaneous nerves, showed that not only was there paralysis of the reflex contraction of the pupil, but also of the reflex dilatation, so that the expression "reflex rigidity" is doubly correct.—*London Med. Record*, July 15, 1881.

—

Magnet, Statical Electricity, and the Tuning-Fork, in Pseudo-Syphilitic Paralysis.

Drs. Ch. Mauriac and R. Vigouroux (*Le Progrès Méd.*, 1881, No. 19, 21, and 22) have published two examples of what they describe as a rare form of nervous disorder occurring during the course of syphilis, but of which it is difficult to determine exactly what part syphilis plays in their determination. The first case was that of a man, a haircutter, aged 22, who had chancres, followed by roseola, crusts on the scalp, sore mouth, with headache, fever, and night-sweats. After treatment for two months he was discharged cured, but soon returned with a painful tumour over the inner aspect of the arm, along the inner border of the triceps; under large doses of iodide of potassium this rapidly disappeared, but the limb became anæsthetic, with loss of motor power, and preservation of normal electrical reactions. This did not improve under iodide; but the application of a magnet caused headache, and complete transfer of the anæsthesia and paralysis to the sound arm; repeated applications cured these for a time, but he relapsed after a few days. Statical electricity, repeated three times, produced no effect but slight numbness of the fingers and dorsum of the hand. By introducing the sound hand into the resounding box of a large tuning-fork (ut 3), transfer of the affection was effected, and at the same time there was produced hemianæsthesia of the sound side, with loss of taste, smell, hearing, diminution of the field of vision and visual acuity, and complete colour-blindness; in every respect this resembled hysterical hemianæsthesia. By the following day the phenomena had changed sides, even the artificially induced hemianæsthesia having become transferred. By repeated applications, a cure was effected: the patient went home, relapsed again, was put on iodide of potassium, and after taking it for some time,

got well suddenly, and has remained well. The second case was that of a man, aged 40, who denied all venereal antecedents, and the diagnosis of constitutional syphilis rested on the presence of a fissured and atrophied tongue. He had been epileptic when young, and his mother suffered from the same disorder. After suffering from diffuse superficial headache, worse at night, he became hemianæsthetic, the anæsthesia affecting the special senses, with some loss of power in the lower extremity. The magnet and tuning-fork caused malaise and insomnia, but had no influence on the neurosis. Statical electricity caused transfer, and cured him after twenty sittings of forty to forty-five minutes each. The authors admit that the evidence of syphilis was not clear, but the lesion of the tongue was regarded as syphilitic, both at the Hôtel-Dieu and at St. Louis. The phenomena were not those of ordinary syphilitic paralysis, yet a localised lesion in the posterior part of the internal capsule would be capable of giving rise to these symptoms. The early epileptiform attacks in the first case, and the existence of hystero-epilepsy in the mother of the second, indicate that in both there was a predisposition to nervous affections. The inefficacy of ordinary antisyphilitic remedies is opposed to the notion that these symptoms depended directly on syphilitic lesions; but syphilis probably played the part of an exciting cause.—*London Med. Record*, July 15, 1881.

—

The Cephalic Souffle in the Adult.

In 1838, Dr. Fisher, of Boston, published in the *American Journal of the Medical Sciences*, a paper in which he described the *bruit de souffle* in the head, and stated that he had met with this sound in auscultation of the cranium in cases of chronic hydrocephalus, cerebral congestion, either simple or coincident with dentition or whooping-cough, in acute encephalitis or meningitis, in suppuration of the brain, induration of that organ, etc. Other authors recognized the same sound later, and reported it with other affections; among others, M. Henri Roger, who found it only exceptionally after the closure of the fontanelles, and expressed the opinion that cranial auscultation is not really applicable to persons past the first two or three years of life. Subsequent writers to M. Roger have, as a rule, agreed with him in this opinion, though it has, perhaps, not been altogether denied that the cerebral *souffle* might occur in the adult also.

M. Raymond Tripier, in a memoir published in the *Revue de Médecine* (the continuation of the *Revue Mensuelle*), Nos. 2 and 3 of this year, takes up the subject anew and reports six cases of the occurrence of this intracranial *souffle* in the adult, with a very thorough discussion of the conditions of its occurrence and its significance. The following are the conclusions of his memoir:—

1. The cephalic *souffle* occurs in the adult as Fisher and Whitney have stated, and, contrary to the opinion of M. Henri Roger, now generally accepted.

2. I have met with it in one case of anæmia from neuralgia, in several cases of chlorosis, in one patient suffering from cachectic anæmia, in one case of intracranial tumour, and in a case of hydrocephalus.

3. It is a profound systolic *souffle* that can be heard over the whole cranium, but principally over the lateral portion at the horizon of the temples; its maximum intensity is in the right temporal region, and it does not appear to be modified by changes of position of the head and trunk.

4. The patients in whom it occurs have no intermittent sound synchronous with the *souffle* heard on auscultation, and, consequently, with the cardiac systole, the intensity of which is in direct relation with that of the cephalic *souffle*.

5. Both this subjective sound and the *souffle* may be modified or suppressed momentarily by the compression of the carotid on the side auscultated, or even that of the opposite side. Simultaneously we observe in the anæmic patients the

production of a general *malaise*, with numbness of the hand of the side opposite the compressed carotid. These phenomena are most marked, or are only produced by compression of the right carotid.

6. The cephalic *souffle* may be diminished or disappear with a cure or an aggravation of the disorder which it accompanies.

7. The cephalic *souffle*, being perfectly synchronous with the carotid systole, ought to have its origin in the arterial system. It is not due to a transmission of the systolic *souffle* of the heart that we observe in anæmic or chlorotic patients, nor to that of a *souffle* occurring in the arteries or veins in the neck. By exclusion, we locate it in the terminal portion of the internal carotid, at the point where it enters the cranial cavity. Not only are there many reasons militating in favour of this location, but in one case there was found a small tumour, situated alongside the artery at this horizon, which gave rise to a sound altogether similar to that found in the other cases. The *souffle* may be produced on both sides, or only on one side, and that, preferably, the right.

8. In anæmias due to hemorrhages or to cachexia, as well as in chlorosis, the cephalic *souffle* is met with when the symptoms of anæmia are especially intense and of long duration, notably when there is a very pronounced discoloration of the integuments, palpitations and breathlessness with the slightest exertion, digestive disturbances, and especially vomiting, together with great weakness.

9. In these cases there exists a cardiac systolic *souffle*, which is lacking in cases connected with an intracranial lesion.

10. A cephalic *souffle* without any corresponding sound at the base of the heart, and especially without coexisting anæmia, ought to suggest the possibility of compressions of the internal carotid in its terminal portion, when there is no disease of the orbit.

11. The cephalic *souffle* can be distinguished by the above condition from the continuous *souffle* with reinforcements, which may appear intermittent, produced by communication of the carotid with the cavernous sinus, as well as from the intermittent *souffle* due to aneurisms of the carotid and the ophthalmic arteries, since in both these cases there are characteristic symptoms on the part of the orbit.

12. We have not met with the cephalic *souffle* in the cerebral affections mentioned by Fisher and Whitney, with the exception of hydrocephalus.

13. We have also not found it in the healthy adult.

14. Is there a continuous cephalic *souffle*? We have not met with it in the adult. But the patients may hear sounds that are probably venous *bruits*, either continuous or intermittent, but which must not be confounded with those accompanying the cephalic *souffle*.

15. The cephalic *souffle* may afford important indications for the diagnosis, prognosis, and the treatment of the disease in which it occurs.

Parotitis as a Complication of Ovariotomy.

Dr. MÖRICKE, in a communication to the *Zeitschrift für Geburtshülfe und Gynäkologie*, narrates five cases in which inflammation of the parotid gland followed ovariotomy, and in four of them went on to suppuration. He refers to the well-known connection between inflammation of the testis and of the parotid gland, and quotes cases from other authors in which affections of the female genitals—swelling of the labia, vulvo-vaginal catarrh, swelling and pain in the breasts, swelling and pain of the ovary—came on in the course of mumps. He thinks these instances point to a connection between the parotid gland and the ovary, similar to that which exists between the parotid gland and the testicle. In sup-

port of this view he further states that he has never seen parotitis follow any other operation on the female genitals, although the operations of this kind which he has done far exceed in number his ovariotomies. In one of his cases there was the possible source of fallacy, that some children suffering from mumps were in the hospital at the time, and a nurse caught the disease. But the ovariotomy case was kept separate from the other patients, had her special nurse, and no other patients in the hospital caught the disease. The criticism, that parotitis is not uncommon in the course of the acute infectious diseases (typhus, scarlatina, etc.), and in pyæmia, he anticipates by saying that his patients were not suffering from any of these diseases; nor was the inflammation so acute or so dangerous as in the pyæmic form. In time of occurrence and in frequency it closely resembled the orchitis which complicates mumps. The parotitis came on five times out of 200 cases of ovariotomy, and began from the third to the seventh day after the operation. Orchitis in mumps is said to occur once in sixty cases, and to come on, as a rule, about the sixth day.—*Med. Times and Gazette*, Sept. 3, 1881.

—

Peripheral Temperatures in Lung Diseases.

ANREP has made a series of observations on fifty cases of lung disease, with a specially constructed thermometer, which may be described as an ordinary clinical thermometer in which the bulb has been flattened out horizontally, and is protected from draughts by a glass bell springing from the sides of the tube below the index. With two such instruments accurately compared beforehand, he observed (*Verhandl. der Physik. Med. Gesellsch. in Würszburg*, Band. xiv. Heft 1, 2) the temperature on opposite sides of the thorax of healthy individuals. He found the average to be about 96.3 deg. Fahr.; but the temperatures were very rarely the same, the difference varying from 0.2 deg. Fahr. to 0.5 deg. Fahr., sometimes on the one side, sometimes on the other. The cases of lung disease observed were pleurisy, croupous pneumonia, and chronic catarrhal pneumonia. In pleurisy the cutaneous temperature of the affected side (thermometer in an intercostal space) is higher than the axillary temperature of the opposite side, and the highest temperature corresponds to the time of most rapid effusion. The cutaneous temperature of the opposite side is also slightly raised. In pleurisy without effusion, the rise of cutaneous temperature is neither so great nor so long continued. In cases of croupous pneumonia, the difference between the two sides amounted to as much as 2.7 deg. Fahr.; and from the tables given by Dr. Anrep it can be seen that those parts of the lung in the first stage of inflammation, before crepitation has appeared, give a higher temperature than those completely solidified. In chronic catarrhal pneumonia, the cutaneous temperatures closely agree with the local progress of the disease; and in one case fully recorded the rapid rise of temperature over the apex, followed by a fall as the symptoms of a large cavern developed themselves, is very striking, more especially as the temperature over the cavern continued lower than all the rest of the chest. The author believes that the observation of cutaneous temperatures is, even at the present, of practical value; and when the clinical thermometers now in use are replaced by thermomultipliers, we shall be able to derive from it most valuable information.—*London Med. Record*, July 15, 1881.

—

Typhoid Pleurisy.

In certain very rare cases, acute pleurisy may take on a typhoid form which is extremely serious, and almost always ends fatally. Dr. A. GOUMY, who has studied this disease very carefully, thus summarizes in his inaugural thesis the

indications for treatment (*Revue de Thérap.*, p. 331). To keep up the general condition of the patient by hygienic measures, tonics, in large doses, given at an early stage, are the most urgent indication. Subsequently, the pleural liquid must be evacuated as early as possible. One puncture is made, then a second, and if the general condition do not improve, pleurotomy is resorted to. Professor Bouchard is greatly in favour of this treatment; two out of three cases, under his care, recovered under this treatment. The incision of the thoracic wall disengages the lung, and favours its gradual and progressive expansion. Antiseptic washings-out prevent any danger of putrid infection; for this purpose carbolic acid, sulphate of zinc, a three per cent. solution of salicylic acid which has been employed by Potain, and a five per thousand of chloral which has been employed by Villemin, are all recommended. According to the recent statistics compiled by Robert, pleurotomy has yielded 78 cures out of 114 cases. These figures are satisfactory, especially if the frequency of symptomatic pleurisy be taken into account.—*London Med. Record*, Aug. 15, 1881.

—

Favourable Influence of Hydro-Pneumothorax upon the Progress of Pulmonary Tuberculization.

This paper (read at the meeting of the French Association for the Advancement of Science at Algiers by Dr. HÉRARD, Physician of the Hôtel-Dieu) was intended to show that, whereas ordinarily the occurrence of hydro-pneumothorax in the course of phthisis forms a serious and often fatal complication, in a certain number of cases, more frequently than is supposed, it exercises a favourable influence on the progress of the malady, may arrest its progress, and become an unhoped for means of safety to the patient. Dr. Hérard had collected a certain number of observations, which established in the clearest and most positive manner this salutary influence of hydro-pneumothorax. An illustrative case was that of a youth, a mechanic, aged 17, who was admitted into the Hôtel-Dieu on July 15, 1880. His mother died of chest-disease, and his father from tuberculosis. He had been delicate from childhood, and had suppuration of the right ear since three or four years of age. Since a sudden chill in May he had had a constant cough, with expectoration, which became muco-purulent. Loss of strength and appetite, sweating, and profuse diarrhœa followed. These symptoms, together with great emaciation and hectic fever, were present on his admission.

Auscultation showed the existence of blowing respiration and subcrepitant *râles* at the right apex. Over the left apex there were cavernous breath-sound and gurgling, especially marked behind. There was dulness on percussion over the left apex, and some loss of resonance over the right. The vesicular murmur over the rest of both lungs was nearly normal. On August 10, on making a hasty movement, he was suddenly seized with an acute pain in the left side, and with intense dyspnœa; his face was pale and anxious. Tympanitic resonance was found all over the left side, except for about four or five finger-breadths at the base, where there was marked dulness. Amphoric voice and breath-sounds with metallic tinkling were heard on auscultation, the thoracic vibrations were abolished, and succussion could be easily felt, even by the patient himself.

For some days the patient was alarmingly worse; the lower limbs became œdematous, and the evacuations were involuntary; he was thought to be on the point of death; but, after a struggle of several weeks, about the end of September, a favourable change took place, and from that moment he continued to mend daily. The dyspnœa diminished; strength, appetite, and sleep returned. The cough diminished; and the expectoration, before so abundant, almost completely disappeared. The physical signs at that time were dulness, and resistance to the

finger at the left base behind, exaggerated resonance in the other parts of the chest; the amphoric breath-sound and the metallic tinkling had disappeared, but succussion was still perceptible; the cavernous blowing and the subcrepitant *râles* had notably diminished. The heart remained displaced to the right. At the end of November he was able to return to his home in the country. Had he been able to pass the winter in a favourable climate, Dr. Hérard believes he might have been completely restored to health. Such cases as these are not rare or isolated ones; twenty such are collected in the thesis of Dr. Toussaint, from different authors.

How shall we explain the favourable influence of hydro-pneumothorax in these instances, and what is the mechanism by which a cure is effected? Is it possible to foresee in what cases such an issue may be hoped for, and in what cases a fatal event may be anticipated? Bearing in mind the anatomico-pathological conditions under which hydro-pneumothorax may occur, we may arrange the cases under three categories, founded on the state of the tuberculous lung.

In the first category, the lesions of the lung are in their earliest stage. The lung presents scattered granulations or small caseous nodules, in the midst of a tissue more or less hyperæmic, but in a condition in which any sudden compression might reduce it to a small volume. The occurrence of hydrothorax in such cases is not rare. All that is necessary in order to establish a communication between the bronchi and the serous cavity, is the softening of one of these small tuberculous masses on the surface of the lung. The first effect of such an accident is the compression and flattening of the lung by the escaped air and the liquid effusion which rapidly follows. Later on, false membranes envelop the organ in a sort of thick resistent shell, and maintain it reduced often to quite an insignificant volume against the vertebral column and groove. The lung, under these circumstances, is dense and carnified, and its functional activity is greatly diminished or completely suppressed; we can readily understand how, in such a case, the tuberculous evolution is checked, or sometimes altogether arrested.

In the second category the pulmonary lesions are much more advanced, and the phthisis has reached the second or third stage only, and this is the important point; these changes are limited to the upper lobe, the other lobes presenting merely granulations or small caseous masses, surrounded by more or less congested lung-tissue. As in the first category, the effect of hydro-pneumothorax, by compressing the lung, is to arrest its functions, and in diminishing the afflux of blood, to prevent the nutrition of the morbid products, and to stop, in short, the tuberculous process. At the same time another remarkable phenomenon takes place in the upper lobe; the walls of the cavities, yielding to compression, come together, become agglutinated, and sometimes even cicatrize; the pulmonary suppurations and excessive bronchial secretion diminish, and, as in the case cited, the expectoration is completely suppresed. This suppurative process being arrested, the consequent hectic fever, sweating, diarrhœa, etc., disappear also, and the patient passes from the most alarming state into one of sensible amelioration, and even of real cure. But to insure so favourable a result, it is necessary that the opposite lung should be and remain free from disease.

One of the cases cited by Dr. Toussaint gives anatomical demonstration of the cicatrization of cavities under such conditions. A young soldier presented all the signs of pulmonary tuberculosis in the third stage, gurgling, loud cavernous blowing, metallic bruits at the left apex, and a few subcrepitant *râles* at the right apex; abundant purulent expectoration, great emaciation, profuse sweatings, hectic fever, intractable dyspepsia. A few days after admission into hospital, a sudden access of suffocation, with pain in the left side, drew attention to the occurrence of hydro-pneumothorax. For some days the patient seemed on the

point of death, when slowly and unexpectedly he began to revive; the dyspnœa abated, the fever disappeared, and the appetite became good. The sweatings ceased, and the expectorations changed completely in character, and became scanty and glairy. This amelioration was maintained and augmented until some months afterwards, when an exudation into the right pleural cavity gradually increased, in spite of all that could be done, and the patient died. The necropsy showed the existence of double pleural effusion. The left lung was flattened and compressed upwards and backwards, and strongly bound down, so that it did not reach below the fourth rib; at its apex there were traces of a large cavity, the walls of which were in contact and had become agglutinated and cicatrized; it was represented by a gray, irregular band, about the size of the little finger. Two smaller bands indicated the existence of two other smaller cavities. These were surrounded by masses of hard cretaceous tubercle. The right lung presented at its apex a few small masses of hard tubercle. These observations show the important part which the compressibility of the pulmonary tissue takes in the cure of such cases.

In the third category we find the whole of the lung invaded by tuberculous lesions (granulations and broncho-pneumonia); the organ is hard, compact, resistant, irreducible by compression; in such cases, hydro-pneumothorax can only increase the peril which already exists.

It is incorrect, then, to regard the occurrence of hydro-pneumothorax in the course of phthisis as always fatal; on the contrary, in certain well characterized cases, it may be of favourable import.—*London Med. Record*, Aug. 15, 1881.

—

Heart Symptoms of Chorea.

Dr. Octavius Sturges, Physician to the Westminster Hospital, London, publishes in *Brain*, July, 1881, an interesting paper, in which he shows that in chorea the heart is apt to sympathize with the voluntary muscles at all ages up to the adult period, this sympathy being shown as well by dynamic murmur as by accelerated action, unevenness of rhythm, and, not seldom, the excited impulse common in hysteria, the particular manner of response being dependent upon the age of the patient. The hypothesis is that these several modes of heart affection correspond with as many modifications of chorea, which are exhibited not in the heart only, but in the voluntary muscles as well; these several regions sharing jointly, each in its own degree and after its own manner, in a disorder the area of whose influence is coextensive with that of ordinary emotional disturbance; and particularly that in all such variations the motor element of the affection is represented mainly by irregularity and unevenness of cardiac rhythm, the emotion element by acceleration, and the paresis element by dynamic murmur.

—

Treatment of Cardiac Diseases.

According to Prof. Renzi, bromide of potassium diminishes the anxiety of patients with heart disease, and renders their respiration easier. Under its influence sleep is more tranquil, easier, and lasts longer. The number of cardiac pulsations and respiratory movements diminishes; the cough, however, seems to be aggravated by this remedy. Iodide of potassium succeeds better, particularly in ameliorating the respiratory symptoms and in overcoming dyspnœa. Hydrate of chloral serves to overcome the insomnia in cases of heart disease, but in general it does not diminish dyspnœa of cardiac origin. It tends, moreover, to increase cerebral torpor and somnolence, and when combined with iodide of potassium it tends to produce a serious and persistent somnolence.—*Journ. de Méd. de Paris*, Sept. 10, 1881.

A Case of Prolonged Intestinal Obstruction.

Dr. F. W. DRAPER, of Boston, reports the following case. The patient was a man, aged thirty-three, of sedentary habits. For six years, dating from an attack of "inflammation of the bowels," he had been subject to recurrent attacks of obstinate constipation, in one instance lasting ten days, and accumulation of flatus. On June 28, 1880, after indulgence in iced water, he was attacked with slight vomiting, distension of the abdomen, and moderate pain. The matter vomited was of a bilious character. The abdomen was uniformly distended and tympanitic, without tenderness, and careful palpation and percussion detected no region presenting exceptional signs. After the second day vomiting ceased spontaneously; there was obstinate constipation, which lasted for twenty-one days, in spite of the employment of laxatives, turpentine stupes to the abdomen, and stimulating enemata. Sulphate of magnesia was once employed, but increased the patient's misery; belladonna was employed until its physiological effects gave warning to desist. The intestines were four times aspirated, and large quantities of gas removed; large enemata of warm water were also employed without effect. On the twenty-first day flatus escaped from the anus, followed by scybalous fæces, and on the next morning a normal stool was voided; and for nine days, though weak, the patient appeared to be in good health and spirits. On the ninth his symptoms returned, but with increased severity, and death occurred seventy-two hours after the onset of the attack.

An autopsy was made thirty-two hours after death: The abdominal walls were distended to the utmost; when the usual longitudinal section was made, the intestines escaped through the incision in huge convolutions. The entire length of the small intestine and the ascending and transverse portions of the colon were fully loaded with mingled liquid and gaseous contents. The peritoneum was everywhere injected, and the vessels of the omentum were especially engorged. In the dependent portions of the abdomen there was an effusion of dark-red, thin fluid, amounting, by estimate, to eight fluidounces. The colour of the small intestine was a dark purple; its diameter was that of a large orange; its contents consisted of dark-brown, fetid liquid feces. The distended large intestine was of a pale colour; its diameter was six inches and its contents semi-solid fæces. Search was made for the points of puncture by the aspirator needle, but no remnant of that operation was found. There was no agglutination of the intestinal folds or other indication of peritonitis, beyond the intense general hyperæmia and the fluid exudation.

At the junction of the transverse and descending portions of the colon (splenic flexure) there was a cicatricial constriction. In the concavity of this flexure the three coats of the intestine were drawn into a firm, dense mass of tissue, the puckered folds of which contraction had reduced the calibre of the gut so as scarcely to admit the tip of the little finger. Above this stenosis the intestine was dilated into a great bag or reservoir filled with semi-solid fæces; below it the gut was contracted to its normal dimensions. Seen from within the intestine showed nothing remarkable at the constriction beyond the puckering of the mucous lining; on the outside (peritoneal surface), however, the stenosis was marked by a roughened, elevated ulceration of the size of a silver quarter-dollar. A fold of the jejunum was attached by loose adhesion of its free border to this ulcer, and its peritoneal coat presented a corresponding, though more superficial, loss of tissue. The situation and relations of the constriction were such that it could easily be plugged by a fæcal mass of slight consistency.

Upon the surface of the large intestine, just above the ulceration, was a minute perforation which hardly admitted the head of a probe, and through this small

opening enough fæcal matter had probably escaped to develop the peritonitis which destroyed the patient.—*Boston Med. and Surg. Journ.*, Sept. 22, 1881.

—

Amyloid Degeneration of the Kidney.

In the twenty-eighth volume of the *Deutsches Archives für Klinische Medicin*, WAGNER publishes an interesting paper upon amyloid degeneration of the kidney. In regard to etiology, out of 265 cases, Wagner found that 136 accompanied phthisis; 56 occurred along with disease of bone (non-syphilitic); 36 accompanied syphilis; 30 were found in connection with certain rarer diseases; and with regard to 7 no probable mode of origin was apparent. The more interesting portion of this paper is that in which the author deals with the symptomatology of waxy kidney. In comparatively few of these cases were the symptoms observed during life so closely as to be of service; only twenty-four appear to have been available, and of these the majority were only under observation for very limited periods; the longest apparently only during a few months. Studying these cases in detail, Wagner separates them into four groups: 1. Slight amyloid degeneration of the cortical or the medullary substance, or of both, without alteration of the epithelium or of the stroma; this variety was hardly observed clinically; 2. Greater or less waxy degeneration of the cortical or medullary portion, with a varying amount of fatty degeneration of the epithelium, without changes in the stroma; 3. The same waxy degeneration, along with fresh interstitial changes; 4. Waxy-contracted kidney. In regard to this last-named condition, Wagner adopts the view held by Cohnheim, Bartels, Rokitansky, etc., viz., that the waxy change occurs in the kidney after it has become cirrhotic. With regard to the condition of the urine in these cases, Wagner found that it was almost invariably diminished in quantity, and this without diarrhœa, perspiration, or increasing œdema being present. In a few cases the urine was of normal quantity, and only in two does it appear to have exceeded that amount. The quantity of albumen was in thirteen cases of the fifteen belonging to the first two groups, in medium or in great amount ($\frac{1}{4}$, $\frac{1}{2}$, $\frac{1}{3}$, or even 1 volume); but in two cases it was at the commencement small in quantity, afterwards increasing. The tube-casts varied much in number from one day to another. They were for the most part of medium diameter, and usually hyaline, sometimes fatty. Wagner believes that œdema is more rarely met with in such cases than is generally supposed. In conclusion he observes that, while waxy kidney may often be diagnosed with care, there are many cases in which such a diagnosis cannot be arrived at with any certainty.—*Lond. Med. Record*, July 15, 1881.

—

The Pathogenesis of Albuminuria.

The physiological experiments of Gull and Stokvis, of raising the arterial pressure in the kidneys by ligaturing arteries or compressing the abdominal aorta, showed that high pressure alone would not determine albuminuria. This may seem at variance with the clinical fact of the presence of albuminuria in interstitial nephritis with hypertrophied heart; but M. CHARCOT, in a recent lecture (*Le Progrès Médical*, 1881, No. 19), explains this by the fact that some of the glomeruli are more or less profoundly altered, in consequence of which both the pressure and the rapidity of the blood-current are diminished. [It is obvious that, if the changes in the glomeruli are to be called in question at all, M. Charcot is departing from the mechanical theory he has propounded.—*Rep.*] On the other hand, Overbeck's experiment of reducing the blood-pressure by introducing a sound into the right ventricle, carrying a small bladder which can be inflated at will, is always followed by albuminuria. Here the condition of things is dimi-

nution of pressure and rapidity. Such a condition is met with clinically in valvular disease of the heart, chronic disease of the myocardium, and some pulmonary diseases. In cases of mitral insufficiency, Rosenstein observed that the albumen disappeared as the urine increased, and returned as it fell in quantity. The cardiac kidney is not the cause of the albuminuria of heart disease, but the consequence of the state of things which causes the albuminuria. The albuminuria of Asiatic cholera and other acute diseases is also explained by this theory. The anatomical theory which refers albuminuria to a lesion of the renal epithelium, supported of late by Lécorché, is opposed by the experiments which show that albumen is excreted by the glomeruli, and that its presence in the convoluted tubules is a pathological occurrence, and by the fact that the epithelium may be profoundly altered or destroyed, as in granular kidney or in phosphorus poisoning, without albuminuria.—*Lond. Med. Record*, July 15, 1881.

—

Simultaneous Existence of Albumen and Sugar in the Urine.

In a paper read before the Berlin Medical Society, and published in the *Deutsche Med. Woch.*, No. 24, 1881, Professor Frerichs says that the coexistence of albumen and sugar in the urine occurs under various conditions, which must be carefully discriminated. Three forms of this anomalous process of secretion must be distinguished: one occurring in glycosuria, another in diabetes mellitus, and a third in chyluria. In glycosuria—by which Frerichs denotes cases in which small quantities of sugar are discharged within a longer or shorter time without having any obvious influence on nutrition—albuminuria is frequently met with. Of thirty cases observed and collated by Frerichs, albumen was found in fourteen, that is, in nearly one-half. They were partly acute, partly chronic, diseases of the brain. Three times albumen and sugar were observed in the urine of patients affected with cerebral aneurism, which had burst into the ventricles; four times in extensive apoplexies; twice in purulent cerebral meningitis; and once in chronic tuberculous basilar meningitis. In all these cases the ventricle was found to contain blood, with the exception of one case, in which the apoplectic focus extended to part of the cerebellum and to the cerebral peduncle. The chronic form of the disease lasted for years, and there was no opportunity of making a *post-mortem* examination. In these cases Frerichs three times observed albuminuria, and also, in the further progress of the disease, simultaneous paresis of the facial nerve. The sugar in these cases amounted to from 1½ to 2 per cent., while the quantity of albumen varied. Sometimes the sugar disappeared, and then the albumen, until in some cases there was a retrogression of the renal secretion. At the same time polyuria existed; in other cases it was absent.

In all these cases of glycosuria, Frerichs thinks the secretion of albumen and sugar to have the same source, namely, a lesion of the fourth ventricle, since, when the injury is situated higher, there is secretion, not only of sugar, but of albumen also. In such cases, the prognosis must depend upon the nature of the cerebral lesion. Severe apoplexy, with lesion of the lateral ventricle, usually proves fatal in a few days; so also does cerebral aneurism. The course is more favourable in meningitis, in which recovery occurs in some circumstances. Frerichs reports two cases, in which the secretion of albumen and sugar ceased, and all symptoms disappeared.

In the chronic form, the prognosis must be cautiously made, for this mostly affects persons whose health is impaired by mental excitement or overwork, who complain of headache and indisposition, and are unable to attend to their daily avocations. Apoplectic injuries are associated with remarkable frequency with

glycosuria, a circumstance that points to an effusion of blood into the fourth ventricle.

In the same manner may be explained the coexistence of albumen and sugar in cases of poisoning, especially by carbonic oxide gas. In 12 out of 17 cases there was sugar; in three there were albumen and sugar; and in one only albumen, together with cylinders.

In diabetes mellitus, the condition is altogether different. It is assumed by many that diabetes mellitus will lead to nephritis. Griesinger, in 64 *post-mortem* examinations of cases of diabetes, found 32, that is, one-half, complicated with nephritis. Seegen found nephritis in 20 of 30 cases in the Vienna *post-mortem* house; while Dickinson found 25 of 27 cases in the St. George's Hospital to have nephritis. With that, however, Frerichs's experience does not agree. In true diabetes, albuminuria is not frequent, nephritis rare, and occurs only in certain conditions. Out of 316 cases of diabetes mellitus, which Frerichs partly observed for ten, twelve, and even fifteen and sixteen years, there were only 16 cases of nephritis (5 per cent.). Cases in which small quantities of albumen were occasionally found in the urine were never pure and simple cases, since it could be proved, at least in most of them, that other processes were involved, which of themselves could produce nephritis. Of 16 cases, 6 were complicated with arterial sclerosis; in 3 others there was pulmonary phthisis; in 2 cystitis; and in 2 arthritis with renal calculi. Therefore, only three cases remain in which no co-operating cause could be suggested. Thus it becomes evident that the general belief that the increased action of the kidneys in diabetes mellitus leads by fluxion to albuminuria and nephritis is erroneous, notwithstanding that it has numerous followers. According to Frerichs's *post-mortem* examinations, which comprise more than 50 cases, true nephritis is hardly ever met with in diabetes; and where it did occur, it was of a parenchymatous nature, moderate hyperæmia of the renal substance, or there was shrivelling of the kidney. It has been believed that the changes of the epithelium of the gland, now and then occurring in diabetes, and lately described by Ebstein, might contribute towards the production of albuminuria. These changes in the epithelium have been searched for in the clinic, and have been found where there was no albumen in the urine; so that Frerichs feels rather disinclined to go as far as Ebstein does in drawing conclusions. All cases which were complicated by pulmonary phthisis proved fatal, while in all cases in which albuminuria was produced by additional cystitis, nephritis, or arthritis, there was a favourable course. An old gentleman, aged 79, who was attacked with pneumonia while in Carlsbad, and was afterwards lying ill in Nice, suffered from albuminuria, on which cystitis supervened. Gradually the sugar disappeared, and albuminuria, with cylinders, set in. Then the albumen disappeared, and at present he may be regarded as cured.

There is yet another condition in which sugar, albumen, and fat occur together—chyluria. It remains, however, an open question how the sugar is transmitted into the urine along with the albuminates. Whether, as some believe, there is a damming back into the lymphatic vessels or a transition into the urine, consecutive upon chylosis, has not yet been determined by anatomical observation. One thing only has been established by Brieger—that fat disappears from the urine, if it be withdrawn from the patient's food, and that it reappears in the urine as soon as it again becomes part of the food. It is much to be regretted that the experiment was not made with regard to sugar.—*London Med. Record*, August 15, 1881.

Urinary Analysis.

A new method for the quantitative analysis of the extractive matters of urine has been worked out by MM. CHAVANE and RICHET, who claim for it the advantage of much greater simplicity than that of the methods at present in use. A solution of biniodide of mercury and iodide of potassium, to which potash has been added, is blackened by urine, and oxide of mercury is precipitated. The reaction takes place even in the cold, but is facilitated by heat. Neither the urea, chlorides, phosphates, nor sulphates are precipitated, but uric acid causes a white deposit from which heat causes oxide of mercury to separate. Alkaloids, formiates, and acetates have no influence. If the reaction of the mixture is acid the precipitate does not form, a soluble salt of mercury being produced, but the alkalinity of the test solution is usually sufficient to insure the reaction. Salts of ammonia, moreover, mask the reaction by dissolving the oxide of mercury. Chloral, aldehyde, sugar, and all readily oxidizable substances also precipitate the oxide of mercury. Normal urine contains substances which have the same action, viz., nitrogenous substances soluble in ether and in alcohol. Hence this method gives a simple means of ascertaining the amount of colouring matter, extractive matter, and nitrogenous substances other than urea. The exact mode of proceeding is as follows: The composition of the solution is 10 grammes of binoxide of mercury, 20 of iodide of potassium, 50 of caustic potash, and 930 of distilled water. One burette is filled with the solution, another with urine. Fifteen drops of each are allowed to fall into a porcelain capsule, and it is heated and urine added until the mercury is proved to be precipitated by the absence of the reaction given by an alkaline solution of tin, with a small quantity taken up by a capillary tube. A litre of normal urine precipitates about five grammes of mercury.—*Lancet*, Sept. 24, 1881.

Surgery.

Antiseptic Treatment of Abscess.

Dr. LUCAS-CHAMPIONNIÈRE recommends the following procedure: Before opening an abscess, in whatever region it may be placed, we should carefully wash the skin, especially if it has been covered by a poultice, with a strong carbolic acid solution (crystals 50 parts, glycerine 50 to 75 parts, and water 1000 parts). The bistoury should also be dipped in the solution. The contents of the abscess are to be discharged, and some of the above solution injected, care being taken that the injected liquid has a free issue. The end of a caoutchouc tube is introduced into the wound, having a thread attached to it to facilitate its removal, and it is then covered by a thick layer of charpie, impregnated with a solution of carbolic acid 25 parts, glycerine 25 parts, and water 1000 parts. Finally, over all is laid a layer of gummed silk. At the end of twenty-four hours the tube is removed in order that it may be cleansed and shortened, when it is again covered with the charpie moistened with the weaker solution. Under this treatment the amount of suppuration is diminished, the redness of the wound becomes insignificant, and the cicatrices which result are much less apparent. Dr. Lucas recommends this procedure especially in abscess of the breast. — *Med. Times and Gazette*, October 8, 1881, from *Union Médicale*, September 15.

Treatment of Malignant Lymphosarcoma with Arsenic.

Dr. F. THOLEN (*Arch. für Klin. Chir.*, Band xvii.) reports four cases of lymphosarcoma, in three of which the course of the disease was greatly influenced

by arsenic, while in the fourth case the disease had already advanced too far towards a fatal result. The first case was that of a man, aged 47, who suffered from an infiltrated epithelioma in the right angle of his lower jaw, of three months' duration. It could not be operated upon, because of the extent and infiltration of the neighbouring lymphatic glands, and was therefore treated with arsenic. From May 26 until the end of December, 1872, the patient took Fowler's solution; partly internally, from five drops a day to fifteen drops twice a day, and partly in the form of parenchymatous injections into the tumour, ten drops each time, amounting altogether to 748 drops internally and 76 injections. This treatment resulted in the complete disappearance of the tumour. The patient was discharged on Jannary 15, 1873, and on returning in April, 1873, and in February, 1874, he showed no sign of recurrence. Examination of a small particle taken from the margin of the ulcerating tumour indicated a lamellar epithelioma, yet the appearance of the disease, as well as the favourable action of the arsenic, rather suggested an infiltrated malignant lymphosarcoma. The author, therefore, thinks it probable that epidermic cells from the adjacent healthy epidermis might have been present when the examination was made. From these cases, although few in number, Tholen is led to ascribe to arsenic a positive salutary action against cancerous ulcers, especially lymphosarcomata, which, in fact, are nearest to inflammatory neoplasms, and are quickly dispersed by other agents as well. A mischievous result has been several times observed by Billroth to follow this rapid breaking up, when iodide of potassium was energetically administered. —*London Med. Record*, August 15, 1881.

—

Treatment of Burns by Bicarbonate of Soda.

J. Troizki adds his testimony to that already published as to the value of solution of bicarbonate of soda as a dressing for burns (*Wratsch.*, 1881, No. 4; and *St. Petersburg Med. Woch.*, 1881, No. 19). He says that during the previous year he noticed twenty-five cases of burns, mostly of a severe nature. Sixteen of them were received in a fire in a village, during a strong wind, when the inhabitants, in order to save their property, were obliged to work in the flames. In all these twenty-five cases bicarbonate of soda was exclusively applied. The result of this treatment was so favourable, that the author considers himself justified in pronouncing this remedy the best and most efficient in burns of all kinds and degrees. Even in extensive burns of the second and third degrees, the pain was soon alleviated by the application of compresses soaked in a solution of bicarbonate of soda; and the wounds soon healed, leaving but few scars, and no impairment of the functions of the affected parts. No evil results from this extensive application of bicarbonate of soda, which might suggest the reception of carbonic acid into the blood, were noticed. Of the ten cases of which a detailed account is given by the author, one rather serious case may be related, in which the burns had spread over half the body. The whole face was stripped of epidermis, the hair was singed off, and the front of the neck, chest, and abdomen, and the dorsum of the foot, presented burns of the second degree; burns of the third degree were also found on the right mammary gland and on the right forearm, all the muscles of which were exposed as if prepared by dissection. A solution of the bicarbonate of soda was applied to these burns with a most conspicuous success: the patient felt relieved, and a cure was effected in four weeks; but the healing of the burns on the right breast and on the forearm lasted two months. The scars which were left were insignificant, and the mobility of the fingers was nearly normal. As regards the application of bicarbonate of soda in burns, the author distinguishes three methods. 1. Powdered

bicarbonate of soda is strewn over the burned parts. 2. Linen rags, sprinkled with a solution of bicarbonate of soda (1 in 50) are laid on; as soon as these rags become dry, they are replaced by others or are moistened again in the solution. 3. Linen rags are applied in the same manner, but are kept constantly upon the burns, and moistened by pouring the solution on them. The first method suffices only for burns of the first degree. Change of the moistened rags is chiefly adapted for burns of the third degree, attended with much suppuration. In exchanging the dry rags, the pus which has accumulated underneath them must be carefully washed off, that it may not be received into the blood; and then a fresh rag soaked with the solution must be placed upon the clean granulating surface. The third method is applied solely in burns of the second degree. Changing the compresses would in these cases only irritate the exposed surface, and, by causing a more copious suppuration, delay the healing process. The beneficent effect upon burns of the solution of bicarbonate of soda the author considers to be due to the anæsthetic, antiseptic, and disinfecting property, which the bicarbonate owes to the ready disengagement of carbonic acid from it. Herr Troizki has also made experiments with other antiseptic and disinfectant agents, but has come to the conclusion that these are inferior to the bicarbonate of soda in their effect upon burns. Besides, the application of some of these, as for instance of carbolic acid upon large surfaces, would be dangerous; on small surfaces they very thoroughly disinfect the secretions of wounds; but these disperse more slowly than by the use of soda, and the anæsthesia, so desirable for the patient, is not so complete as when soda is applied.—*London Med. Record*, Aug. 15, 1881.

—

Case of Coin in Air-passages treated by Inversion of the Patient.

Mr. JOSEPH BELL, Surgeon to the Royal Infirmary, Edinburgh, reports (*Edinburgh Med. Journ.*, June, 1881) the case of a waiter who amused himself by throwing into the air a sixpenny-piece just received from a traveller. He intended to catch it in his mouth, but the coin disappeared. Fancying it had passed into his œsophagus, he came to the Infirmary, where he was seen by the house-surgeon, Mr. Ross, who failed to find any evidence of its presence in either œsophagus or stomach, for the examination of the throat caused vomiting, and the coin was not found. No laryngeal or pulmonary symptoms were present, though patient pointed to his left chest as being painful. A laryngoscopic examination, however, satisfied Mr. Ross and Dr. Maxwell that the coin was lying edgeways in the left bronchus, just at the bifurcation. There being no symptoms, he was left quiet, all preparations being made for tracheotomy if necessary, and Mr. Ross slept in the side-room of the ward.

Next day Mr. Bell carefully examined chest and air-passages, with negative results; immediately after this, however, when he was in the act of operating on a sarcoma in the theatre, the patient was reported to be choking. Mr. Ross found him in a paroxysm of coughing, and when it passed off he described a feeling of fluttering or flapping in his windpipe. Dr. Wyllie and Mr. Bell then made a most careful laryngoscopic examination, and though they saw the tracheal rings most clearly, no foreign body could be made out.

The history and the symptoms of the one attack were to Mr. Bell's mind so convincing that the coin was in the air-passages, that, with the approval of his colleague, Mr. Duncan, he at once prepared to perform tracheotomy in the event of the failure of inversion. So, having obtained the patient's leave, and all things being ready, he was held by the heels by two dressers standing on the operating-table, and a smart blow was struck on his back opposite the left bronchus, while he was instructed to keep his mouth open and to breathe freely. The

sixpence at once fell into his mouth; a pretty smart cough coincided with its passing the glottis.

Cases of this kind are comparatively rare, and this one is an encouragement to attempt the inversion method. The surgeon must, however, be prepared to perform tracheotomy at once if the coin sticks in larynx and excites spasm, or lodges flatwise in upper part of trachea, and thus prevents ingress of air.

Gastrotomy in Stricture of the Œsophagus.

A paper by Dr. T. F. PREWITT on gastrostomy in stricture of the œsophagus will be found in the *St. Louis Cour. of Med.* It is accompanied by a table of fifty-nine cases. Dr. Prewitt considers the great difference in mortality from the operation in cases of this class, when compared with the same operation for the removal of foreign bodies, to be due to the exhausted condition of the subject. It is his belief that it can be greatly lessened if the operation be performed early. In a large percentage of fatal cases, even though union had taken place, no peritonitis existed, and death was due to exhaustion. Gastric fistula is not incompatible with long life. Of the forty-nine cases tabulated, forty were malignant, twelve cicatricial, three syphilitic, and in four the nature of the stricture was not given, but was almost certainly malignant. Of these cases, operated upon for malignant disease, the patients lived from fourteen days to six months, and one patient is still living comfortably. In the cicatricial variety six recovered, as also one where the stricture was of syphilitic origin. In but seven of the whole number is peritonitis stated to have existed. Exhaustion alone is assigned as the cause of death in the large proportion of cases.—*London Med. Record*, July 15, 1881.

Perineal Calculi.

Dr. C. MAZZONI, Professor of Clinical Surgery at Rome, read a paper on this subject at the London Congress which contained the following conclusions:—

1. Perineal calculi may originate in the bladder.
2. They may be formed in perineal fistulæ communicating either with the bladder or ureter.
3. They may be contained in a cyst formed by the walls of the ureter.
4. They may be found in the scrotum, and have no connection at all with the ureter.

Treatment.—In such conditions as are included under headings 1, 2, and 4, extraction of the stone results in a cure of the fistula. For those of class 3 it is imperative to make a permanent perineal opening into the urethra.

Midwifery and Gynæcology.

Time of Ligation of the Umbilical Cord.

Dr. J. G. SINCLAIR COGHILL, in his address in Obstetric Medicine, before the British Medical Association, called attention to an extremely interesting and valuable communication with reference to the time and mode of separating the fœtus and umbilical cord which has been made by Ribemont, in a recent number of *Les Archives de Tocologie*, and which shows satisfactorily the great influence of the "thoracic aspiration" of the fœtus on the umbilical circulation before its ligature. This was first pointed out by Budin; but is denied, among others, by Schücking. Determined by the manometer, it was found that—1. Tardy ligature

of the cord benefits the child by increasing the quantity of blood which is required for the establishment of the third circulation, that is, the fœtal pulmonary. 2. The immediate ligature of the cord deprives the infant of a quantity of blood, larger or smaller in proportion to the time of ligature; and it especially deprives it of necessary blood if the ligature has been applied before the child has breathed. 3. The early ligature of the cord thus compels the abstraction of the blood necessary to establish the pulmonary circulation from the general circulation. The result is a diminution of the arterial tension equal to one-third of the initial tension. 4. The cause of the penetration of the blood into the pulmonary circulatory system of the child is the "thoracic aspiration." This is proved by the constant superiority of the pressure of the blood in the umbilical arteries to that in the umbilical vein. Again, the thoracic respiration is observed to produce considerable oscillations in the tension of the arterial and venous blood. The uterine contractions are utterly insufficient to force any blood along the umbilical vein when the arterial pulsations of the cord have ceased. 5. Thoracic aspiration causes the *sufficient* and *necessary* amount of blood to enter the pulmonary vessels; *sufficient* because, under these circumstances, the tension in the arterial system does not fall; necessary because the arterial tension in the umbilical cord of a newly-born child is never seen to rise after tardy ligature of the cord. Professor W. T. Lusk, of New York, in corroborating Ribemont's views, says that, in children born pale and anæmic, and suffering from syncope, late ligation of the cord furnishes an invaluable means of restoring the equilibrium of the fœtal circulation.—*British Medical Journal*, Aug. 20, 1881.

—

Membranous Dysmenorrhœa in relation to Normal Menstruation.

In a paper read at the Académie de Médecine, Dr. SINÉTY stated that it resulted from the observations which he had made on a great number of women, that, in the physiological condition, the uterine mucous membrane is not, as is generally taught, eliminated in menstruation; but, under certain pathological conditions, the mucous membrane of the body of the uterus exfoliates, and is expelled at the catamenial period. This phenomenon, designated as "membranous dysmenorrhœa," is usually accompanied by severe pain and loss of blood. It does not constitute a special disease or morbid entity, and is observed under very variable conditions, with or without metritis. The exfoliation is the result of an exaggeration of the normal menstrual process, inducing a too great infiltration of the deeper layers of the mucous membrane and compression of the vessels of this region, and leading to elimination of the tissues situated above this layer. It will be thus understood that anything which prevents the blood issuing, as in the normal state, by the superficial vascular network of the mucous membrane, may be a cause of membranous dysmenorrhœa.—*Med. Times and Gaz.*, Sept. 24, 1881.

—

Local Treatment of Chronic Metritis.

Prof. AMANN, of Munich, read a paper on this subject, at the London Congress, of which the following is an abstract:—

Most cases of chronic metritis require local treatment for their cure. If the disease be limited to the mucous membrane of the cervical canal the treatment is comparatively simple, and cure can be affected by various harmless means. Greater difficulty is met with when chronic inflammation of the body or of the body and neck of the uterus calls for local treatment. For many years I have carefully tested the various means recommended during the last twenty years in the treatment of the affection in question, in hospital and private practice, in more than 3000 cases, and have come to the conviction that only one method

acts with certainty without being troublesome and *dangerous*. This is new only in the manner of its execution, and consists in the systematic cauterization of the cavity of the body, and eventually of the cervix of the uterus by means of an instrument like a sound, into a hollow in the upper end of which is fused lapis mitigatus. This can be employed as is self-evident, according to the behaviour of the endometrium, and the resisting power of the uterus in individual cases, at one time more frequently and thoroughly, at another more rarely and cautiously, and will have, according to the peculiarities of the special case, by itself alone, or in conjunction with other means (topical blood-letting, scraping off of growths of the endometrium), almost sure results. Only in a few cases of large tumours or severe bleeding granulations of the endometrium is the employment of the galvano-cautery or thermo-cautery necessary. The intra-uterine application of *lapis mitigatus* is, with the necessary caution, absolutely free from danger, and in a small number of cases only does it cause pain, which, however, is usually of short duration; sometimes also it gives rise to considerable but transient bleeding. Once only have I noticed, after a severe cauterization of the whole of the uterine cavity, dangerous metritis or peri-metritis, which, however, ended in a few weeks in complete recovery. Even slighter degrees of acute endometritis and acute metritis occur according to my experience in barely 2 per cent. of all the cases.

One of the chief advantages of the proceeding in question is, that it can be carried out without assistance in at least 95 per cent. of cases, and usually in five, exceptionally in ten minutes. Within this time, moreover, the cleansing of the uterine canal from mucus, a necessary preparation for cauterization, as well as the dilatation of the narrow canal by means of metallic dilators, can be accomplished. Further this procedure is applicable, when the condition is complicated by severe flexions and versions, either after straightening the organ immediately before cauterization, or if the canal be of normal width by cauterizing with the sound-like instrument forthwith. This is done without a speculum just as the sound is introduced. By reason of the rapidity of the cauterization, which is finished in three to five seconds, and because, by the revolving of the caustic holder, contact of the caustic with the individual parts of the endometrium is extraordinarily short, coating of the caustic with coagulated albumen is prevented. Immediately after cauterizing a large tampon of wadding soaked in a solution of tannin should be introduced into the vagina in order to prevent the caustic dissolved in the uterine cavity from escaping into and through the vagina.

—

Total Extirpation of the Uterus for Cancer.

This operation may be said at present to be on its trial; for surgeons are not yet agreed as to whether the prospect of benefit outweighs the risk. The statistical accounts that have as yet been published are incomplete, and therefore not quite in agreement. We want figures to show us, first, in what number of cases the operation itself proves fatal, and then, in how many of those who recover from the operation the disease returns. The statistics are not in agreement; first, because improvements are being made in the *technique* of the operation, and in estimating the probable future mortality of an operation, we must reject cases in which the operation was not done in the way which better knowledge has shown to be the safest, and also because some cases, published as cures, have afterwards relapsed. Bearing in mind these errors, the following statistics will be interesting: Mikulicz (*Wiener Medizinische Wochenschrift*, 1880, No. 47) quotes from Ahlfeld a table of 66 cases, out of which 49 proved fatal, in 4 the operation could not be completed, and of the 13 who recovered, in 6 relapses occurred; of the remain-

ing 7, in some the period since the operation, at the time the figures were compiled, was too short to allow the occurrence of relapse to be considered improbable. Some later statistics are more favourable. KLEINWACHTER, writing at the beginning of the present year, collected 94 cases of operation, with 24 recoveries; but KALTENBACH, writing about the same time, out of 88 cases enumerates 30 as successes. These figures evidently want sifting. They all relate to cases in which the uterus has been extirpated by abdominal section. OLSHAUSEN has collected (*Berliner Klinische Wochenschrift*, No. 35, 1881) 41 cases in which the uterus was removed by the vaginal method; of these 29 recovered and 12 died. To these he adds 6 performed by himself, all of which, so far as the operation was concerned, were successful.—*Med. Times and Gaz.*, Sept. 24, 1881.

—

The Ovary in Incipient Cystic Disease.

Dr. VINCENT D. HARRIS, Demonstrator of Physiology at St. Bartholomew's Hospital, and Mr. ALBERT DORAN, Surgeon to Out-Patients, Samaritan Free Hospital, having enjoyed exceptional opportunities for studying incipient cystic disease of the ovary, have, in a joint paper, contributed the results of their observations to the *Journal of Anatomy and Physiology*, July, 1881. In over one-eighth of the cases operated upon at the Samaritan Hospital Dr. Bantock and Mr. Knowsley Thornton find that, after the removal of a large ovarian cyst, the opposite ovary presents such distinct symptoms of early cystic disease, that they remove it, knowing that otherwise a second operation will almost assuredly be necessary at no very distant date. A large number of such ovaries have been collected, and their appearances, when fresh, carefully described; the history of the patients, and notes as to the absence or regularity of the menstrual functions, together with records of abortion, parturition, or sterility, have also been preserved. The ovaries, within a few hours after removal, were placed within a half per cent. solution of chromic acid mixed with equal parts of methylated spirit. When sufficiently hardened, sections were prepared from them by means of Williams's freezing microtome. These sections were stained in logwood solution, and then mounted. Lastly, all have been since examined minutely by Dr. Harris and Mr. Doran, and separate notes carefully compared.

The results of their researches are summarized as follows:—

1. There is strong evidence that multilocular cystic disease of the ovary may arise from two totally different ovarian elements.

2. Cysts may arise from partial dilatation and partial obstruction of enlarged and thickened bloodvessels, as Noeggerath maintains,[1] and we think, as he does, that many errors have arisen from imperfect knowledge of the appearance of bloodvessels in the ovarian stroma.

3. Cysts more frequently appear to originate in changes in those Graafian follicles that undergo involution without having ever ruptured; this includes a large majority of the follicles, when we remember the vast number found in the ovary at birth, and bear in mind that involution of many follicles takes place between birth and puberty.

4. The morbid changes which replace normal involution of the follicle are an active ingrowth from the stroma, and a long persistence of the cloudy tube-like bodies that represent the remains of the membrana propria of the follicle. These two processes sometimes proceed at an equal rate, sometimes irregularly.

5. When the relics of the membrana propria are slow to disappear, and the stroma slowly sends ingrowths amongst these relics, we find the cystic bodies

[1] "The Diseases of Bloodvessels of the Ovary in Relation to the Genesis of Ovarian Cysts." Amer. Journ. of Obstetrics, etc., vol. xiii., 1880.

described as seen in the fourth case, containing myxoma-cells partly, at least, connected with the outgrowths. Such delicate tissue, made up of these cells, must soon break down as the cyst becomes larger.

6. When the process of ingrowth of stroma into the follicle, during involution, is particularly active, the ingrowths interlace and rapidly form cystic spaces, including portions of the cloudy relics of the membrana propria, giving the appearances seen in the third case.

7. On the other hand, the stroma may show little or no tendency to develop ingrowths, but the relics of the membrana propria may break down very slowly, and end, not in simple effacement and incorporation with the stroma, but in slowly breaking down, as in the second case. This must necessarily end in the formation of a cyst full of a colloid or semi-fluid material, the completely broken down granulosa, etc.; previous theories on colloid degeneration of the stroma itself may be based on the overlooking of the intra-follicular origin of the colloid collections. In all cases of myxomatous or colloid changes, or simple rarefaction of tissue, we found full evidence that those changes were in degenerate follicles and never free in the stroma.

8. All these changes in the degenerating membrana propria and the tissue surrounding the follicle, begin as exaggerations of the normal process of involution, which is never a mere disintegration and degeneration of the follicle. Slavjansky, in the work we have quoted, gives accurate drawings of the normal process. Patenko traces these abnormal changes to sclerosis of the follicle-wall, under different conditions.[1]

9. These changes in the follicle do not appear due to inflammation; indeed, in old inflamed ovaries the atrophy of the follicles appears to be quicker and more complete than in healthy ovaries, so that no trace of them is left, excepting certain granular masses.

10. The manner in which the young cyst first becomes invested with its characteristic epithelium is obscure. We found that the "germinal epithelium" of the tunica albuginea and the cells of the granulosa of normal follicles never invaded the ovarian stroma, and the epithelial relics of the Wolffian tubes, that are usually found loose about the stroma, were never in close relation to any of the bodies we have described. In the case of the dilated vessels, the endothelium must be the most natural starting point of the epithelial lining of cysts derived from such vessels. Remembering the changes in the mucous membrane of a prolapsed vagina, the endothelium may, we can conceive, alter its character when the nature of the free space on which it borders has become completely altered. Should the theory of Cripps[2] be even partly correct, that nuclei in lymphoid or connective tissue may gather protoplasm around them till they form real epithelioid bodies lining spaces deeply situated in solid structures, we could readily account for the origin of the epithelial lining of any cyst. We do not profess to accept as positive that observer's theory, that the nuclei in the submucous tissue of the rectum are normally the parents of the columnar epithelium of the mucous membrane, although microscopical evidence tends to support it; his other opinion, expressed above, that such nuclei may become epithelioid, is far more probable. An area in any tissue, with such nuclei, breaks down—the nuclei bordering on the broken-down region must be placed at once in different circumstances to their normal state, deep in tissue and away from any free surface. We do not find such nuclei on free surfaces; we do find epithelium. In other words, we

[1] In Virchow's Archiv, May, 1881, he demonstrates the manner in which this process ends in the formation, not of cysts, but of "corpora fibrosa."

[2] Cancer of the Rectum. See particularly Pl. III. fig. 1, in that work.

see no difficulty in supposing that the epithelial lining of ovarian cysts is probably developed from nuclear elements in the bodies above described. It seems, on mere reasoning, less far-fetched to assert that this epithelial lining is derived from pre-existing epithelium. To this we reply that, on actual observation, detecting incipient cystic cavities and also healthy epithelium on the tunica albuginea, in the follicles, and, as embryonic relics in the stroma, often in one single section, we find no connection between the cavities and any of these three normal epithelial elements. We must not conclude that when the mucoid contents of the imperfectly involved follicles have broken down to their utmost, the cellular elements immediately adjacent to the resulting semi-fluid material, simply assume the epithelial type. Only as long as the source whence normal epithelium is renewed remains obscure, so long must this question remain unsettled.

—

Remarks on Antiseptic Ovariotomy.

Mr. KNOWSLEY THORNTON made the following remarks to a number of the members of the International Medical Congress who assembled at the Samaritan Hospital, on Aug. 3d:—

This being, he said, the last of our regular operation days before the hospital is closed for its autumn cleaning, I think it is a good opportunity to make a statement as to the work done in my wards since the 1st of January in this year. I have performed ovariotomy twenty-eight times, and I have only lost one patient, a child of fifteen, from whom I removed a solid carcinoma of 7 lbs. weight, involving both ovaries, the cæcum, and sigmoid flexure, so that I had to carve the intestines out of the solid growth. She died of exhaustion in forty-eight hours. Every one of these operations was performed with the 2½ per cent. spray, and solutions of absolute phenol (pure carbolic acid), and in no case was drainage employed. All the wounds healed by first intention, and the dressings were changed for the first time as a rule from the ninth to the twelfth day, when all the sutures were removed. Nineteen of the patients recovered without fever (*i.e.*, the temperature never rose even during reaction beyond 101° F.); five had temperatures from 101.6° to 103.4° during a few hours, but required no special treatment; four had temperatures from 102.8° to 104.6°, and required the use of the ice-water cap during periods of from thirty-nine hours to sixty-eight hours. These nine cases were all of more than usual gravity, with large tumours, extensive adhesions, long exposure, and much sponging. Only two of the patients remained in the hospital twenty-eight days after operation: one a patient from whom I removed an extensively adherent tumour weighing 80 lbs.; and the other one of the cases requiring the ice-water cap; a case of ruptured colloid, which I kept in bed longer than usual. The average stay in hospital after operation of the other patients was twenty days and a half, the shortest seventeen days. There were no adhesions in fourteen cases, slight adhesions in one case, and extensive adhesions with other complications in thirteen cases. In nineteen of the cases only one ovary was removed; in the others both were diseased and removed. To these twenty-eight cases of my own, I may add four cases operated upon in my wards by my colleague, Mr. MEREDITH, in which strict Listerism without drainage was also employed; all recovered. So that we have thirty-two Listerian ovariotomies without drainage with only one death, and that a case of cancer. I have also performed eight other abdominal sections: A removal of uterine fibro-cyst, weighing 28 lbs., together with both ovaries; a removal of several sessile and pediculate fibroids; an enucleation of a uterine fibro-cyst weighing 10 lbs.; a complete hysterectomy, with removal of both ovaries; and three cöphorectomies, undertaken for various conditions. All the patients recovered with the exception of the hysterectomy, and she died of septicæmia. I had to open a

much enlarged uterine cavity, which contained putrid material, and I failed to correct the putrefaction. This was the only case in which it was impossible to perform a strictly aseptic operation, and it was the only one terminating fatally. The total result is forty abdominal sections, with two deaths—a mortality of only 5 per cent. I may add that in no case were there symptoms of carbolism, though the 2½ per cent. solutions were used with all necessary freedom, and some of the patients had albuminuria before the operation.—*Lancet*, Aug. 20, 1881.

Medical Jurisprudence and Toxicology.

Notes of a Case in which Chrysophanic Acid was Administered Internally by Accident.

Mr. JOHN GLAISTER reports in the *Glasgow Med. Journ.* for October, 1881, a case in which the patient was given a powder containing, by accident, a three-grain dose of chrysophanic acid, having been in fairly good health before. Within two hours after she was seized with the symptoms of irritating poison—burning pain in stomach, vomiting, pain in bowels, diarrhœa, hæmaturia, and pain over bladder, with tenesmus. It would, therefore, seem clear that the symptoms followed the medicine—*post hoc propter hoc*. It was also very evident from the symptoms that considerable irritation was produced in the gastro-intestinal and urinary tracts, occurring in that order. Hence, Mr. Glaister infers that a dose of three grains acts as a strong irritant. The colour of the matter first vomited, and the urine, point to the chrysophanic acid, because it is well known to produce coloured stains on linen coming in contact with it when used in an ointment.

But what are we to say about the bladder condition? The prolonged retention of urine pointed to one of two things—paralysis of the bladder through inflammation or disinclination to initiate the act of micturition owing to the great pain felt during that time. That there was inflammation of the bladder there can be no doubt, the persistent pain over that region indicating as much; and that this inflammation had ended in ulceration Mr. Glaister is inclined to believe, although some may gainsay it. He feared that the catheterism had had something to do with its production, but it was after the lengthened use of the catheter, when the parts had become accustomed to it, that the blood made its appearance, consequently he inclines rather to the previous explanation.

Previous to this case Mr. Glaister was not acquainted with the internal use of chrysophanic acid, and it was only in looking into the literature of this drug that he fell upon the recorded observations of Dr. Ashburton Thompson in the *British Medical Journal* for 19th May, 1877, pp. 607–8, where he calls chrysarobin—the powder in which chrysophanic acid exists to the extent of 80 per cent.—"a new emetic purge." The action of the powder in doses of six grains to children of twelve, according to this experimenter, produced the following effects:—"Vomiting is always the first sign of action. This is not attended by any depression at all comparable with that caused by tartar emetic or ipecacuanha. In the doses presently to be named, it has not caused any distressing retching; and in children, as well as in adults, the acts of vomiting varied between nine in three out of the number, and six in two out of the whole number. They were usually two or three; very often only one. The action on the bowels was much more variable—from none in a few cases to nine or ten in equally few cases; most often the range was between three and seven. There is no griping pain, but the nausea continues more or less markedly until the bowels recover. . . . If the dose be taken into a full stomach, that delays its action and determines it

to the bowels." Dr. Thompson concludes "that chrysarobin is, in a dose of twenty-five grains for adults, or of six or more grains for children, an emetic purge of which the action is unattended by any inconvenient symptoms." Then as to the action of chrysophanic acid, pure. The same observer says that its action "is similar to the action of chrysarobin, with this difference, that while in a suitable dose each will cause vomiting and purging, if the dose be too small, chrysarobin is most likely to purge only, while chrysophanic acid is most likely to cause vomiting only." . . . A dose of "from fifteen to twenty grains will always both vomit and purge the patient very freely, at the same time that it causes an inconvenient amount of either of those effects very rarely indeed. Farther, there is but little danger of inconvenience from too large a dose."

The dose of the drug, as recommended by Dr. Thompson, is from six grains upwards.

Wood, in his *Treatise on Therapeutics*, p. 437, speaking of the action of this acid, says that "according to Schlossberger, Bucheim, Meykow, and Auer, it is not purgative; but Schroff has found it to be so."

In Professor Charteris' cases, recorded in the *Lancet* lately, where comparatively large quantities of strong chrysophanic acid ointment were used externally, symptoms of gastro-intestinal irritation always asserted themselves in the early part of the treatment, but afterwards disappeared. It is therefore quite clear that this acid acts as a gastro-intestinal irritant; the question which then naturally suggests itself is, Can it be given internally in doses which would produce therapeutic action, and fall short of producing severe symptoms such as experienced by my patient? In answer to this, Dr. Thompson, after an extended series of observations in the use of the drug, says that such a dose can be given without producing severe results. This case of Mr. Glaister, however, shows that even such a small dose as three grains will produce effects which *are* unpleasant and very severe; and it also points to the fact that its effects are not always to be referred to the gastro-intestinal tract simply, but to the urinary tract also. The question has now arisen in the minds of some of those who are accustomed to the use of this drug externally in skin diseases, whether the same beneficial effect now obtained by such use could not be more speedily and comfortably got by its internal administration. This has arisen from the fact that, in some cases, where the acid ointment has been applied only to one side of the body, the other, perhaps equally as much affected, has been nearly as quickly cured; and this would point to the absorption of the drug into the body. Every one knows that it cures skin affections by the irritant action it produces where it is applied—by its altering the character of the inflammatory condition producing the chronic disease, and giving it, as it were, a more acute tone. But how does it act internally? It certainly acts as an irritant, but whether directly as the metallic irritant poisons, or indirectly as apomorphia, is a question not yet settled. The presence of food in the stomach prevents its early action, thereby pointing in the direction of the behaviour of an ordinary metallic irritant. Its mode of exhibition, too, influences the rapidity of its action; when given with an alkaline solution, it acts more quickly, things being equal, than it does undissolved, as in water or an acid medium. So that, given in a powder, as in the case of my patient, and into an empty stomach, it will, by reason of its being undissolved in the water used as a vehicle for taking it, and also because it would remain undissolved in the acid contents of the stomach, probably act as a direct irritant; when, however, it has been exhibited dissolved, as in an alkaline solution, or where it has passed from the stomach with food and only been dissolved by contact with the alkaline juice of the pancreas, and then absorbed, it will probably act as an indirect irritant.

In the light of the foregoing case, Mr. Glaister confesses, even in the face of the recorded observations of Dr. Thompson, that he would be very chary as to the dose he would administer internally. Probably an unpleasant introduction to the use of a drug regulates one's feelings as to its general behaviour, and possibly that may be so in my case: in any case, I would prefer to begin its administration internally in much smaller doses than are recommended by Dr. Thompson.

Possibly, again, the element of idiosyncrasy had something to do with its severe behaviour in the person of Mr. Glaister's patient; that much might be argued; but he doubts if any one would question the severity of the effects, which were carefully noted as they appeared, more with the view of being recorded as the eccentric behaviour of the euonymin, no suspicion having arisen in my mind at the time as to an error in the dispensing of the powder.

A Case of Nicotine Poisoning.

A case of poisoning, with sudden death, is reported by L. L. DORR, occurring in a cigar-maker 49 years of age, and apparently due to excessive smoking and prolonged presence in a room filled with tobacco smoke. At the autopsy, the description agreed with von Borck's description of the morbid state (*vide Ziemssen's Cyclopœdia*), viz., "The heart is generally empty, and the blood in the vessels is of a dark-red colour. The liver, spleen, and kidneys are generally hyperæmic. Vascular engorgements of the brain and its membranes, and serous fluid in the ventricles of the brain, are mentioned in almost all published reports."—*New Remedies*, March, 1881.

Iron as a Poison.

ORFILA demonstrated that large doses of sulphate of iron will cause death with symptoms of collapse and insensibility, and, post mortem, congestion and ecchymoses in the gastro-intestinal mucous membrane, and remarkable black discoloration of the blood. Frank arrived at similar results, employing the citrate or bromhydrate. Recently MEYER and WILLIAMS have found similar effects from the subcutaneous injection of the potassio-tartrate of iron, slightly alkalized. About seventy-five thousandths of a grain constitutes a poisonous dose for the frog, and about six-tenths of a grain for a rabbit. In the frog, after absorption, there are paralysis of movement and disappearance of muscular irritability, without affection of the heart. In rabbits a great acceleration of the respiratory movements is first produced, and at the end of a little time diarrhœa comes on, with muscular weakness, while paralysis of movement, dyspnœa, and convulsions precede death. The lungs and heart are found healthy, the duodenum is swollen and hyperæmic, the mesenteric glands are engorged, and the liver, kidneys, and spleen are congested. Similar effects are produced in the cat by four or five tenths of a grain, and in the dog by rather more per pound of body weight. The toxic symptoms are accompanied by a remarkable diminution of blood-pressure, explicable by vascular paralysis. There is also observed the black tint of the blood signalized by Orfila, which is not, as might be imagined, due to the accumulation of carbonic acid in the blood, since analysis proves that this is really diminished.—*Lancet*, Sept. 24, 1881.

Hygiene.

Prevention of Scarlet Fever.

Dr. DAVID PAGE, at the London Congress, made some interesting remarks on this subject, in which he said, at the outset, that those precautions which, in

respect of scarlet fever, prove successful for the protection of a neighbourhood or a household, must also be the real defences for the community which is immediately concerned, and therefore for other and more distant communities. All national or international preventive measures against the diffusion of such a disease as scarlet fever must, in their essence, be measures for effectual individual control. These measures ought to give practical effect to the questions:—

1. What ought to be done with the infected individual or patient?
2. How long may the patient continue to be a possible source of infection?
3. What is the latest period, after exposure to infection, at which the disorder will show itself in a person who has received the infection into his system?
4. How soon may a person who has been exposed to risks of infection be pronounced safe against attack?

Two main clinical facts are involved in these questions:—

1. The duration of the incubation period of scarlet fever.
2. The modes of exit from the system of the fever poison.

A knowledge of the incubation period essential in disposing for the time of a person, who, having been exposed to chances of infection, may have contracted the disorder. In this case an appreciation of the maximum period of latency required. Literature of subject vague and untrustworthy.

The author's observations coincide with those of the late Dr. Murchison, and may be summed up:—

1. The common duration of the incubation period in scarlet fever is from twenty-four to forty-eight hours.
2. The period is occasionally longer, lasting from three to five days.
3. In rare instances practically absent, the symptoms following quickly upon exposure to infection.

Based upon these conclusions, the author requires that a person who has been exposed to infection should, before being pronounced safe from its probable consequences, be kept under surveillance for a week, and only then, after change of clothes, and baths, be set at liberty.

Of even greater importance than this is the action which ought to be taken in regard to the fever patient himself. This action is rendered difficult by reason of diversity and inconstancy of what are commonly looked for as the diagnostic features of scarlet fever.

An estimate of the real value of desquamation of the cuticle as a trustworthy guide in preventive measures must be based upon knowledge of irregularity of process in relation to time, quantity of eruption, or intensity of attack. Error of regarding infective process at an end before cessation of desquamation and *for some considerable interval afterwards*. Importance of pathology of scarlet fever as regards the nature of the eruption and the tendency to albuminuria, as a guide to preventive action and treatment.

The author's experience points to the necessity for isolation of the scarlatinal patient for a period of not less than eight weeks, and he would state the rule of Nature to be isolation for this period as a minimum, and, in cases of protracted desquamation or of relapse, until entire cessation of the process *and for a fortnight afterwards*.

For the rest, official action should include:—

1. Due provision for the separation of the sick from the healthy in the way of hospitals and convalescent homes.
2. Notification of the occurrence of cases of infectious disease.
3. Continuous supervision of all scarlatinal convalescents.
4. Control of school attendance of children belonging to infected families.
5. Disinfection and purification of infected houses and things.

MEDICAL NEWS.

Defective Plumbing and Drainage.

Our publication in the present number of the excellent plan of plumbing and drainage, approved by the New York City Board of Health, will we trust direct attention to a subject which requires the most careful consideration, not only in this community, but also in every town and even in every village throughout our country. The people of America stood aghast, as they well might, before the devastation caused a few years since by yellow fever, in New Orleans and Memphis; and yet it is probable that twice as great a proportionate annual mortality occurs, in every closely built city, from typhoid fever, diphtheria, and allied diseases, resulting from sanitary faults in plumbing and drainage.

That these dangers to our health and our lives are real and imminent, is shown by a moment's glance at the record of facts brought to light by Dr. H. R. Storer in his valuable report of the workings of the Sanitary Protective Association of Newport, R. I., in which he relates that the inspecting engineer of the society had found soil pipes both of iron and clay cracked, that joints were discovered having no cement or solder whatever, while frequently they were merely plastered over, leaving spaces whence sewage escaped; other joints being found so imperfectly closed, that rootlets of trees had entered, and by their growth entirely plugged up the pipe, with the result of backward flow and leakage of sewage. Soil pipes were likewise met with where old fractures had been plugged with wood, which in time, of course, had rotted away, and allowed sewer-gas to escape. Direct communications were unearthed moreover, between house and cess-pool, with no intervening trap, detection being made through inspection alone, there being no perceptible odour, although such must have been the state of things for more than a year, in some instances.

Last but not least in the long list of faults actually revealed by inspection, in the houses of subscribers to the Newport Association, it is to be noticed, that cess-pools were constantly discovered in close proximity to wells, thus suggesting an examination of the well water, which was rarely found good in any portion of the city.

Among medical men of the present generation, there exists, it is to be hoped, little need of dwelling upon this unsavory subject, but we desire to urge on every physician whose eyes these remarks meet, the vital importance of impressing upon his circle of friends and patients, how dangerous

to health are these constantly occurring blunders of defective plumbing. Thousands of valued lives have been sacrificed by typhoid fever, through the ignorance of architects and builders in regard to the first principles of sanitary drainage; and tens of thousands of beloved children have died from diphtheria and other filth diseases, in consequence of culpable carelessness or deceit on the part of plumbers.

The philanthropic efforts of sanitarians would probably be much aided, if the public could be persuaded to understand, that the risk of contaminating the human organism with the poison of typhoid fever (and perhaps of other diseases) is twofold; that is to say, the typhoid germ may enter our bodies by way of drinking-water (into which it finds its way in consequence of faulty construction and arrangement of drain pipes, etc.); or it may gain access to our systems through the lungs, by our breathing-air (if that air becomes mingled with sewer- or cess-pool gas), as a result of leaky and defective pipes, traps, or reservoirs for sewage. Moreover, it must always be remembered that no plumber's work, however complete it may be at first, can be relied upon to remain perfect; and that therefore the only sewage and drain-pipe arrangement, which is worthy of any confidence, is one in which nothing is concealed, but all parts may be easily inspected and repaired, whenever and wherever the slightest defect is found to exist.

In his efforts to secure due attention in the community to this all-important subject of proper plumbing and drainage, the sanitarian is baffled by an incredulity as to the impending danger, based upon the circumstance that individuals were known to have drunk water contaminated with the soakage of a cess-pool, or breathed air rendered foul by the emanations of a leaky trap or drain pipe, *for years* without apparent injury. Hence it is furthermore very important to disseminate in the community a knowledge of the fact that air or water rendered impure by admixture with simple ordinary filth, may be taken into the economy for a long time without obvious ill effects, but if this filth becomes infected with the specific poison or *germ* of typhoid or diphtheria (as may happen at any time, by the passage into it of the excretions from a person affected with either of these maladies), it is changed at once into the virulent carrier of disease. No better illustration of this great truth could well be given than the remarkable instance recorded by Prof. Flint, in which a young man travelling by stage coach in Vermont, fell ill with typhoid, was left at the hotel of a wayside hamlet, and within a week infected with his malady (through his intestinal discharges) all the families on the tavern side of a creek, which divided the village, *except one* whose head had quarrelled with the landlord, and drank none of the water from his well. Doubtless in this case the tavern-keeper's well-water had been contaminated with sewage from the hotel for years, and it would seem without serious injury to those using it, yet directly after the simple filth it previously contained was impreg-

nated, *in addition*, with the self-propagating germ of typhoid fever, this hitherto comparatively innocent water was altered into a powerful and deadly poison, for those who drank it. So strong is this single item of evidence, in regard to the dangers arising from impure water, that could it alone, without any other testimony, be heard by every one, we might soon expect a vast diminution in the evils from defective plumbing and drainage throughout the civilized world.

—

Rules for Drainage and Plumbing.—A system of rules to govern the plumbing and drainage of all buildings hereafter erected in New York has been adopted by the Health Board, in accordance with the power conferred upon it by the statute enacted by the State Legislature June 4, 1881. These rules were distributed to plumbers on October 11, and are as follows:—

1. All materials must be of good quality and free from defects; the work must be executed in a thorough and workmanlike manner.

2. The arrangement of soil- and waste-pipes must be as direct as possible.

The drain-, soil-, and waste-pipes, and the traps, should, if practicable, be exposed to view for ready inspection at all times, and for convenience in repairing. When placed within walls or partitions, they should be covered with woodwork, fastened with screws, so as to be readily removed. In no case should they be absolutely inaccessible.

It is recommended to place the soil and other vertical pipes in a special shaft, between or adjacent to the water-closet and the bath-room, and serving as a ventilating shaft for them. This shaft should be at least two and a half feet square. It should extend from the cellar through the roof, and should be covered by a louvered skylight. It should be accessible at every story, and should have a very open but strong grating at each floor to stand upon.

3. Every house or building must be separately and independently connected with the street-sewer by an iron pipe caulked with lead.

4. The house-drain must be of iron, with a fall of at least one-half an inch to the foot, if possible.

It should run along the cellar-wall, unless this is impracticable, in which case it should be laid in a trench, cut at a uniform grade, walled up on the sides, and provided with movable covers, with a hydraulic concrete base of four inches in thickness on which the pipe is to rest.

It should be laid in a straight line, if possible. All changes in direction must be made with curved pipes, and all connections with Y-branch-pipes and one-eighth bends.

It must be provided with a running trap placed at an accessible point near the front of the house. The trap must be furnished with a hand-hole for convenience in cleaning, the cover of which must be properly fitted and the joints made tight with some proper cement.

There should be an inlet for fresh air entering the drain just inside the trap of at least 4 inches in diameter, leading to the outer air and opening at any convenient place not too near a window.

No brick, sheet-metal, or earthenware flue shall be used as a sewer-ventilator, nor shall any chimney-flue be used for this purpose.

5. Every soil-pipe and waste-pipe must be of iron, and must extend at least two feet above the highest part of the roof or coping, of undiminished size, with a return bend or cowl. It must not open near a window nor an air-shaft ventilating living rooms.

Horizontal soil- and waste-pipes are prohibited.

There should be no traps on vertical soil-pipes or vertical waste-pipes.

6. All iron pipes must be sound, free from holes, and of a uniform thickness of not less than one-eighth of an inch for a diameter of two, three, or four inches, or five thirty-seconds of an inch for a diameter of five or six inches; and for large buildings the use of what is known as extra heavy soil-pipe is recommended, which weighs as follows:—

2	inches,	5½	pounds	per	lineal foot.
3	"	9½	"	"	"
4	"	13	"	"	"
5	"	17	"	"	"
6	"	20	"	"	"
7	"	27	"	"	"
8	"	33½	"	"	"
10	"	45	"	"	"
12	"	54	"	"	"

Before they are connected they must be thoroughly coated inside and outside with coal-tar pitch, applied hot, or some other equivalent substance.

Iron pipes, before being connected with fixtures, should have openings stopped, and be filled with water and allowed to stand twenty-four hours for inspection.

7. All joints in the drain-pipes, soil-pipes, and waste-pipes must be so caulked with oakum and lead, or with cement made of iron filings and sal ammoniac, as to make them impermeable to gases.

All connections of lead with iron pipes should be made with a brass sleeve or ferrule, of the same size as the lead pipe, put in the hub of the branch of the iron pipe and caulked in with lead. The lead pipe should be attached to the ferrule by a wiped joint.

All connections of lead pipe should be by wiped joints.

8. Every sink, basin, wash-tray, bath, safe, and every tub or set of tubs, must be separately and effectively trapped. The traps must be placed as near the fixtures as practicable. All exit-pipes should be provided with strong metallic strainers.

9. Traps should be protected from siphonage by a special metallic air-pipe not less than one and one-half inch in diameter; if it supply air to a water-closet trap, not less than two inches in diameter, the size to increase with the number of water-closets.

These pipes should extend two feet above the highest part of the roof or coping, and, if independent of the upper end of the soil-pipe, this extension should not be less than four inches in diameter to avoid obstruction from frost. If, however, they are branched into a soil-pipe, it must be above the inlet from the highest fixture. They may be combined by branching together those which serve several traps. These air-pipes must always have a continuous slope, to avoid collecting water by condensation.

10. Every safe under a wash-basin, bath, urinal, water-closet, or other fixture must be drained by a special pipe not directly connected with any soil-pipe, waste-pipe, drain, or sewer, but discharging into an open sink, upon the cellar-floor, or outside the house.

11. No waste-pipe from a refrigerator shall be directly connected with the soil- or waste-pipe, or with the drain or sewer, or discharge into the soil, but it should discharge into an open sink. Such waste-pipes should be so arranged as to admit of frequent flushing, and should be as short as possible, and disconnected from the refrigerator.

12. All water-closets inside the house must be supplied with water from a special tank or cistern, the water of which is not used for any other purpose. The closets must never be supplied directly from the Croton supply pipes. A group of closets may be supplied from one tank, if on the same floor and contiguous.

The overflow-pipes from tanks should discharge into an open sink or into the bowl of the closet itself, not into the soil- or waste-pipe, nor into the drain or sewer. When the pressure of the Croton is not sufficient to supply these tanks, a pump must be provided.

13. Cisterns for drinking-water are objectionable; if indispensable, they must never be lined with lead, galvanized iron, or zinc. They should be constructed of iron or of wood, lined with tinned and planished copper. The overflow should be trapped, and should discharge into an open sink, never into any soil- or waste-pipe or water-closet trap, nor into the drain or sewer.

14. Rain-water leaders must never be used as soil-, waste-, or vent-pipes; nor shall any soil-, waste-, or vent-pipe be used as a leader.

When connected with the house-drain, the leaders should be trapped beneath the ground, with a deep seal, to avoid evaporation, and, if placed within the house, must be made of cast-iron, with leaden joints.

15. No steam-exhaust will be allowed to connect with any soil- or waste-pipe.

16. Cellar- and foundation-walls should be rendered impervious to dampness, by the use of asphaltum or coal-tar pitch in addition to hydraulic cement.

Subsoil drains should be provided whenever necessary.

17. Yards and areas should always be properly graded, cemented, flagged, or well paved, and drained by pipes discharging into the house-drain. These pipes should be effectively trapped.

18. No privy-vault, or cesspool for sewage, will be permitted in any part of the city when a sewer is accessible.

—

Raid on Poor Milk.—The New York Health Board is at present engaged in very energetic efforts to prevent the sale of inferior milk. The milk inspectors make careful examinations of the milk when it reaches the city, and pour into the street all that does not conform to the standards and tests established by the Board. 5000 quarts of poor milk were thus spilled during the last week in September. A large number of milk dealers have also been arraigned and fined for the sale of adulterated and inferior milk.

—

The International Pharmacopœia.—A project of no small importance—viz., construction of an International Pharmacopœia, which should include a common mode of preparing and prescribing the more important drugs—has been considerably advanced during the last month, as the result of the conference of the International Pharmaceutical Congress held in London. The following resolutions were unanimously passed at this Congress; and will, we believe, be practically acted upon:—

"1. The fifth International Pharmaceutical Congress, held in London, confirms the resolution passed at the previous Congresses, as to the utility of a Universal Pharmacopœia, but is of opinion that it is necessary at once to appoint a Commission, consisting of two delegates from each of the countries represented at this Congress, which should prepare within the shortest possible time a compilation in which the strength of all potent drugs and their preparation is equalized. 2. The Executive Committee of this Congress is requested to take the necessary steps that the resolution be speedily carried out. 3. The work, when ready, should be handed over by the delegates to their respective Governments or their

pharmaceutical committees. 4. It is desirable that the Committee suggest an uniform systematic Latin nomenclature for the Pharmacopœias of all countries. 5. It is desirable that the Committee take measures that an official Latin translation be made of the Pharmacopœias of different countries which are not now published in that language. 6. It is desirable that the Committee be put in possession of all the manuscripts, including the documents relating to the Universal Pharmacopœia, compiled by the labours of the Society of Pharmacists of Paris, presented at the fourth meeting of the International Congress of St. Petersburg by the Society of Pharmacists of Paris. 7. That the pharmaceutical societies of the respective countries be requested to nominate those members of the Commission not appointed by this Congress, and to fill up any vacancies which may arise from time to time."—*British Med. Journal*, Aug. 20, 1881.

The representatives of the United States on this Committee are Mr. J. M. Maisch, of Philadelphia, and another to be chosen.

—

Health of New York.—The city's mortality for September somewhat exceeded that of August. For the week ending Sept. 3, there were 864 deaths. For the weeks ending Sept. 10, 17, and 24, there were respectively 866, 688, and 705 deaths. The total number for September thus amounted to upwards of 3100, while that for August was about 3000. The increased mortality may in a measure be accounted for by the fact that unseasonable, and, at times, excessive heat prevailed during almost the entire month, and gave rise to many fatal cases of infantile gastro-enteritis. The records of the Bureau of Vital Statistics show that 28,567 deaths have occurred during the past nine months. This number exceeds that for the corresponding period of 1880 by 4715. The total number for 1880 was 31,866, while the present indications are that this year's mortality will reach nearly 38,000. This death record, if actually reached, would be the highest known since the establishment of the Bureau, the next highest being that of 1872, which was 32,647.

The Board of Health cherish strong hopes that their strict suspension of all new plumbing work, and their active crusade against bad milk, will notably improve the city's sanitary condition in future by diminishing the cases of zymotic disease.

One case of typhus fever was discovered in the city during the week ending Sept. 24, but the premises upon which it was detected were so thoroughly fumigated and cleansed that no extension of the disease is apprehended. All the infectious diseases have diminished to a very encouraging extent during September. Only 46 cases of smallpox were reported as contrasted with 75 in August. Diphtheria diminished from 355 in August to 276 in September, while scarlatina and rubeola fell from 320 and 96 in August to 259 and 36 respectively in September. So excessive was the September heat that a number of sunstrokes occurred during the month.

—

The American Gynecological Society held its sixth annual meeting in New York, at the hall of the Academy of Medicine, on Sept. 21, 22, and 23. Owing to the absence of the President, Dr. Byford, of Chicago, the duties of presiding officer were discharged by the First Vice-President, Dr. Thaddeus A. Reamy, of Cincinnati. The address of welcome to the delegates was delivered by Dr. Fordyce Barker, President of the New York Academy of Medicine. Receptions were held during the session of the Society by Drs. Isaac E. Taylor and T. A. Emmet. Lunch parties were given by Drs. Sims, Thomas, Barker, Byrne, and Skene. Papers were read by Drs. Thomas; A. H. Smith, of Philadelphia; Campbell, of Augusta, Ga.; Taylor, of N. Y.; Goodell, of Philadelphia; Lyman, of Boston;

Garrigues, of N. Y.; and others. The officers elected for the ensuing year are as follows: President, Dr. T. A. Emmet, of New York; Vice-Presidents, Dr. George H. Lyman, of Boston, and Dr. E. Noeggerath, of New York. Council, Drs. Geo H. Bixby, of Boston; Jas. D. Trask, of Astoria, N. Y.; H. J. Garrigues, of New York; and G. J. Englemann, of St. Louis.

—

Epidemic of Typhoid Fever.—An endemic of typhoid fever which recently occurred in the Roman Catholic Orphan Asylum was believed to be due to the poor quality of the milk with which the institution was supplied. The analysis of the milk, made by the officials of the Health Board, showed it to have been skimmed and watered.

—

Pink Eye.—Numbers of horses in the large stables of various New York car companies have recently been attacked by influenza. It is called "pink eye" by the hostlers. Its symptoms are œdema of the legs, conjunctivitis, Schneiderïtis, tonsillitis, and bronchitis. Veterinary surgeons believe that the conjunctivitis may be relieved by steaming the animals' heads. The disease has thus far been of a mild type.

—

The British Medical Association—The forty-ninth annual meeting of this Association commenced at Ryde on the 9th of August, and lasted four days. Professor Humphry, of Cambridge, President of the Association, was in the chair. Mr. Benjamin Barrow, of Ryde, was unanimously elected President for the ensuing year, and Mr. Humphry, in a few well-chosen words, handed the office over to his successor. Mr. Barrow delivered the customary presidential address.

Mr. Fowler, the General Secretary, read the annual report of the Council, which, among other things, stated that the roll of members now reached 9202, and that the next meeting would be held at Worcester, 1882, being the jubilee year of the Association, and Worcester the town where it was first started by Sir Charles Hastings fifty years previously. Dr. Strange was nominated for the presidency of that year.

Dr. Bristowe delivered the address in Medicine, Mr. Jonathan Hutchinson that in Surgery, and Dr. Sinclair Coghill, of Ventnor, that in Obstetrics.

At the annual dinner of the Association, Dr. J. S. Billings responded to the toast of "the Army of the United States."

—

Owen County (Ky.) Medical Society.—The physicians of Owen County, Ky., organized in September a County Medical Society, and elected Dr. J. W. Johnson, President, and Dr. R. I. Peck, Secretary.

—

Vitiated Sea Breezes at Coney Island.—The summer residents of Coney Island, New York, having bitterly complained of the odours emanating from the fat rendering establishments on Barren Island, the Committee of the State Board of Health has visited the premises, and proposes to suppress the nuisance in question.

—

King's County Lunatic Asylum.—In his annual report upon the condition of the King's County Lunatic Asylum, in Flatbush, L. I., Dr. Shaw, the resident-physician, shows that, according to the statistics of the last two decades (from 1860 to 1880), the percentage of insane persons to the population of the county decreased from thirty-eight to twenty-nine per cent. Dr. Shaw has employed a system of non-restraint, whenever practicable, and reports excellent results from this method. During the year ending July 31, 1881, 428 patients were admitted

to the asylum, which now contains 868 inmates. Warden Murray, of the King's County Almshouse, reports that 3255 indigent persons were cared for during the year ending July 31, and that 673 still remain in the institution.

—

Resignation.—Dr. D. L. Schenck recently resigned the superintendency of the Flatbush Hospital, Brooklyn, N. Y., after occupying that position for seventeen years. Dr. H. O. Plimpton has been appointed temporary superintendent by the Commissioners of Charities and Correction.

—

Oleomargarine Redivivus.—A so-called "Oleomargarine Bill," in accordance with the requirements of which all oleomargarine exposed for sale was to be plainly marked, passed the New York Legislature, but was vetoed by Governor Cornell.

—

The New York Night Medical Service has now been in operation about a year. During that time five hundred calls have been made by its corps of physicians. It has been proposed to establish a day medical service which shall be conducted on a similar plan.

—

Poisoning by Gaultheria (Wintergreen).—Dr. M. L. FICHTNER, of Cranesville, Preston County, West Virginia, sends a report of the following cases of poisoning by oil of wintergreen: Rauhama C. and Malinda C., æt. respectively 14 and 15 years, drank, through mistake, on the 4th of August, 1881, the former about ℥j, and the latter about ℥ij, of the oil of *Gaultheria procumbens*. Both were seized with vertigo, weakness, hot skin, frequent pulse, cold sweats, laboured respiration, and dulness of hearing. In the latter there was also inability to speak, with cramp in epigastrium and convulsions. Warm water and salt were then given as an emetic, and followed by olive oil. In the former case olive oil was continued in half-teaspoonful doses three to four times a day for about ten days, and the patient recovered without any serious inconvenience. In the latter case, bromide of potassium, olive oil, and the decoction of slippery elm bark were used, with cold applications to the head. The patient died in about ten hours after the drinking from congestion of the brain and convulsions. The breath had a pungent odor, and the gaultheria was detected in the perspiration. The patients were treated, at first, by Dr. Daniel Fichtner, afterwards Drs. A. S. and M. L. Fichtner were called.

—

The Summer Home of the Children's Aid Society, at Bath, Long Island, which was opened on June 18th, has already entertained 2800 poor children from the tenement houses. About 200 children are received, every week, at the home, and are returned to the city, after a week's sojourn at the institution, to be succeeded by an equal number of new-comers.

—

Literary Notes.—In the *Archives Générales de Medecine* for September, Prof. DUPLAY gives an elaborate "critical review" on the treatment of aneurism by the elastic bandage entirely based on the able paper of Dr. Lewis A. Stimson, of New York, which appeared in the *American Journal of the Medical Sciences* for April last. Dr. Duplay translates and adopts as his own large portions of Dr. Stimson's paper together with his conclusions, but unkindly misspells his name and that of Dr. R. F. Weir, of New York, almost beyond recognition.

The "Atlanta Medical and Surgical Journal" has changed its name to *Atlanta Medical Register.*

G. P. Putnam's Sons announce a "Treatise on the Science and Practice of Medicine," by Dr. A. B. Palmer, Professor of Practice of Medicine in the University of Michigan; and have just published a volume on "Eczema and its Management," based on an analysis of 2500 cases, by Dr. L. Duncan Bulkley, of New York.

—

OBITUARY RECORD.—Died, at Buffalo, on the 28th of September, after a brief illness, aged 70 years, JAMES PLATT WHITE, M.D., Professor of Obstetrics in the University of Buffalo, and formerly Vice-President of the American Medical Association.

Dr. James P. White, a descendant of Peregrine White, one of the "Mayflower" colonists, was born in Austerlitz, Columbia Co., N. Y., March 14, 1811. He received his early education at the Middlebury Academy; his medical studies were commenced at the Fairfield Medical College, where he attended lectures during the years 1831–2–3, and at the Jefferson Medical College, Philadelphia, from which he graduated in 1834. He began professional practice in Buffalo immediately after graduation, and continued in active work almost until his death. Dr. White was one of the founders of the Medical Department of the University of Buffalo, where he occupied the Chair of Obstetrics and Gynæcology, and was in 1850 the first in this country, it is believed, to teach midwifery clinically. He was a prominent member of the American Medical Association, its Vice-President in 1870, and one of the Vice-Presidents of the International Medical Congress held in Philadelphia, in 1876, and a member of various medical societies. His contributions to medical literature during the last thirty years were numerous and on various subjects, and were mainly published in the *Buffalo Medical and Surgical Journal;* the papers which, however, served the most to establish his reputation were on "Chronic Inversion of the Uterus," published in the *American Journal of the Medical Sciences* in 1858 and 1874. He also was the author of the chapter on "Pregnancy" in Beck's *Medical Jurisprudence.*

Dr. White was a man of strong individuality and wide influence in both public and private life; he was possessed of great executive ability and public spirit, and leaves behind him many warm friends. As a specialist he acquired an extensive and enviable reputation.

—

CORRESPONDENCE.

1300 SPRUCE ST.,
PHILADELPHIA, Oct. 7, 1881.

MR. EDITOR: I have been asked by several of my medical friends for some comments on the case of President Garfield, which was, during its progress, I think, most uncourteously if not unprofessionally appropriated through the newspapers, by some surgeons, as their own. If they had had anything of importance to communicate, I am sure the gentlemen in charge would have given them respectful attention, for access to the White House and to the offices of those gentlemen by mail was not cut off. The case was a public one to members of the profession as citizens only, and doctors not being in possession of all the facts to make intelligent criticism, should have remembered that they were in no position to share "the credit of success or the blame of failure." Now since the death and the official publication of the results of the autopsy, the case has become public, both to professional and laymen, and doubtless its diagnosis, prognosis, and treatment are fair subjects for comment.

From Dr. Frank H. Hamilton's "Military Surgery," New York, 1865, page 338, I make the following extract:—

"In a few cases a ball has been known to pass through the side of the body of one of the vertebra, leaving a round hole or a lateral furrow, *without coming in contact with the spinal marrow or the bloodvessels. It is not probable that we shall be able to diagnosticate such a case clearly during the life of a patient, and if we were able to do so, we do not see what benefit could be derived from any surgical operation.*

In case, however, one of the transverse processes has been broken and sent inwards, although it is not likely to have penetrated the cavity of the abdomen, it may yet give rise to serious results by the *formation of an abscess in the bellies of the psoas muscles, which abscess may eventually make its way along between the fibres towards the groin, or may empty itself into the loose areolar tissue outside of the peritoneum.*"

The italics are mine. Could there possibly have been a more wonderful foreshadowing of the President's case? The fracture of the transverse process is replaced in the case in hand by the fracture of the body, which produced the abscess or channel along the psoas in precisely the same way as described by Dr. Hamilton. The description is perfect. The sinus or channel which was, in the words of the official report, supposed during life to be the track of the bullet, was practically an abscess and sinus caused by the disintegration of a vertebral body through gunshot, precisely as a chronic lumbar and psoas abscess is caused by the chronic disintegration of a vertebral body through disease. How truly Dr. Hamilton sets forth the difficulties of diagnosis, and how absolutely true he is as to surgical interference by operation, having for its object the getting of the missile, which, as the autopsy shows, was lying harmless, compared to the injuries it had inflicted. The diagnosis then was hard; but does it not seem, in the light of our present knowledge, that the deep significance of the nervous symptoms of the President immediately after the shooting, was lost sight of too early in the case? This, if so, was probably the result of the exciting surroundings, and of the fact that the doctors were more occupied in practical efforts to relieve these symptoms than in speculations as to their cause. They were attributed to injuries or impressions upon nerves of the lumbar plexus, instead of to direct shock to the cord itself. This view seemed to be confirmed by the fact that they promptly subsided under rest and other treatment. That temporary spinal shock does sometimes occur at once after an accident to the column, I will show further on by an actual recent case.

But those pains in the legs, those "tigers' claws," affected *both* sides; what would account for them so well as sudden injury of some kind to the spine? From their bilateral suddenness it is more reasonable to attribute them to direct action upon the centre, than to reflex transfer from the right to the left. The right side I assume exhibited them to a greater degree than the left, but the full force of the impact was received upon the right and was weakened upon the left. If I am not right and the pains were equal on both sides, then there is still stronger reason to refer the phenomena to a central origin.

I have read also, that at first there was hyperæsthesia of the genitals. If so, this, together with the "tigers' claws," pointed strongly to the spine. Some surgeons are sceptical about spinal shock. This summer, in July, Dr. Agnew assisted me in a case that confirms its occurrence.

A boy was shot in the back to the right of the third or fourth dorsal vertebra. He at once had characteristic symptoms in the legs of being

wounded in the spine. These soon disappeared. The course of the bullet was not readily made out at first, but the diagnosis was that the column was wounded without injury to the cord, as the symptoms were not continuous. After suppuration set in, the course of the ball was readily traced with a probe, and broken fragments of the vertebral processes were felt. The ball was not felt with a Nélaton or other probe. The patient was etherized. I made a large and deep incision through the muscles in the line of the wound, and removed some clothing and fragments of bone and finally a large bullet, which was lying immediately against the bony bridge of a vertebra. The boy recovered. Whether he will suffer from caries in the future remains to be seen. This boy certainly had spinal shock, without injury to the cord, for there was no remnant of paralysis when he was discharged from the hospital.[1]

But this case is very different from the President's in this, that it was amenable to operation, and we knew about where the ball was. Also here, the ball would have produced great future mischief. In the President's case it did its damage and then hid. If such difficulty occurred in the hunt for it as is stated at the autopsy, imagine the horror of a like attempt on a live man. How long would he have lived? He had better have been killed at a blow.

A surgeon who has *lived* in an accident hospital and receives cases day and night, immediately after injury, gets into the habit of making "snap" diagnoses. It is really not the presumption of ignorance, but it is the quick application of knowledge gained by experience. In nineteen cases out of twenty the "snap" is right; often he who deliberates is lost. Now excuse the egotism, for I have abundant proof of what I say, and I say it for the credit of diagnosis, "snap" though it be. At once, upon reading the accounts of the leg pains and the "tigers' claws," I said to a medical friend, and I have no doubt that many other hospital men said the same thing, "the President is shot in the spinal column." But after the diagnosis was given to the public stating that the direction of the ball was downward and forward, through the liver, and into the anterior wall of the abdomen, I came to the conclusion that in this case the "snap" had failed.

The question of the duty of the consulting surgeons when they first went to Washington has been freely discussed. Should they have re-opened and re-examined the wound with probes and fingers? I am assuming that they did not do so, and they were right. A hospital chief, if he has confidence in his residents or assistants, and knows them to be experienced and ready, takes what they say about serious cases which will not tolerate officious disturbance. He recognizes the "snap" if the other symptoms confirm it. For example, the chief visits the hospital on his regular rounds. The resident says, "Doctor, here's a man who was brought in last night shot in the abdomen. He was greatly shocked; I examined him and passed my finger directly into the cavity; I removed some pieces of clothing; I can feel the bullet nowhere under the skin about the whole body; I searched carefully; I have dressed the wound and given some opium; he is now quiet and free from pain." The surgeon looks at the patient, sees that his general symptoms confirm the diagnosis, and that his wounds are carefully dressed. He probably re-examines the body

[1] Whilst reading proof of this article, October 18th, this boy walked into my office, having been kindly sent to me, by Dr. W. C. Cox, of the Out-Department of the Hospital. He was perfectly well in every respect.

externally, but if he is a wise man he says practically "hands off, we will await results and act accordingly."

Many a life has been saved by this course; many a one has been lost by deviating from it. I question if one has ever been saved, in the kind of case now under notice, by deviating from it. Now if a surgeon can so treat those who are *under* him, how much more is he bound (unless he sees something positively and absolutely wrong), to receive the statements of his peers, especially when outward appearances seem to confirm them. I question, moreover, whether any more light whatever would have been thrown on the President's case by further exploration at the time when the consulting surgeons made their first visit? By that time, the spinal symptoms had disappeared, or were very much alleviated. Inflammation through swelling of the denser tissues, muscular and fibrous, of the true track of the ball had doubtless closed it. The finger or probes would have passed easily where other fingers and probes had already been, and there would have been almost certainly a positive confirmation of the results of the first examination. When I study the autopsy more closely, I think that this would almost to a certainty have been the case. If I understand the description and the drawing, the ball entered at a place which, if it had had consciousness and an intent to deceive, could not have been better selected in the whole body. It entered "three and a half inches to the right of the vertebral spines," therefore its course began to the right of the psoas mass. Instead of going forward, it traversed the circle of the body transversely, after fracturing the eleventh rib, and went directly on in the direction of a chord of an arc of that circle. It entered the post-peritoneal space and thus penetrated the posterior wall of the abdomen, without opening the peritoneum. It then continued on into the muscular mass, separating the longitudinal fibres, which may have closed behind it. The finger was passed into the wound and also probes. These went readily on in the space mentioned, and the true course was missed. I have no doubt the depending liver, or it may be the kidney, was felt. The wound was one to deceive the very elect. The influence of the inner loin muscles in concealing injuries and diseases of the lumbar vertebra is well recognized. The post-mortem report speaks of the dilated track of the ball, but this dilatation was owing to subsequent changes. I am ignorant of any other explanation of the position taken by fingers and probes, than that I have given.

It is a mistake to suppose the spine escaped attention in the case. Dr. Agnew assures me, that when he operated for the relief of the lumbar abscess, he carefully searched the transverse processes and all of the spine he could feel, and felt nothing wrong. The injury to it was beyond his fingers, and a wise caution here forbade the use of instruments. How truly Dr. Hamilton's remarks are illustrated by this experience. Moreover, by the incisions Dr. Agnew made, which he tells me were carefully planned for drainage, the whole line of the true wound, as well as the mistaken sinus, had full outlet.

The abscess which was found after death, bounded by the liver, the transverse colon, and the transverse meso-colon, for anatomical reasons, was shut off from communication with the wound, and of course was not drained. In the words of the official report, "no communication could be detected between it and the wound." No method of diagnosis occurs to me by which its existence could have been determined during life, unless it had got far enough to cause posterior or anterior bulging.

It was an abscess, arising either from peritoneal inflammation through contiguity or it was a septic deposit.

The case really was one to diagnosticate more by the application of anatomy and physiological and pathological knowledge, than by direct methods. In the light of the autopsy, everything is explained. By the theory of the wound during life, almost nothing.

There were the pains in the limbs and the "tigers' claws." There was most profound depression and a pulse and temperature record which, after the liver theory was abandoned, the accepted wound, at most a severe flesh one, was insufficient to account for. There was the origin of the thoracic duct with its receptaculum chyli right in the line of the wound; hence, the rapid emaciation, and the other nutritive disabilities, further explained by disturbance of the sympathetic trunks and ganglia. There were the radicles of the vena azygos, bathed in the corruption of rotting vertebra, and hence the septicæmia, and there was the abscess and sinus, running toward the groin, a result of the rotting vertebra and not of the ball. What good could it have done to have cut for the bullet after its first mischief? It was then but a small factor in the troubles.

As to the liver, there are recoveries from wounds of it, but they are rare. Between twenty and thirty of such recoveries are reported I think in the surgery of the war. How many even of these were mistakes as to diagnosis? During my last term at the hospital, an old soldier, very peculiarly and deeply jaundiced, fractured his thigh. He told us that the jaundice was an old affair, that he had been shot through the liver in the war, and showed the external scar. He became very sick and died. The liver was most carefully examined, but there was no mark of a wound about it, nor in it. Serious wounds of the liver generally kill promptly by hemorrhage. Hundreds must be killed in this way in battle. On the other hand, recovery may take place and a bullet (strange as it may seem) may become completely encysted in the organ. Dr. Owens, now resident in the Pennsylvania Hospital, has a bullet with the encysting capsule around it which he took from the liver of an old fellow who died in the almshouse from some other cause. It must have laid there for many years.

As to the treatment of the President's case, it was in the light of the autopsy most fortunate. A very valuable life was prolonged beyond all reasonable hope. From a letter I had from Dr. Agnew, dated the 23d of August, 1881, which was confidential then but open now, I know how fully he appreciated the profound gravity of the case, and took an almost hopeless view of it, but still he with his colleagues fought it out nobly. When we come to think of it, it may be a mercy that an exact diagnosis was not made. The temptation to do something more than was done, if it had been made, would have been very great. Outside and inconsiderate pressure would have been clamorous. Whether it would have moved the steady heads in charge, I do not know; but if it had, I am confident the President would have been ready for his grave on the day of the operation. Who can picture the political results that might have followed? Now the perturbing elements have been calmed, and all is peace.

Much has been said about antiseptic treatment in the case. It was practised, I believe, to a very great extent. Its *practice* is grand, except the spray; I heartily agree with the German surgeon who said "fort mit dem spray." Could there be a better commentary on the *unproved theory* of antiseptic surgery than the President's case? Against its theory, or at

least the effect of it on many minds, viz., that all sources of contamination producing septic poisoning come from without, I earnestly protest. I have too much respect for Mr. Lister to think that he believes what the extremists among his disciples teach.

The influence of such teaching on the rising generation of physicians and surgeons is bad, in this, that it leads to narrow views and interferes with clear diagnosis. It leads outwardly too much, for contamination comes from within, I believe, more frequently than from without. Was not the decaying vertebra in the President's case enough to account for the septicæmia?

To get all the rats out and then stop the hole with poison and stuffing is a good thing, but to poison and plug the hole and leave the rats in, is a very bad thing. They only undermine and make other holes. A narrow antiseptist looks around the room instead of at the patient, whereas, he should look at both and give due weight to all septic possibilities.

Discussion is now going on as to whether the President's wound was mortal or not. What is mortal? Essentially mortal wounds are extremely limited. A sweep through a certain portion of the medulla oblongata, which is itself a small organ, or a wound opening the aorta, may be instanced as examples. Haller's tripod of life was the heart, the lungs, and the brain. One leg of this tripod gone, the rest falls. The leg must be thoroughly undermined, or else injured in a particular part. Many people get well of wounds of the brain and lungs. Recoveries occur from injuries to the muscular substance of the heart without opening its cavities. Foreign bodies lie imbedded in that substance for years. I saw a large needle taken out of the heart of a negro in the dissecting-room, which must have been there for a very long time, and had nothing to do with his death. Now, setting aside everything else, what was the immediate cause of the President's death? It was from what, in extent of tissue involved, was the smallest serious feature of his injuries. It was the rupture of a traumatic aneurism of the splenic artery! I know of no method in science that would surely locate such an aneurism. If it were located, I know of no measure that would stop its progress. That progress is steadily on to rupture. Anatomy surrounds it with no special sustaining structures. That rupture was essentially fatal, and so with other injuries that might have killed, this one positively did kill.

Such an improbable course as the following was possible in the President's case. The development of the aneurism might have been slower. The bullet was already encysted. The injured vertebra might have cast off its decaying debris, and it, together with the rest of the wound, might have healed. The President might have been pronounced well, and even have resumed his duties. Some day, suddenly, an agonizing cry of pain would have escaped him, and he would have fallen and died as though he were shot a second time! No one would have known the cause until an autopsy revealed the ruptured aneurism. It is but a piece of special pleading to say the wound was not mortal.

WILLIAM HUNT,
Senior Surgeon to the Pennsylvania Hospital.

To Readers and Correspondents.—The Editor will be happy to receive early intelligence of local events of general medical interest, or which it is desirable to bring to the notice of the profession. Local papers containing reports or news items should be marked.

HENRY C. LEA'S SON & CO.'S

(LATE HENRY C. LEA)

CLASSIFIED CATALOGUE

OF

MEDICAL AND SURGICAL PUBLICATIONS,

In asking the attention of the profession to the works advertised in the following pages, the publishers would state that no pains are spared to secure a continuance of the confidence earned for the publications of the house by their careful selection and accuracy and finish of execution.

The large number of inquiries received from the profession for a finer class of bindings than is usually placed on medical books has induced us to put certain of our standard publications in half Russia, and that the growing taste may be encouraged, the prices have been fixed at so small an advance over the cost of sheep, as to place it within the means of all to possess a library that shall have attractions as well for the eye as for the mind of the reading practitioner.

The printed prices are those at which books can generally be supplied by booksellers throughout the United States, who can readily procure for their customers any works not kept in stock. Where access to bookstores is not convenient, books will be sent by mail post-paid on receipt of the price, and as the limit of mailable weight has been removed, no difficulty will be experienced in obtaining through the post-office any work in this catalogue. No risks, however, are assumed either on the money or on the books, and no publications but our own are supplied, so that gentlemen will in most cases find it more convenient to deal with the nearest bookseller.

HENRY C. LEA'S SON & CO.

Nos. 706 and 708 SANSOM ST., PHILADELPHIA, November, 1881.

INCREASED INDUCEMENT FOR SUBSCRIBERS TO

THE AMERICAN JOURNAL OF THE MEDICAL SCIENCES.

TWO MEDICAL JOURNALS, containing nearly 2000 LARGE PAGES,

Free of Postage, for FIVE DOLLARS Per Annum.

TERMS FOR 1881.

THE AMERICAN JOURNAL OF THE MEDICAL SCIENCES, published quarterly (1150 pages per annum), with
THE MEDICAL NEWS AND ABSTRACT, monthly (768 pp. per annum),
} Five Dollars per annum, in advance.

SEPARATE SUBSCRIPTIONS TO

THE AMERICAN JOURNAL OF THE MEDICAL SCIENCES, when not paid for in advance, Five Dollars.

THE MEDICAL NEWS AND ABSTRACT, free of postage, in advance, Two Dollars and a Half.

*** Advance paying subscribers can obtain at the close of the year cloth covers, gilt-lettered, for each volume of the Journal (two annually), and of the News and Abstract (one annually), free by mail, by remitting ten cents for each cover.

It will thus be seen that for the moderate sum of FIVE DOLLARS in advance, the subscriber will receive, free of postage, the equivalent of four large octavo volumes, stored with the choicest matter, original and selected, that can be furnished by the medical literature of both hemispheres. Thus taken together, the "JOURNAL" and the "NEWS AND ABSTRACT" combine the advantages of the elaborate preparation that can be devoted to the Quarterly with the prompt conveyance of intelligence by the Monthly; while, the whole being under a single editorial supervision, the subscriber is secured against the duplication of matter inevitable when periodicals from different sources are taken together.

The periodicals thus offered at this unprecedented rate are universally known for

their high professional standing.

I.

THE AMERICAN JOURNAL OF THE MEDICAL SCIENCES,

EDITED BY I. MINIS HAYS, M.D.,

for more than half a century has maintained its position in the front rank of the medical literature of the world. Cordially supported by the profession of America, it circulates wherever the language is read, and is universally regarded as the national exponent of American medicine—a position to which it is entitled by the distinguished names from every section of the Union which are to be found among its collaborators.* It is issued quarterly, in January, April, July, and October, each number containing about three hundred octavo pages, appropriately illustrated wherever necessary. A large portion of this space is devoted to Original Communications, embracing papers from the most eminent members of the profession throughout the country.

Following this is the REVIEW DEPARTMENT, containing extended reviews by competent writers of prominent new works and topics of the day, together with numerous elaborate Analytical and Bibliographical Notices, giving a fairly complete survey of medical literature.

Then follows the QUARTERLY SUMMARY OF IMPROVEMENTS AND DISCOVERIES IN THE MEDICAL SCIENCES, classified and arranged under different heads, and furnishing a digest of medical progress, abroad and at home.

Thus during the year 1880 the "JOURNAL" contained 67 Original Communications, mostly elaborate in character, 170 Reviews and Bibliographical Notices, and 147 articles in the Quarterly Summaries, illustrated with 47 wood engravings.

That the efforts thus made to maintain the high reputation of the "JOURNAL" are successful, is shown by the position accorded to it in both America and Europe as the leading organ of medical progress:—

This is universally acknowledged as the leading American Journal, and has been conducted by Dr. Hays alone until 1869, when his son was associated with him. We quite agree with the critic, that this Journal is second to none in the language, and cheerfully accord to it the first place, for nowhere shall we find more able and more impartial criticism, and nowhere such a repertory of able original articles. Indeed, now that the "British and Foreign Medico-Chirurgical Review" has terminated its career, the American Journal stands without a rival.—*London Med. Times and Gazette*, Nov. 24, 1877.

The best medical journal on the continent.—*Boston Med. and Surg. Journal*, April, 1879.

The present number of the American Journal is an exceedingly good one, and gives every promise of maintaining the well-earned reputation of the review. Our venerable contemporary has our best wishes, and we can only express the hope that it may continue its work with as much vigor and excellence for the next fifty years as it has exhibited in the past.—*London Lancet*, Nov. 24, 1877.

The Philadelphia Medical and Physical Journal issued its first number in 1820, and, after a brilliant career, was succeeded in 1827 by the American Journal of the Medical Sciences, a periodical of world-wide reputation; the ablest and one of the oldest periodicals in the world—a journal which has an unsullied record.—*Gross's History of American Med. Literature* 1876.

The best medical journal ever published in Europe or America.—*Va. Med. Monthly*, May, 1879.

It is universally acknowledged to be the leading American medical journal, and, in our opinion, is second to none in the language.—*Boston Med. and Surg. Journal*, Oct. 1877.

This is the medical journal of our country to which the American physician abroad will point with the greatest satisfaction, as reflecting the state of medical culture in his country. For a great many years it has been the medium through which our ablest writers have made known their discoveries and observations.—*Address of L. P. Yandell, M.D., before International Med. Congress*, Sept. 1876.

And that it was specifically included in the award of a medal of merit to the Publishers in the Vienna Exhibition in 1873.

The subscription price of the "AMERICAN JOURNAL OF THE MEDICAL SCIENCES" has never been raised during its long career. It is still FIVE DOLLARS per annum; and when paid for in advance, the subscriber receives in addition the "MEDICAL NEWS AND ABSTRACT," making in all nearly 2000 large octavo pages per annum, free of postage.

II.

THE MEDICAL NEWS AND ABSTRACT.

Thirty-eight years ago the "MEDICAL NEWS" was commenced as a monthly to convey to the subscribers of the "AMERICAN JOURNAL" the clinical instruction and

* Communications are invited from gentlemen in all parts of the country. Articles inserted by the Editor are liberally paid for by the publishers.

current information which could not be accommodated in the Quarterly. It consisted of sixteen pages of such matter, together with sixteen more known as the Library Department and devoted to the publishing of books. With the increased progress of science, however, this was found insufficient, and some years since another periodical, known as the "MONTHLY ABSTRACT," was started, and was furnished at a moderate price to subscribers to the "AMERICAN JOURNAL." These two monthlies have been consolidated, under the title of "THE MEDICAL NEWS AND ABSTRACT," and are furnished *free of charge* in connection with the "AMERICAN JOURNAL."

The "NEWS AND ABSTRACT" consists of 64 pages monthly, in a neat cover. It contains a CLINICAL DEPARTMENT in which will be continued the series of ORIGINAL AMERICAN CLINICAL LECTURES, by gentlemen of the highest reputation throughout the United States, together with a choice selection of foreign Lectures and Hospital Notes and Gleanings. Then follows the MONTHLY ABSTRACT, systematically arranged and classified, and presenting five or six hundred articles yearly; and each number concludes with an EDITORIAL and a NEWS DEPARTMENT, giving current professional intelligence, domestic and foreign, the whole fully indexed at the close of each volume, rendering it of permanent value for reference.

As stated above, the subscription price to the "NEWS AND ABSTRACT" is TWO DOLLARS and a HALF per annum, invariably in advance, at which rate it ranks as one of the cheapest medical periodicals in the country. But it is also furnished, free of all charge, in commutation with the "AMERICAN JOURNAL OF THE MEDICAL SCIENCES," to all who remit FIVE DOLLARS in advance, thus giving to the subscriber, for that very moderate sum, a complete record of medical progress throughout the world, in the compass of about two thousand large octavo pages.

In this effort to furnish so large an amount of practical information at a price so unprecedentedly low, and thus place it within the reach of every member of the profession, the publishers confidently anticipate the friendly aid of all who feel an interest in the dissemination of sound medical literature. They trust, especially, that the subscribers to the "AMERICAN MEDICAL JOURNAL," will call the attention of their acquaintances to the advantages thus offered, and that they will be sustained in the endeavor to permanently establish medical periodical literature on a footing of cheapness never heretofore attempted.

PREMIUM FOR OBTAINING NEW SUBSCRIBERS TO THE "JOURNAL."

Any gentleman who will remit the amount for two subscriptions for 1881, one of which at least must be for a *new subscriber*, will receive as a PREMIUM, free by mail, a copy of any one of the following recent works:—

"SEILER ON THE THROAT" (see p. 19),
"BARNES'S MANUAL OF MIDWIFERY" (see p. 24),
"BROWNE ON THE USE OF THE OPHTHALMOSCOPE" (see p. 29),
"FLINT'S ESSAYS ON CONSERVATIVE MEDICINE" (see p. 15),
"STURGES'S CLINICAL MEDICINE" (see p. 15),
"TANNER'S CLINICAL MANUAL" (see p. 5),
"WEST ON NERVOUS DISORDERS OF CHILDREN" (see p. 21).

*** Gentlemen desiring to avail themselves of the advantages thus offered will do well to forward their subscriptions at an early day, in order to insure the receipt of complete sets for the year 1881.

☞ The safest mode of remittance is by bank check or postal money order, drawn to the order of the undersigned. Where these are not accessible, remittances for the "JOURNAL" may be made at the risk of the publishers, by forwarding in REGISTERED letters. Address,

HENRY C. LEA'S SON & CO., Nos. 706 and 708 Sansom St., Phila., Pa.

DUNGLISON (ROBLEY), M.D.,

Late Professor of Institutes of Medicine in Jefferson Medical College, Philadelphia.

MEDICAL LEXICON; A DICTIONARY OF MEDICAL SCIENCE:

Containing a concise explanation of the various Subjects and Terms of Anatomy, Physiology, Pathology, Hygiene, Therapeutics, Pharmacology, Pharmacy, Surgery, Obstetrics, Medical Jurisprudence and Dentistry. Notices of Climate and of Mineral Waters; Formulæ for Officinal, Empirical and Dietetic Preparations; with the Accentuation and Etymology of the Terms, and the French and other Synonymes; so as to constitute a French as well as English Medical Lexicon. A New Edition. Thoroughly Revised, and very greatly Modified and Augmented. By RICHARD J. DUNGLISON, M.D. In one very large and handsome royal octavo volume of over 1100 pages. Cloth, $6 50; leather, raised bands, $7 50; half Russia, $8. (*Lately Issued.*)

The object of the author from the outset has not been to make the work a mere lexicon or dictionary of terms, but to afford, under each, a condensed view of its various medical relations, and thus to render the work an epitome of the existing condition of medical science. Starting with this view, the immense demand which has existed for the work has enabled him, in repeated revisions, to augment its completeness and usefulness, until at length it has attained the position of a recognized and standard authority wherever the language is spoken.

Special pains have been taken in the preparation of the present edition to maintain this enviable reputation. During the ten years which have elapsed since the last revision, the additions to the nomenclature of the medical sciences have been greater than perhaps in any similar period of the past, and up to the time of his death the author labored assiduously to incorporate everything requiring the attention of the student or practitioner. Since then, the editor has been equally industrious, so that the additions to the vocabulary are more numerous than in any previous revision. Especial attention has been bestowed on the accentuation, which will be found marked on every word. The typographical arrangement has been much improved, rendering reference much more easy, and every care has been taken with the mechanical execution. The work has been printed on new type, small but exceedingly clear, with an enlarged page, so that the additions have been incorporated with an increase of but little over a hundred pages, and the volume now contains the matter of at least four ordinary octavos.

A book well known to our readers, and of which every American ought to be proud. When the learned author of, the work passed away, probably all of us feared lest the book should not maintain its place in the advancing science whose terms it defines. Fortunately, Dr. Richard J. Dunglison, having assisted his father in the revision of several editions of the work, and having been, therefore, trained in the methods and imbued with the spirit of the book, has been able to edit it, not in the patchwork manner so dear to the heart of book editors, so repulsive to the taste of intelligent book readers, but to edit it as a work of the kind should be edited—to carry it on steadily, without jar or interruption, along the grooves of thought it has travelled during its lifetime. To show the magnitude of the task which Dr. Dunglison has assumed and carried through, it is only necessary to state that more than six thousand new subjects have been added in the present edition.—*Phila. Med. Times*, Jan. 3, 1874.

About the first book purchased by the medical student is the Medical Dictionary. The lexicon explanatory of technical terms is simply a *sine qua non*. In a science so extensive, and with such collaterals as medicine, it is as much a necessity also to the practising physician. To meet the wants of students and most physicians, the dictionary must be condensed while comprehensive, and practical while perspicacious. It was because Dunglison's met these indications that it became at once the dictionary of general use wherever medicine was studied in the English language. In no former revision have the alterations and additions been so great. More than six thousand new subjects and terms have been added. The chief terms have been set in black letter, while the derivatives follow in small caps; an arrangement which greatly facilitates reference. We may safely confirm the hope ventured by the editor "that the work, which possesses for him a filial as well as an individual interest, will be found worthy a continuance of the position so long accorded to it as a standard authority."—*Cincinnati Clinic*, Jan. 10, 1874.

It has the rare merit that it certainly has no rival in the English language for accuracy and extent of references.—*London Medical Gazette*.

As a standard work of reference, as one of the best, if not the very best, medical dictionary in the English language, Dunglison's work has been well known for about forty years, and needs no words of praise on our part to recommend it to the members of the medical, and, likewise, of the pharmaceutical profession. The latter especially are in need of such a work, which gives ready and reliable information on thousands of subjects and terms which they are liable to encounter in pursuing their daily avocations, but with which they cannot be expected to be familiar. The work before us fully supplies this want.—*Am. Journ. of Pharm.*, Feb. 1874.

A valuable dictionary of the terms employed in medicine and the allied sciences, and of the relations of the subjects treated under each head. It reflects great credit on its able American author, and well deserves the authority and popularity it has obtained.—*British Med. Journ.*, Oct. 31, 1874.

Few works of this class exhibit a grander monument of patient research and of scientific lore. The extent of the sale of this lexicon is sufficient to testify to its usefulness, and to the great service conferred by Dr. Robley Dunglison on the profession, and indeed on others, *by its issue*.—*London Lancet*, May 13, 1875.

HOBLYN (RICHARD D.), M.D.

A DICTIONARY OF THE TERMS USED IN MEDICINE AND THE COLLATERAL SCIENCES.

Revised, with numerous additions, by ISAAC HAYS, M.D., Editor of the "American Journal of the Medical Sciences." In one large royal 12mo. volume of over 500 double-columned pages; cloth, $1 50; leather, $2 00

It is the best book of definitions we have, and ought always to be upon the student's table.—*Southern Med. and Surg. Journal.*

RODWELL (G. F.), F.R.A.S., &c.

A DICTIONARY OF SCIENCE:

Comprising Astronomy, Chemistry, Dynamics, Electricity, Heat, Hydrodynamics, Hydrostatics, Light, Magnetism, Mechanics, Meteorology, Pneumatics, Sound and Statics. Preceded by an Essay on the History of the Physical Sciences. In one handsome octavo volume of 694 pages, with many illustrations: cloth, $5.

A *CENTURY OF AMERICAN MEDICINE*, 1776–1876. By Doctors E. H. Clarke, H. J. Bigelow, S. D. Gross, T. G. Thomas and J. S. Billings. In one very handsome 12mo. volume of about 350 pages: cloth, $2 25.

This work appeared in the pages of the American Journal of the Medical Sciences during the year 1876. As a detailed account of the development of medical science in America, by gentlemen of the highest authority in their respective departments, the profession will no doubt welcome it in a form adapted for preservation and reference.

NEILL (JOHN), M.D., and SMITH (FRANCIS G.), M.D.,
Prof. of the Institutes of Medicine in the Univ. of Penna.

AN ANALYTICAL COMPENDIUM OF THE VARIOUS BRANCHES OF MEDICAL SCIENCE; for the Use and Examination of Students. A new edition, revised and improved. In one very large and handsomely printed royal 12mo. volume, of about one thousand pages, with 374 wood-cuts, cloth, $4; strongly bound in leather, with raised bands, $4 75.

HARTSHORNE (HENRY), M.D.,
Professor of Hygiene in the University of Pennsylvania.

A CONSPECTUS OF THE MEDICAL SCIENCES; containing Handbooks on Anatomy, Physiology, Chemistry, Materia Medica, Practical Medicine, Surgery and Obstetrics. Second Edition, thoroughly revised and improved. In one large royal 12mo. volume of more than 1000 closely printed pages, with 477 illustrations on wood. Cloth, $4 25; leather, $5 00.

We can say with the strictest truth that it is the best work of the kind with which we are acquainted. It embodies in a condensed form all recent contributions to practical medicine, and is therefore useful to every busy practitioner throughout our country, besides being admirably adapted to the use of students of medicine. The book is faithfully and ably executed.—*Charleston Med. Journ.*, April, 1875.

The work is intended as an aid to the medical student, and as such appears to admirably fulfil its object by its excellent arrangement, the full compilation of facts, the perspicuity and terseness of language, and the clear and instructive illustrations in some parts of the work.—*American Journ. of Pharmacy*, Philadelphia, July, 1874.

The volume will be found useful, not only to students, but to many others who may desire to refresh their memories with the smallest possible expenditure of time.—*N. Y. Med. Journal*, Sept. 1874.

The student will find this the most convenient and useful book of the kind on which he can lay his hand.—*Pacific Med. and Surg. Journ.*, Aug. 1874.

This is the best book of its kind that we have ever examined. It is an honest, accurate, and concise compend of medical sciences, as fairly as possible representing their present condition. The changes and the additions have been so judicious and thorough as to render it, so far as it goes, entirely trustworthy. If students must have a conspectus, they will be wise to procure that of Dr. Hartshorne.—*Detroit Rev. of Med. and Pharm.*, Aug. 1874.

The work before us has many redeeming features not possessed by others, and is the best we have seen. Dr. Hartshorne exhibits much skill in condensation. It is well adapted to the physician in active practice, who can give but limited time to the familiarizing of himself with the important changes which have been made since he attended lectures. The manual of physiology has also been improved and gives the most comprehensive view of the latest advances in the science possible in the space devoted to the subject. The mechanical execution of the book leaves nothing to be wished for.—*Peninsular Journal of Medicine*, Sept. 1874.

After carefully looking through this conspectus, we are constrained to say that it is the most complete work, especially in its illustrations, of its kind that we have seen.—*Cincinnati Lancet*, Sept. 1874.

The favor with which the first edition of this Compendium was received, was an evidence of its various excellences. The present edition bears evidence of a careful and thorough revision. Dr. Hartshorne possesses a happy faculty of seizing upon the salient points of each subject, and of presenting them in a concise and yet perspicuous manner.—*Leavenworth Med. Herald*, Oct. 1874

LUDLOW (J. L.), M.D.

A MANUAL OF EXAMINATIONS upon Anatomy, Physiology, Surgery, Practice of Medicine, Obstetrics, Materia Medica, Chemistry, Pharmacy and Therapeutics. To which is added a Medical Formulary. Third edition, thoroughly revised and greatly extended and enlarged. With 370 illustrations In one handsome royal 12mo. volume of 816 large pages. Cloth, $3 25; leather, $3 75.

The arrangement of this volume in the form of question and answer renders it especially suitable for the office examination of students, and for those preparing for graduation.

TANNER (THOMAS HAWKES), M.D., &c.

A MANUAL OF CLINICAL MEDICINE AND PHYSICAL DIAGNOSIS. Third American from the Second London Edition. Revised and Enlarged by TILBURY FOX, M. D., Physician to the Skin Department in University College Hospital, London, &c. In one neat volume, small 12mo., of about 375 pages, cloth, $1 50.

*** On page 3, it will be seen that this work is offered as a premium for procuring new subscribers to the "AMERICAN JOURNAL OF THE MEDICAL SCIENCES."

GRAY (HENRY), F.R.S.,

Lecturer on Anatomy at St. George's Hospital, London.

ANATOMY, DESCRIPTIVE AND SURGICAL.

The Drawings by H. V. CARTER, M.D., and Dr. WESTMACOTT. The Dissections jointly by the AUTHOR and Dr. CARTER. With an Introduction on General Anatomy and Development by T HOLMES, M.A., Surgeon to St. George's Hospital. A new American. from the Eighth enlarged and improved London edition. To which is added the Second American from the latest English Edition of "LANDMARKS, MEDICAL AND SURGICAL," by LUTHER HOLDEN, F.R.C.S., author of "Human Osteology," "A Manual of Dissections," etc. In one magnificent imperial octavo volume of 983 pages, with 522 large and elaborate engravings on wood. Cloth, $6; leather, raised bands, $7; half Russia, $7 50.

The author has endeavored in this work to cover a more extended range of subjects than is customary in the ordinary text-books, by giving not only the details necessary for the student, but also the application of those details in the practice of medicine and surgery, thus rendering it both a guide for the learner, and an admirable work of reference for the active practitioner. The engravings form a special feature in the work, many of them being the size of nature, nearly all original, and having the names of the various parts printed on the body of the cut, in place of figures of reference, with descriptions at the foot. They thus form a complete and splendid series, which will greatly assist the student in obtaining a clear idea of Anatomy, and will also serve to refresh the memory of those who may find in the exigencies of practice the necessity of recalling the details of the dissecting room; while combining, as it does, a complete Atlas of Anatomy, with a thorough treatise on systematic, descriptive and applied Anatomy, the work will be found of essential use to all physicians who receive students in their offices, relieving both preceptor and pupil of much labor in laying the groundwork of a thorough medical education.

Since the appearance of the last American Edition, the work has received three revisions at the hands of its accomplished editor, Mr. Holmes, who has sedulously introduced whatever has seemed requisite to maintain its reputation as a complete and authoritative standard text-book and work of reference. Still further to increase its usefulness, there has been appended to it the recent work by the distinguished anatomist, Mr. Luther Holden—"Landmarks, Medical and Surgical"—which gives in a clear, condensed and systematic way, all the information by which the practitioner can determine from the external surface of the body the position of internal parts. Thus complete, the work, it is believed, will furnish all the assistance that can be rendered by type and illustration in anatomical study. No pains have been spared in the typographical execution of the volume, which will be found in all respects superior to former issues. Notwithstanding the increase of size, amounting to over 100 pages and 57 illustrations, it will be kept, as heretofore, at a price rendering it one of the cheapest works ever offered to the American profession.

The recent work of Mr. Holden, which was noticed by us on p. 58 of this volume, has been added as an appendix, so that, altogether, this is the most practical and complete anatomical treatise available to American students and physicians. The former finds in it the necessary guide in making dissections; a very comprehensive chapter on minute anatomy; and about all that can be taught him on general and special anatomy; while the latter, in its treatment of each region from a surgical point of view, and in the valuable addition of Mr. Holden, will find all that will be essential to him in his practice.—*New Remedies*, Aug 1878.

This work is as near perfection as one could possibly or reasonably expect any book intended as a text-book or a general reference book on anatomy to be. The American publisher deserves the thanks of the profession for appending the recent work of Mr. Holden, "*Landmarks, Medical and Surgical*," which has already been commended as a separate book. The latter work—treating of topographical anatomy—has become an essential to the library of every intelligent practitioner. We know of no book that can take its place, written as it is by a most distinguished anatomist. It would be simply a waste of words to say anything further in praise of Gray's Anatomy, the text-book in almost every medical college in this country, and the daily reference book of every practitioner who has occasion to consult his books on anatomy. The work is simply indispensable, especially this present American edition.—*Va. Med. Monthly*, Sept. 1878.

The addition of the recent work of Mr. Holden, as an appendix, renders this the most practical and complete treatise available to American students, who find in it a comprehensive chapter on minute anatomy, about all that can be taught on general and special anatomy, while its treatment of each region, from a surgical point of view, in the valuable section by Mr. Holden, is all that will be essential to them in practice.—*Ohio Medical Recorder*, Aug. 1878.

It is difficult to speak in moderate terms of this new edition of "Gray." It seems to be as nearly perfect as it is possible to make a book devoted to any branch of medical science. The labors of the eminent men who have successively revised the eight editions through which it has passed, would seem to leave nothing for future editors to do. The addition of Holden's "Landmarks" will make it as indispensable to the practitioner of medicine and surgery as it has been heretofore to the student. As regards completeness, ease of reference, utility, beauty, and cheapness, it has no rival. No student should enter a medical school without it; no physician can afford to have it absent from his library.—*St. Louis Clin. Record*, Sept. 1878.

ALSO FOR SALE SEPARATE—

HOLDEN (LUTHER), F.R.C.S.,

Surgeon to St. Bartholomew's and the Foundling Hospitals.

LANDMARKS, MEDICAL AND SURGICAL.

Second American, from the Latest Revised English Edition, with additions by W. W. KEEN, M.D., Prof. of Artistic Anatomy in the Penna. Academy of the Fine Arts, formerly Lecturer on Anatomy in the Phila. School of Anatomy. In one handsome 12mo. volume, of about 140 pages. Cloth, $1.00. (*Just Ready.*)

HEATH (CHRISTOPHER), F.R.C.S.,

Teacher of Operative Surgery in University College, London.

PRACTICAL ANATOMY: A Manual of Dissections.

From the Second revised and improved London edition. Edited, with additions, by W. W. KEEN, M. D., Lecturer on Pathological Anatomy in the Jefferson Medical College, Philadelphia. In one handsome royal 12mo. volume of 578 pages, with 247 illustrations. Cloth, $3 50; leather, $4 00.

ALLEN (HARRISON), M.D.
Professor of Physiology in the Univ. of Pa.

A SYSTEM OF HUMAN ANATOMY: INCLUDING ITS MEDICAL and Surgical Relations. For the Use of Practitioners and Students of Medicine. With an Introductory Chapter on Histology. By E. O. SHAKESPEARE, M D., Ophthalmologist to the Phila. Hosp. In one large and handsome quarto volume, with several hundred original illustrations on lithographic plates, and numerous wood-cuts in the text. (*Shortly.*)

In this elaborate work, which has been in active preparation for several years, the author has sought to give, not only the details of descriptive anatomy in a clear and condensed form, but also the practical applications of the science to medicine and surgery. The work thus has claims upon the attention of the general practitioner, as well as of the student, enabling him not only to refresh his recollections of the dissecting room, but also to recognise the significance of all variations from normal conditions. The marked utility of the object thus sought by the author is self-evident, and his long experience and assiduous devotion to its thorough development are a sufficient guarantee of the manner in which his aims have been carried out. No pains have been spared with the illustrations. Those of normal anatomy are from original dissections, drawn on stone by Mr. Hermann Faber, with the name of every part clearly engraved upon the figure, after the manner of "Holden" and "Gray," and in every typographical detail it will be the effort of the publishers to render the volume worthy of the very distinguished position which is anticipated for it.

ELLIS (GEORGE VINER)
Emeritus Professor of Anatomy in University College, London.

DEMONSTRATIONS OF ANATOMY; Being a Guide to the Knowledge of the Human Body by Dissection. By GEORGE VINER ELLIS, Emeritus Professor of Anatomy in University College, London. From the Eighth and Revised London Edition. In one very handsome octavo volume of over 700 pages, with 256 illustrations. Cloth, $4.25; leather, $5.25. (*Lately Issued.*)

This work has long been known in England as the leading authority on practical anatomy, and the favorite guide in the dissecting-room, as is attested by the numerous editions through which it has passed. In the last revision, which has just appeared in London, the accomplished author has sought to bring it on a level with the most recent advances of science by making the necessary changes in his account of the microscopic structure of the different organs, as developed by the latest researches in textural anatomy.

Ellis's Demonstrations is the favorite text-book of the English student of anatomy. In passing through eight editions it has been so revised and adapted to the needs of the student that it would seem that it had almost reached perfection in this special line. The descriptions are clear, and the methods of pursuing anatomical investigations are given with such detail that the book is honestly entitled to its name.—*St. Louis Clinical Record*, June, 1879.

The success of this old manual seems to be as well deserved in the present as in the past volumes. The book seems destined to maintain yet for years its leadership over the English manuals upon dissecting.—*Phila. Med. Times*, May 24, 1879.

As a dissector, or a work to have in hand and studied while one is engaged in dissecting, we regard it as the very best work extant, which is certainly saying a very great deal. As a text-book to be studied in the dissecting-room, it is superior to any of the works upon anatomy.—*Cincinnati Med. News*, May 24, 1879.

We most unreservedly recommend it to every practitioner of medicine who can possibly get it.—*Va. Med. Monthly*, June, 1879.

WILSON (ERASMUS), F.R.S.

A SYSTEM OF HUMAN ANATOMY, General and Special. Edited by W. H. GOBRECHT, M.D., Professor of General and Surgical Anatomy in the Medical College of Ohio. Illustrated with three hundred and ninety-seven engravings on wood. In one large and handsome octavo volume, of over 600 pages; cloth, $4; leather, $5.

SMITH (HENRY H.), M.D., and HORNER (WILLIAM E.), M.D.,
Prof. of Surgery in the Univ. of Penna., &c. — *Late Prof. of Anatomy in the Univ. of Penna.*

AN ANATOMICAL ATLAS; Illustrative of the Structure of the Human Body. In one volume, large imperial octavo, cloth, with about six hundred and fifty beautiful figures. $4 50.

SCHÄFER (EDWARD ALBERT), M.D.,
Assistant Professor of Physiology in University College, London.

A COURSE OF PRACTICAL HISTOLOGY: Being an Introduction to the Use of the Microscope. In one handsome royal 12mo. volume of 304 pages, with numerous illustrations: cloth, $2 00. (*Lately Issued.*)

HORNER'S SPECIAL ANATOMY AND HISTOLOGY. Eighth edition, extensively revised and modified. In 2 vols. 8vo., of over 1000 pages, with 320 wood-cuts: cloth, $6 00

SHARPEY AND QUAIN'S HUMAN ANATOMY. Revised, by JOSEPH LEIDY, M.D., Prof of Anat. in Univ. of Penn. In two octavo vols. of about 1300 pages, with 511 illustrations Cloth, $6 00.

BELLAMY'S STUDENT'S GUIDE TO SURGICAL ANATOMY: A Text-book for Students preparing for their Pass Examination. With engravings on wood In one handsome royal 12mo. volume. Cloth, $2 25.

CLELAND'S DIRECTORY FOR THE DISSECTION OF THE HUMAN BODY. In one small volume, royal 12mo. of 182 pages: cloth $1 25.

HARTSHORNE'S HANDBOOK OF ANATOMY AND PHYSIOLOGY. Second edition, revised. In one royal 12mo. vol., with 220 wood-cuts; cloth $1 75.

DALTON (J. C.), M.D.,

Professor of Physiology in the College of Physicians and Surgeons, New York, &c.

A TREATISE ON HUMAN PHYSIOLOGY. Designed for the use of Students and Practitioners of Medicine. Seventh edition, thoroughly revised and rewritten, with about three hundred and sixty illustrations on wood. In one very beautiful octavo volume, of about 900 pages. (*Nearly Ready.*)

A few notices of the previous edition are appended.

Prof. Dalton has discussed conflicting theories and conclusions regarding physiological questions with a fairness, a fulness, and a conciseness which lend freshness and vigor to the entire book. But his discussions have been so guarded by a refusal of admission to those speculative and theoretical explanations, which at best exist in the minds of observers themselves as only probabilities, that none of his readers need be led into grave errors while making them a study.—*The Medical Record*, Feb. 19, 1876.

For clearness and perspicuity, Dalton's Physiology commended itself to the student years ago, and was a pleasant relief from the verbose productions which it supplanted. Physiology has, however, made many advances since then—and while the style has been preserved intact, the work in the present edition has been brought up fully abreast of the times. The new chemical notation and nomenclature have also been introduced into the present edition. Notwithstanding the multiplicity of text-books on physiology, this will lose none of its old time popularity. The mechanical execution of the work is all that could be desired.—*Peninsular Journal of Medicine*, Dec. 1875.

This popular text-book on physiology comes to us in its sixth edition with the addition of about fifty per cent. of new matter, chiefly in the departments of pathological chemistry and the nervous system, where the principal advances have been realised. With so thorough revision and additions, that keep the work well up to the times, its continued popularity may be confidently predicted, notwithstanding the competition it may encounter. The publisher's work is admirably done.—*St. Louis Med. and Surg. Journ.*, Dec. 1875.

The revision of this great work has brought it forward with the physiological advances of the day, and renders it, as it has ever been, the finest work for students extant.—*Nashville Journ. of Med. and Surg.*, Jan. 1876.

CARPENTER (WILLIAM B.), M. D., F. R. S., F.G.S., F.L.S.,

Registrar to University of London, etc.

PRINCIPLES OF HUMAN PHYSIOLOGY; Edited by HENRY POWER, M.B. Lond., F.R.C.S., Examiner in Natural Sciences, University of Oxford. A new American from the Eighth Revised and Enlarged English Edition, with Notes and Additions, by FRANCIS G. SMITH, M.D., Professor of the Institutes of Medicine in the University of Pennsylvania, etc. In one very large and handsome octavo volume, of 1083 pages, with two plates and 373 engs. on wood. Cloth, $5 50; leather, $6 50; half Russia, $7.

We have been agreeably surprised to find the volume so complete in regard to the structure and functions of the nervous system in all its relations, a subject that, in many respects, is one of the most difficult of all, in the whole range of physiology, upon which to produce a full and satisfactory treatise of the class to which the one before us belongs. The additions by the American editor give to the work as it is a considerable value beyond that of the last English edition. In conclusion, we can give our cordial recommendation to the work as it now appears. The editors have, with their additions to the only work on physiology in our language that, in the fullest sense of the word, is the production of a philosopher as well as a physiologist, brought it up as fully as could be expected, if not desired, to the standard of our knowledge of its subject at the present day. It will deservedly maintain the place it has always had in the favor of the medical profession.—*Journ. of Nervous and Mental Disease*, April, 1877.

Such enormous advances have recently been made in our physiological knowledge, that what was perfectly new a year or two ago, looks now as if it had been a received and established fact for years. In this encyclopædic way it is unrivalled. Here, as it seems to us, is the great value of the book; one is safe in sending a student to it for information on almost any given subject, perfectly certain of the fulness of information it will convey, and well satisfied of the accuracy with which it will there be found stated.—*London Med. Times and Gazette*, Feb. 17, 1877.

The merits of "Carpenter's Physiology" are so widely known and appreciated that we need only allude briefly to the fact that in the latest edition will be found a comprehensive embodiment of the results of recent physiological investigation. Care has been taken to preserve the practical character of the original work. In fact the entire work has been brought up to date, and bears evidence of the amount of labor that has been bestowed upon it by its distinguished editor, Mr. Henry Power. The American editor has made the latest additions, in order fully to cover the time that has elapsed since the last English edition.—*N. Y. Med. Journal*, Jan. 1877.

FOSTER (MICHAEL), M.D., F.R.S.,

Prof. of Physiology in Cambridge Univ., England.

TEXT-BOOK OF PHYSIOLOGY. Second American from the Latest English Edition. Edited, with Extensive Notes and Additions, by EDWARD T. REICHERT, M.D., Late Demonstrator of Experimental Therapeutics in the Univ. of Penna. In one handsome royal 12mo. volume of about 1000 pages, with 260 illustrations. Cloth, $3 25; leather, $3 75. (*Just Ready.*)

In the preparation of a second American edition of Mr. Foster's Physiology, the editor has endeavored to render it more than ever acceptable to the student as a clear and comprehensive text-book, presenting the science in its latest developments. The original work being an exposition of abstract physiology without any reference to the details of physiological anatomy, it seemed desirable to introduce some account of structure, in order to render more intelligible to the student the views and theories of the science. This the editor has added, in as concise a manner as possible; and in aid of this end has freely introduced illustrations from recognized authorities.

LEHMANN'S MANUAL OF CHEMICAL PHYSIOLOGY. Translated from the German, with Notes and Additions, by J. CHESTON MORRIS, M.D. With illustrations on wood. In one octavo volume of 336 pages. Cloth, $2 25.

LEHMANN'S PHYSIOLOGICAL CHEMISTRY. Complete in two large octavo volumes of 1200 pages, with 200 illustrations; cloth, $6.

ATTFIELD (JOHN), Ph.D.,

Professor of Practical Chemistry to the Pharmaceutical Society of Great Britain, &c.

CHEMISTRY, GENERAL, MEDICAL AND PHARMACEUTICAL;

Including the Chemistry of the U. S. Pharmacopœia. A Manual of the General Principles of the Science, and their Application to Medicine and Pharmacy. Eighth edition, revised by the author. In one handsome royal 12mo. volume of 700 pages, with illustrations. Cloth, $2 50; leather, $3 00. (*Now Ready.*)

We have repeatedly expressed our favorable opinion of this work, and on the appearance of a new edition of it, little remains for us to say, except that we expect this eighth edition to be as indispensable to us as the seventh and previous editions have been. While the general plan and arrangement have been adhered to, new matter has been added covering the observations made since the former edition. The present differs from the preceding one chiefly in these alterations and in about ten pages of useful tables added in the appendix.—*Am. Journ. of Pharmacy*, May, 1879.

A standard work like Attfield's Chemistry need only be mentioned by its name, without further comments. The present edition contains such alterations and additions as seemed necessary for the demonstration of the latest developments of chemical principles, and the latest applications of chemistry to pharmacy. The author has bestowed arduous labor on the revision, and the extent of the information thus introduced may be estimated from the fact that the index contains three hundred new references relating to additional material.—*Druggists' Circular and Chemical Gazette*, May, 1879.

This very popular and meritorious work has now reached its eighth edition, which fact speaks in the highest terms in commendation of its excellence. It has now become the principal text-book of chemistry in all the medical colleges in the United States. The present edition contains such alterations and additions as seemed necessary for the demonstration of the latest developments of chemical principles, and the latest applications of chemistry to pharmacy. It is scarcely necessary for us to say that it exhibits chemistry in its present advanced state.—*Cincinnati Medical News*, April, 1879.

The popularity which this work has enjoyed is owing to the original and clear disposition of the facts of the science, the accuracy of the details, and the omission of much which freights many treatises heavily without bringing corresponding instruction to the reader. Dr. Attfield writes for students, and primarily for medical students; he always has an eye to the pharmacopœia and its officinal preparations; and he is continually putting the matter in the text so that it responds to the questions with which each section is provided. Thus the student learns easily, and can always refresh and test his knowledge.—*Med. and Surg. Reporter*, April 19, '79.

We noticed only about two years and a half ago the publication of the preceding edition, and remarked upon the exceptionally valuable character of the work. The work now includes the whole of the chemistry of the pharmacopœia of the United States, Great Britain, and India.—*New Remedies*, May, 1879.

GREENE (WILLIAM H.), M.D.,

Demonstrator of Chemistry in Med. Dept., Univ. of Penna.

A MANUAL OF MEDICAL CHEMISTRY. For the Use of Students.

Based upon Bowman's Medical Chemistry. In one royal 12mo. volume of 312 pages With illustrations. Cloth, $1 75. (*Now Ready.*)

It is well written, and gives the latest views on vital chemistry, a subject with which most physicians are not sufficiently familiar. To those who may wish to improve their knowledge in that direction, we can heartily recommend this work as being worthy of a careful perusal.—*Phila. Med. and Surg. Reporter*, April 24, 1880.

The little work before us is one which we think will be studied with pleasure and profit. The descriptions, though brief, are clear, and in most cases sufficient for the purpose. This book will, in nearly all cases, meet general approval.—*Am. Journ. of Pharmacy*, April, 1880.

CLASSEN (ALEXANDER),

Professor in the Royal Polytechnic School, Aix-la-Chapelle.

ELEMENTARY QUANTITATIVE ANALYSIS. Translated with

notes and additions by EDGAR F. SMITH, Ph.D., Assistant Prof. of Chemistry in the Towne Scientific School, Univ. of Penna. In one handsome royal 12mo. volume, of 324 pages, with illustrations; cloth, $2 00. (*Lately Issued.*)

It is probably the best manual of an elementary nature extant, inasmuch as its methods are the best. It teaches by examples, commencing with single determinations, followed by separations, and then advancing to the analysis of minerals and such products as are met with in applied chemistry. It is an indispensable book for students in chemistry.—*Boston Journ. of Chemistry*, Oct. 1878.

GALLOWAY (ROBERT), F.C.S.,

Prof. of Applied Chemistry in the Royal College of Science for Ireland, etc.

A MANUAL OF QUALITATIVE ANALYSIS. From the Fifth London Edition.

In one neat royal 12mo. volume, with illustrations; cloth, $2 75.

REMSEN (IRA), M.D., Ph.D.,

Professor of Chemistry in the Johns Hopkins University, Baltimore.

PRINCIPLES OF THEORETICAL CHEMISTRY, with special reference

to the Constitution of Chemical Compounds. In one handsome royal 12mo. vol. of over 232 pages: cloth, $1 50.

BOWMAN'S INTRODUCTION TO PRACTICAL CHEMISTRY, INCLUDING ANALYSIS. Sixth American, from the Sixth and revised London edition. With numerous illustrations. In one neat vol., royal 12mo., cloth, **$2 25.**

WÖHLER AND FITTIG'S OUTLINES OF ORGANIC CHEMISTRY. Translated, with additions, from the Eighth German Edition. By IRA REMSEN, M.D., Ph.D., Prof. of Chemistry and Physics in Williams College, Mass. In one volume, royal 12mo. of 550 pp., cloth, **$3.**

FOWNES (GEORGE), Ph.D.

A MANUAL OF ELEMENTARY CHEMISTRY; Theoretical and Practical.

Revised and corrected by HENRY WATTS, B.A., F.R.S., author of "A Dictionary of Chemistry," etc. With a colored plate, and one hundred and seventy-seven illustrations. A new American, from the Twelfth and enlarged London edition. Edited by ROBERT BRIDGES, M.D. In one large royal 12mo. volume, of over 1000 pages; cloth, $2 75; leather, $3 25. (*Lately Issued.*)

This work, inorganic and organic, is complete in one convenient volume. In its earliest editions it was fully up to the latest advancements and theories of that time. In its present form, it presents, in a remarkably convenient and satisfactory manner, the principles and leading facts of the chemistry of *to-day*. Concerning the manner in which the various subjects are treated, much deserves to be said, and mostly, too, in praise of the book. A review of such a work as *Fownes's Chemistry* within the limits of a book-notice for a medical weekly is simply out of the question.—*Cincinnati Lancet and Clinic*, Dec. 14, 1878.

When we state that, in our opinion, the present edition sustains in every respect the high reputation which its predecessors have acquired and enjoyed, we express therewith our full belief in its intrinsic value as a text-book and work of reference.—*Am. Journ. of Pharm.*, Aug. 1878.

The conscientious care which has been bestowed upon it by the American and English editors renders it still, perhaps, the best book for the student and the practitioner who would keep alive the acquisitions of his student days. It has, indeed, reached a somewhat formidable magnitude with its more than a thousand pages, but with less than this no fair representation of chemistry as it now is can be given. The type is small but very clear, and the sections are very lucidly arranged to facilitate study and reference.—*Med and Surg. Reporter*, Aug 3, 1878.

The work is too well known to American students to need any extended notice; suffice it to say that the revision by the English editor has been faithfully done, and that Professor Bridges has added some fresh and valuable matter, especially in the inorganic chemistry. The book has always been a favorite in this country, and in its new shape bids fair to retain all its former *prestige*.—*Boston Jour. of Chemistry*, Aug. 1878.

It will be entirely unnecessary for us to make any remarks relating to the general character of Fownes' Manual For over twenty years it has held *the* foremost place as a text-book, and the elaborate and thorough revisions which have been made from time to time leave little chance for any wide awake rival to step before it.—*Canadian Pharm. Jour.*, Aug. 1878.

As a manual of chemistry it is without a superior in the language.—*Md. Med. Jour.*, Aug. 1878.

BLOXAM (C. L.),

Professor of Chemistry in King's College, London.

CHEMISTRY, INORGANIC AND ORGANIC.

From the Second London Edition. In one very handsome octavo volume, of 700 pages, with about 300 illustrations. Cloth, $4 00; leather, $5 00.

We have in this work a complete and most excellent text-book for the use of schools, and can heartily recommend it as such.—*Boston Med. and Surg. Journ.*, May 28, 1874.

The above is the title of a work which we can most conscientiously recommend to students of chemistry. It is as easy as a work on chemistry could be made, at the same time that it presents a full account of that science as it now stands. We have spoken of the work as admirably adapted to the wants of students; it is quite as well suited to the requirements of practitioners who wish to review their chemistry, or have occasion to refresh their memories on any point relating to it. In a word, it is a book to be read by all who wish to know what is the chemistry of the present day.—*American Practitioner*, Nov. 1873.

It would be difficult for a practical chemist and teacher to find any material fault with this most admirable treatise. The author has given us almost a cyclopædia within the limits of a convenient volume, and has done so without penning the *useless* paragraphs too commonly making up a great part of the bulk of many cumbrous works. The progressive scientist is not disappointed when he looks for the record of new and valuable processes and discoveries, while the cautious conservative does not find its pages monopolized by uncertain theories and speculations. A peculiar point of excellence is the crystallized form of expression in which great truths are expressed in very short paragraphs. One is surprised at the brief space allotted to an important topic, and yet, after reading it, he feels that little, if any more should have been said. Altogether, it is seldom yet see a text-book so nearly faultless. — *Cincinnati Lancet*, Nov. 1873.

CLOWES (FRANK), D.Sc., London.

Senior Science-Master at the High School, Newcastle-under-Lyme, etc.

AN ELEMENTARY TREATISE ON PRACTICAL CHEMISTRY AND QUALITATIVE INORGANIC ANALYSIS.

Specially adapted for Use in the Laboratories of Schools and Colleges and by Beginners. Second American from the Third and Revised English Edition. In one very handsome royal 12mo. volume of 372 pages, with 47 illustrations. Cloth, $2 50. (*Just Ready.*)

This is a valuable work for those about to commence chemistry, the more so as by its use they are simultaneously acquainted with the manipulation of chemical analysis, a method which is the most valuable to impart a thorough knowledge of chemistry. It is a very good little book, and will make for itself many warm friends and supporters. It treats the subject well and the tables are very clear and valuable.—*St. Louis Med. and Surg. Journ.*, Mar. 1881.

This work is not only well adapted for use as a text-book in medical colleges, but is also one of the best that a practitioner can have for convenient reference and instruction in his library. As a rule, such volumes are too technical and abstruse for study without some didactic aid, but the volume presented is easy of comprehension, and will be of great value to college students and busy practitioners.—*N. Y. Am. Med. Bi-Weekly*, April 9, 1881.

The tables particularly demand praise, for they are admirably formed, both for convenience of reference and fulness of information. In short, we do not remember to have met with a book which could better serve the student as a guide to the systematic study of inorganic chemistry.—*Louisville Med. News*, March 12, 1881.

KNAPP'S TECHNOLOGY; or Chemistry Applied to the Arts and to Manufactures. With American additions by Prof. WALTER R. JOHNSON. In two very handsome octavo volumes, with 500 wood engravings, cloth, $6 00.

HOFFMAN (FRED.), Ph.D. and, POWER (FRED. B.), Ph.D.,

Prof. of Anal. Chem. in Phil Coll. of Pharmacy.

MANUAL OF CHEMICAL ANALYSIS, as Applied to the Examination of Medical Chemicals and their Preparations.

Being a Guide for the Determination of their Identity and Quality, and for the Detection of Impurities and Adulterations. For the Use of Pharmacists, Physicians, Druggists and Manufacturing Chemists, and Pharmaceutical and Medical Students. Third edition, entirely rewritten and much enlarged. In one very handsome octavo volume, fully illustrated. (*Preparing.*)

PARRISH (EDWARD),

Late Professor of Materia Medica in the Philadelphia College of Pharmacy.

A TREATISE ON PHARMACY.

Designed as a Text-Book for the Student, and as a Guide for the Physician and Pharmaceutist. With many Formulæ and Prescriptions. Fourth Edition, thoroughly revised, by THOMAS S. WIEGAND. In one handsome octavo volume of 977 pages, with 280 illustrations; cloth, $5 50; leather, $6 50; half Russia, $7

Of Dr. Parrish's great work on pharmacy it only remains to be said that the editor has accomplished his work so well as to maintain, in this fourth edition, the high standard of excellence which it had attained in previous editions, under the editorship of its accomplished author. This has not been accomplished without much labor, and many additions and improvements, involving changes in the arrangement of the several parts of the work, and the addition of much new matter. With the modifications thus effected it constitutes, as now presented, a compendium of the science and art indispensable to the pharmacist, and of the utmost value to every practitioner of medicine desirous of familiarizing himself with the pharmaceutical preparation of the articles which he prescribes for his patients.—*Chicago Med. Journ.*, July, 1874.

The work is eminently practical, and has the rare merit of being readable and interesting, while it preserves a strictly scientific character The whole work reflects the greatest credit on author, editor and publisher. It will convey some idea of the liberality which has been bestowed upon its production when we mention that there are no less than 280 carefully executed illustrations. In conclusion, we heartily recommend the work, not only to pharmacists, but also to the multitude of medical practitioners who are obliged to compound their own medicines. It will ever hold an honored place on our own bookshelves.—*Dublin Med. Press and Circular*, Aug. 12, 1874.

Perhaps one, if not the most important book upon pharmacy which has appeared in the English language has emanated from the transatlantic press. "Parrish's Pharmacy" is a well-known work on this side of the water, and the fact shows us that a really useful work never becomes merely local in its fame. Thanks to the judicious editing of Mr. Wiegand, the posthumous edition of "Parrish" has been saved to the public with all the mature experience of its author, and perhaps none the worse for a dash of new blood.—*Lond. Pharm. Journal*, Oct. 17, 1874.

GRIFFITH (ROBERT E.), M.D.

A UNIVERSAL FORMULARY, Containing the Methods of Preparing and Administering Officinal and other Medicines.

The whole adapted to Physicians and Pharmaceutists. Third edition, thoroughly revised, with numerous additions, by JOHN M. MAISCH, Professor of Materia Medica in the Philadelphia College of Pharmacy. In one large and handsome octavo volume of about 800 pages. Cloth, $4 50; leather, $5 50.

A more complete formulary than it is in its present form the pharmacist or physician could hardly desire. To the first some such work is indispensable, and it is hardly less essential to the practitioner who compounds his own medicines. Much of what is contained in the introduction ought to be committed to memory by every student of medicine As a help to physicians it will be found invaluable, and doubtless will make its way into libraries no already supplied with a standard work of the kind. —*The American Practitioner*, Louisville, July, '74.

FARQUHARSON (ROBERT), M.D.,

Lecturer on Materia Medica at St. Mary's Hospital Medical School.

A GUIDE TO THERAPEUTICS AND MATERIA MEDICA.

Second American edition, revised by the Author. Enlarged and adapted to the U. S. Pharmacopœia. By FRANK WOODBURY, M.D. In one neat royal 12mo. volume of 498 pages: cloth, $2.25. (*Lately Issued.*)

The appearance of a new edition of this convenient and handy book in less than two years may certainly be taken as an indication of its usefulness. Its convenient arrangement, and its terseness, and, at the same time, completeness of the information given, make it a handy book of reference.—*Am. Journ of Pharmacy*, June, 1879.

This work contains in moderate compass such well-digested facts concerning the physiological and therapeutical action of remedies as are reasonably established up to the present time. By a convenient arrangement the corresponding effects of each article in health and disease are presented in parallel columns, not only rendering reference easier, but also impressing the facts more strongly upon the mind of the reader. The book has been adapted to the wants of the American student, and copious notes have been introduced, embodying the latest revision of the Pharmacopœia, together with the antidotes to the more prominent poisons, and such of the newer remedial agents as seemed necessary to the completeness of the work. Tables of weights and measures, and a good alphabetical index end the volume.—*Druggists' Circular and Chemical Gazette*, June, 1879.

It is a pleasure to think that the rapidity with which a second edition is demanded may be taken as an indication that the sense of appreciation of the value of reliable information regarding the use of remedies is not entirely overwhelmed in the cultivation of pathological studies, characteristic of the present day. This work certainly merits the success it has so quickly achieved.—*New Remedies*, July, '79.

CHRISTISON'S DISPENSATORY. With copious additions, and 213 large wood engravings By R. EGLESFIELD GRIFFITH, M.D. One vol. 8vo., pp. 1000 cloth, $4 00.

CARPENTER'S PRIZE ESSAY ON THE USE OF ALCOHOLIC LIQUORS IN HEALTH AND DISEASE. New edition, with a Preface by D. F CONDIE M D., and explanations of scientific words. In one neat 12mo. volume, pp. 178, cloth, 60 cents.

STILLÉ (ALFRED), M.D., LL.D., and MAISCH (JOHN M.), Ph.D.
Prof. of Theory and Practice of Medicine and of Clinical Med. in Univ. of Pa.
Prof. of Mat. Med. and Bot. in Phila. Coll. Pharmacy, Secy. to the American Pharmaceutical Association.

THE NATIONAL DISPENSATORY: Containing the Natural History, Chemistry, Pharmacy, Actions and Uses of Medicines, including those recognized in the Pharmacopœias of the United States, Great Britain and Germany, with numerous references to the French Codex. Second edition, thoroughly revised, with numerous additions. In one very handsome octavo volume of 1692 pages, with 239 illustrations. Extra cloth, $6 75; leather, raised bands, $7 50; half Russia, raised bands and open back, $8 25. (*Now Ready.*)

PREFACE TO THE SECOND EDITION.

The demand which has exhausted in a few months an unusually large edition of the National Dispensatory is doubly gratifying to the authors, as showing that they were correct in thinking that the want of such a work was felt by the medical and pharmaceutical professions, and that their efforts to supply that want have been acceptable. This appreciation of their labors has stimulated them in the revision to render the volume more worthy of the very marked favor with which it has been received. The first edition of a work of such magnitude must necessarily be more or less imperfect; and though but little that is new and important has been brought to light in the short interval since its publication, yet the length of time during which it was passing through the press rendered the earlier portions more in arrears than the later. The opportunity for a revision has enabled the authors to scrutinize the work as a whole, and to introduce alterations and additions wherever there has seemed to be occasion for improvement or greater completeness. The principal changes to be noted are the introduction of several drugs under separate headings, and of a large number of drugs, chemicals and pharmaceutical preparations classified as allied drugs and preparations under the heading of more important or better known articles: these additions comprise in part nearly the entire German Pharmacopœia and numerous articles from the French Codex. All new investigations which came to the authors' notice up to the time of publication have received due consideration.

The series of illustrations has undergone a corresponding thorough revision. A number have been added, and still more have been substituted for such as were deemed less satisfactory.

The new matter embraced in the text is equal to nearly one hundred pages of the first edition. Considerable as are these changes as a whole, they have been accommodated by an enlargement of the page without increasing unduly the size of the volume.

While numerous additions have been made to the sections which relate to the physiological action of medicines and their use in the treatment of disease, great care has been taken to make them as concise as was possible without rendering them incomplete or obscure. The doses have been expressed in the terms both of troy weight and of the metrical system, for the purpose of making those who employ the Dispensatory familiar with the latter, and paving the way for its introduction into general use.

The Therapeutical Index has been extended by about 2250 new references, making the total number in the present edition about 6000.

The articles there enumerated as remedies for particular diseases are not only those which, in the authors' opinion, are curative, or even beneficial, but those also which have at any time been employed on the ground of popular belief or professional authority. It is often of as much consequence to be acquainted with the worthlessness of certain medicines or with the narrow limits of their power, as to know the well attested virtues of others and the conditions under which they are displayed. An additional value possessed by such an Index is, that it contains the elements of a natural classification of medicines, founded upon an analysis of the results of experience, which is the only safe guide in the treatment of disease.

This evidence of success, seldom paralleled, shows clearly how well the authors have met the existing needs of the pharmaceutical and medical professions. Gratifying as it must be to them, they have embraced the opportunity offered for a thorough revision of the whole work, striving to embrace within it all that might have been omitted in the former edition, and all that has newly appeared of sufficient importance during the time of its collaboration, and the short interval elapsed since the previous publication. After having gone carefully through the volume we must admit that the authors have labored faithfully, and with success, in maintaining the high character of their work as a compendium meeting the requirements of the day, to which one can safely turn in quest of the latest information concerning everything worthy of notice in connection with Pharmacy, Materia Medica, and Therapeutics.—*Am. Jour. of Pharmacy*, Nov. 1879.

It is with great pleasure that we announce to our readers the appearance of a *second* edition of the National Dispensatory. The total exhaustion of the first edition in the short space of six months, is a sufficient testimony to the value placed upon the work by the profession. It appears that the rapid sale of the first edition must have induced both the editors and the publisher to make preparations for a new edition immediately after the first had been issued, for we find a large amount of new matter added and a good deal of the previous text altered and improved, which proves that the authors do not intend to let the grass grow under their feet, but to keep the work up to the time.—*New Remedies*, Nov. 1879.

This is a great work by two of the ablest writers on materia medica in America. The authors have produced a work which, for accuracy and comprehensiveness, is unsurpassed by any work on the subject. There is no book in the English language which contains so much valuable information on the various articles of the materia medica. The work has cost the authors years of laborious study, but they have succeeded in producing a dispensatory which is not only *national*, but will be a lasting memorial of the learning and ability of the authors who produced it.—*Edinburgh Medical Journal*, Nov. 1879.

It is by far more international or universal than any other book of the kind in our language, and more comprehensive in every sense.—*Pacific Med. and Surg. Journ.*, Oct. 1879.

The National Dispensatory is beyond dispute the very best authority. It is throughout complete in all the necessary details, clear and lucid in its explanations, and replete with references to the most recent writings, where further particulars can be obtained, if desired. Its value is greatly enhanced by the extensive indices—a general index of materia medica, etc., and also an index of therapeutics. It would be a work of supererogation to say more about this well-known work. No practising physician can afford to be without the National Dispensatory.—*Canada Med. and Surg. Journ.*, Feb. 1880.

MAISCH (JOHN M.), Phar. D.,

Prof. of Materia Medica and Botany in the Phila. Coll. of Pharmacy.

A MANUAL OF ORGANIC MATERIA MEDICA. Being a Guide to Materia Medica of the Vegetable and Animal Kingdoms. For the use of Students, Druggists, Pharmacists and Physicians. In one handsome 12mo. volume, with numerous illustrations on wood. (*Preparing.*)

EXTRACT FROM THE AUTHOR'S PREFACE.

When in 1866 the author was called to the chair of Materia Medica in the institution named (the Philadelphia College of Pharmacy), he seriously felt the need of a suitable text book which could be used in connection with his lectures, and made preparations for the publication of such a work at an early date. To elaborate a system of classification, which should be without difficulty comprehended and readily applied by those for whom it was intended, was by no means an easy task, and the author found occasion, almost every year, to either remodel that previously selected, or to make what in his opinion seemed to be desirable improvements. The publication of the "National Dispensatory" in a measure supplied the want felt, at least as far as a work of reference is concerned, but owing to its local arrangement, it is not adapted to systematic instruction. However, its publication rendered a modification of the original plan for a treatise on Materia Medica desirable, and it is now presented in a form giving an outline of the substance of the lectures and embracing what are considered the essential physical, histological, and chemical characters of the organic drug, so as to render the work also a useful and reliable guide in business transactions. Regarding the classification, the author is conscious of its imperfections, but he believes it to be convenient and capable of practical application.

In reference to the scope of the work, the main aim has been to embrace all the drugs recognized by the U. S. Pharmacopœia, together with the old, but now unofficinal ones, and such others, the use of which has been recently revived or suggested, and which seem to deserve attention. The medical properties and doses of the various drugs are merely briefly stated as subjects of general important information; the present work is not intended for giving instruction in the therapeutic application of drugs.

STILLÉ (ALFRED), M. D.,

Professor of Theory and Practice of Medicine in the University of Penna.

THERAPEUTICS AND MATERIA MEDICA; a Systematic Treatise on the Action and Uses of Medicinal Agents, including their Description and History. Fourth edition, revised and enlarged. In two large and handsome 8vo. vols. of about 2000 pages. Cloth, $10; leather, $12; half Russia, $13.

It is unnecessary to do much more than to announce the appearance of the fourth edition of this well known and excellent work.—*Brit. and For. Med.-Chir. Review*, Oct 1875.

For all who desire a complete work on therapeutics and materia medica for reference, in cases involving medico-legal questions, as well as for information concerning remedial agents, Dr. Stillé's is "*par excellence*" the work. Being out of print, by the exhaustion of former editions, the author has laid the profession under renewed obligations, by the careful revision, important additions, and timely reissuing a work not exactly supplemented by any other in the English language, if in any language. The mechanical execution handsomely sustains the well-known skill and good taste of the publisher.—*St. Louis Med. and Surg. Journal*, Dec 1874.

From the publication of the first edition "Stillé's Therapeutics" has been one of the classics; its absence from our libraries would create a vacuum which could be filled by no other work in the language, and its presence supplies, in the two volumes of the present edition, a whole cyclopædia of therapeutics.—*Chicago Medical Journal*, Feb. 1875.

The rapid exhaustion of three editions and the universal favor with which the work has been received by the medical profession, are sufficient proof of its excellence as a repertory of practical and useful information for the physician. The edition before us fully sustains this verdict, as the work has been carefully revised and in some portions rewritten, bringing it up to the present time by the admission of chloral and croton-chloral, nitrite of amyl, bichloride of methylene, methylic ether, lithium compounds, gelseminum, and other remedies.—*Am. Journ. of Pharmacy*, Feb. 1875.

We can hardly admit that it has a rival in the multitude of its citations and the fulness of its research into clinical histories, and we must assign it a place in the physician's library; not, indeed, as fully representing the present state of knowledge in pharmacodynamics, but as by far the most complete treatise upon the clinical and practical side of the question.—*Boston Med. and Surg. Journal*, Nov. 5, 1874.

CORNIL (V.), AND RANVIER (L.),

Prof. in the Faculty of Med., Paris. *Prof in the College of France.*

MANUAL OF PATHOLOGICAL HISTOLOGY. Translated, with Notes and Additions, by E. O. SHAKESPEARE, M.D., Pathologist and Ophthalmic Surgeon to Philada. Hospital, Lecturer on Refraction and Operative Ophthalmic Surgery in Univ. of Penna., and by HENRY C. SIMMS, M D., Demonstrator of Pathological Histology in the Univ. of Pa. In one very handsome octavo volume of over 700 pages, with over 350 illustrations. Cloth, $5 50; leather, $6 50; half Russia, $7. (*Just Ready.*)

We have no hesitation in cordially recommending the English translation of Cornil & Ranvier's "Pathological Histology" as the best work of the kind in any language, and as giving to its readers a trustworthy guide in obtaining a broad and solid basis for the appreciation of the practical bearings of pathological anatomy.—*Am. Journ. of Med. Sciences*, April, 1880.

This important work, in its American dress, is a welcome offering to all students of the subjects which it treats. The great mass of material is arranged naturally and comprehensively. The classification of tumors is clear and full, so far as the subject admits of definition, and this one chapter is worth the price of the book. The illustrations are copious and well chosen. Without the slightest hesitation, the translators deserve honest thanks for placing this indispensable work in the hands of American students.—*Phila. Med. Times*, April 24, 1880

This volume we cordially commend to the profession. It will prove a valuable, almost necessary, addition to the libraries of students who are to be physicians, and to the libraries of students who are physicians.—*American Practitioner*, June, 1880.

FENWICK (SAMUEL), M.D.,

Assistant Physician to the London Hospital.

THE STUDENT'S GUIDE TO MEDICAL DIAGNOSIS.

From the Third Revised and Enlarged English Edition. With eighty-four illustrations on wood. In one very handsome volume, royal 12mo., cloth, $2 25. (*Lately Issued.*)

GREEN (T. HENRY), M.D.,

Lecturer on Pathology and Morbid Anatomy at Charing-Cross Hospital Medical School, etc.

PATHOLOGY AND MORBID ANATOMY.

Fourth American, from the Fifth Enlarged and Revised English Edition. In one very handsome octavo volume of about 350 pages, with 138 fine engravings; cloth, $2 25. (*Just Ready.*)

EXTRACT FROM THE AUTHOR'S PREFACE.

In preparing the fifth edition of my Text-book on Pathology and Morbid Anatomy, I have again added much new matter, with the object of making the work a more complete guide for the student. All the chapters have been carefully revised, some alterations have been made in the arrangement of the work, and an addition has been made to the number of wood-cuts. The new wood-cuts, as in previous editions, have been drawn by Mr. Collings from my own microscopical preparations.

We have long considered this the best guide yet presented to the student for the identification of various morbid tissues. We have found it more satisfactory than any other. The present edition has been thoroughly revised, and much new matter has been added. To the physician as a guide in diagnosis, we recommend this volume.—*Physician and Surgeon*, May, 1881.

BRISTOWE (JOHN SYER), M.D., F.R.C.P.,

Physician and Joint Lecturer on Medicine, St. Thomas's Hospital.

A TREATISE ON THE PRACTICE OF MEDICINE.

Second American edition, revised by the Author. Edited, with Additions, by JAMES H. HUTCHINSON, M.D., Physician to the Penna. Hospital. In one handsome octavo volume of nearly 1200 pages. With illustrations. Cloth, $5 00; leather, $6 00; half Russia, $6 50. (*Now Ready.*)

The second edition of this excellent work, like the first, has received the benefit of Dr. Hutchinson's annotations, by which the phases of disease which are peculiar to this country are indicated, and thus a treatise which was intended for British practitioners and students is made more practically useful on this side of the water. We see no reason to modify the high opinion previously expressed with regard to Dr. Bristowe's work, except by adding our appreciation of the careful labors of the author in following the lateral growth of medical science.—*Boston Medical and Surgical Journal*, February, 1880.

What we said of the first edition, we can, with increased emphasis, repeat concerning this: "Every page is characterized by the utterances of a thoughtful man. What has been said, has been well said, and the book is a fair reflex of all that is *certainly known* on the subjects considered."—*Ohio Med. Recorder*, Jan. 7, 1880.

The views of the author are expressed with precision and sufficient promptness to impress the student with the weight of his authority; and should the medical professor differ on any subject from his doctrine, he will need to find strong arguments to carry his class to the opposite conclusion.—*N. O. Med. and Surg. Journ.*, Feb. 1880.

The reader will find every conceivable subject connected with the practice of medicine ably presented, in a style at once clear, interesting, and concise. The additions made by Dr. Hutchinson are appropriate and practical, and greatly add to its usefulness to American readers.—*Buffalo Med. and Surg. Journ.*, March, 1880.

We regard it as an excellent work for students and for practitioners. It is clearly written, the author's style is attractive, and it is especially to be commended for its excellent exposition of the pathology and clinical phenomena of disease.—*St. Louis Clin. Record*, Feb. 1880.

HABERSHON (S. O.) M.D.

Senior Physician to, and late Lecturer on the Principles and Practice of Medicine at, Guy's Hospital, etc.

ON THE DISEASES OF THE ABDOMEN, COMPRISING THOSE

of the Stomach, and other parts of the Alimentary Canal, Œsophagus, Cæcum, Intestines and Peritoneum. Second American, from the Third enlarged and revised English edition. With illustrations. In one handsome octavo volume of over 500 pages. Cloth, $3 50. (*Lately Issued.*)

This valuable treatise on diseases of the stomach and abdomen has been out of print for several years, and is therefore not so well known to the profession as it deserves to be. It will be found a cyclopædia of information, systematically arranged, on all diseases of the alimentary tract, from the mouth to the rectum. A fair proportion of each chapter is devoted to symptoms, pathology, and therapeutics. The present edition is fuller than former ones in many particulars, and has been thoroughly revised and amended by the author. Several new chapters have been added, bringing the work fully up to the times, and making it a volume of interest to the practitioner in every field of medicine and surgery. Perverted nutrition is in some form associated with all diseases we have to combat, and we need all the light that can be obtained on a subject so broad and general. Dr. Habershon's work is one that every practitioner should read and study for himself.—*N. Y. Med. Journ.*, April, 1879.

GLUGE'S ATLAS OF PATHOLOGICAL HISTOLOGY. Translated, with Notes and Additions, by JOSEPH LEIDY, M. D. In one volume, very large imperial quarto, with 320 copper-plate figures, plain and colored, cloth. $4 00.

LA ROCHE ON YELLOW FEVER, considered in its Historical, Pathological, Etiological and Therapeutical Relations. In two large and handsome octavo volumes of nearly 1500 pp., cloth. $7 00.

STOKES' LECTURES ON FEVER. Edited by JOHN WILLIAM MOORE, M.D., Assistant Physician to the Cork Street Fever Hospital. In one neat 8vo volume cloth, $2 00.

PAVY'S TREATISE ON THE FUNCTION OF DIGESTION: its Disorders and their Treatment. From the Second London edition. In one handsome volume, small octavo, cloth, $2 00.

HOLLAND'S MEDICAL NOTES AND REFLECTIONS. 1 vol. 8vo., pp. 500, cloth. $3 50

BARLOW'S MANUAL OF THE PRACTICE OF MEDICINE. With Additions by D. F. CONDIE, M. D. 1 vol. 8vo., pp. 600. cloth. $2 50.

TODD'S CLINICAL LECTURES ON CERTAIN ACUTE DISEASES. In one neat octavo volume, of 320 pp. cloth. $2 50.

FLINT (AUSTIN), M.D.,

Professor of the Principles and Practice of Medicine in Bellevue Med. College, N. Y.

A TREATISE ON THE PRINCIPLES AND PRACTICE OF MEDICINE; designed for the use of Students and Practitioners of Medicine. Fifth edition, entirely rewritten and much improved. In one large and closely printed octavo volume of 1153 pp. Cloth, $5 50; leather, $6 50; very handsome half Russia, raised bands, $7. (*Just Ready.*)

This work has been so long and favorably known, and has obtained so high a position amongst modern treatises on medicine, that it is hardly necessary to do more than announce the publication of this fifth edition. All who peruse it must be struck by the extensive research which has been undertaken in the revision of this edition, combined with much original thought. There is hardly a subject which does not receive fresh illustration and discussion, opening up new lines of inquiry which had not been thought of when the previous edition appeared. We cannot conclude this notice without expressing our admiration of this volume, which is certainly one of the standard text-books on medicine, and we may safely affirm that, taken altogether, it exhibits a fuller and wider acquaintance with recent pathological inquiry than any similar work with which we are acquainted, whilst at the same time it shows its author to be possessed of the rare faculties of clear exposition, thoughtful discrimination, and sound judgment.—*London Lancet*, July 23, 1881.

Practically, this edition is a new work; for so many additions and changes have been made that one well acquainted with previous editions would hardly recognize this as an old friend. The size of the volume is somewhat increased. An entire new section and several new chapters have been added. It is universally conceded that no text book upon this subject was ever published in this country that can at all compare with it It has long been at the very head of American text-book literature, and there can be no doubt but that it will be many years before it yields the place to others.—*Nashville Journ. of Med. and Surg*, Feb. 1881.

"Flint's Practice" is recognized to be a standard treatise of high rank upon the principles and the practice of medicine wherever the English language is read. The opinions everywhere reveal the man of extensive experience, diligent study, calm judgment, and unbiassed criticism. The work should be in the hands of every practitioner.—*New York Med. Record*, Feb. 26, 1881.

The style and character of this work are too well known to the profession to require an introduction. For a number of years this volume has occupied a leading position as a text-book in the majority of medical schools, and the high position accorded to it in the past is a guarantee of a hearty welcome in this new edition The book may be said to represent the present state of the science of medicine as now understood and taught. It is a safe guide to students and practitioners of medicine.—*Maryland Medical Journal*, March 1, 1881.

The author has, in this edition, revised and rewritten a great part and made it accord with the more advanced ideas which have been developed within the past few years. He is the more fitted to do so, as he is actively engaged in his profession, and can make deductions, not from the work of others, but from his own labors. It is a treatise which every American physician should have upon his table, and which he should consult on occasions when his leisure permits him to do so.—*St. Louis Med and Surg. Journal*, March, 1881.

BY THE SAME AUTHOR.

CLINICAL MEDICINE; a Systematic Treatise on the Diagnosis and Treatment of Diseases. Designed for Students and Practitioners of Medicine. In one large and handsome octavo volume of 795 pages; cloth, $4 50; leather, $5 50; half Russia, $6. (*Now Ready.*)

The eminent teacher who has written the volume under consideration has recognized the needs of the American profession, and the result is all that we could wish. The style in which it is written is peculiarly the author's; it is clear and forcible, and marked by those characteristics which have rendered him one of the best writers and teachers this country has ever produced. We have not space for so full a consideration of this remarkable work as we would desire.—*St. Louis Clin. Record*, Oct. 1879.

It is here that the skill and learning of the great clinician are displayed He has given us a storehouse of medical knowledge, excellent for the student, convenient for the practitioner, the result of a long life of the most faithful clinical work, collected by an energy as vigilant and systematic as untiring, and weighed by a judgment no less clear than his observation is close.—*Archives of Medicine*, Dec. 1879

To give an adequate and useful conspectus of the extensive field of modern clinical medicine is a task of no ordinary difficulty; but to accomplish this consistently, with brevity and clearness, the different subjects and their several parts receiving the attention which, relatively to their importance, medical opinion claims for them, is still more difficult. This task we feel bound to say has been executed with more than partial success by Dr Flint, whose name is already familiar to students of advanced medicine in this country as that of the author of two works of great merit on special subjects, and of numerous papers, exhibiting much originality and extensive research —*The Dublin Journal*, Dec. 1879.

There is every reason to believe that this book will be well received. The active practitioner is frequently in need of some work that will enable him to obtain information in the diagnosis and treatment of cases with comparatively little labor. Dr. Flint has the faculty of expressing himself clearly, and at the same time so concisely as to enable the searcher to traverse the entire ground of his search, and at the same time obtain all that is essential, without plodding through an interminable space.—*N. Y. Med. Jour.*, Nov. 1879

The great object is to place before the reader the latest observations and experience in diagnosis and treatment. Such a work is especially valuable to students. It is complete in its special design, and yet so condensed, that he can by its aid, keep up with the lectures on practice without neglecting other branches. It will not escape the notice of the practitioner that such a work is most valuable in culling points in diagnosis and treatment in the intervals between the daily rounds of visits, since he can in a few minutes refresh his memory, or learn the latest advance in the treatment of diseases which demand his instant attention.—*Cincinnati Lancet and Clinic*, Oct. 25, 1879.

Fellow of the Royal College of Physicians, London.

PREVENTIVE MEDICINE. In one octavo volume of about 500 pages. (*Shortly.*)

HARTSHORNE (HENRY), M.D.,
Professor of Hygiene in the University of Pennsylvania.

ESSENTIALS OF THE PRINCIPLES AND PRACTICE OF MEDICINE. A handy book for Students and Practitioners Fifth edition, thoroughly revised and rewritten. With 140 illustrations. In one handsome royal 12mo. volume, of about 600 pages. (*In Press.*)

The very great success which has exhausted four large editions of this work shows that the author has succeeded in supplying a want felt by a large portion of the profession. It has also enabled him in successive revisions to perfect the details of his plan, and to render the work still more worthy of the favor with which it has been received. In the present edition several hundred brief additions have been made, a number of new subjects have been written upon, especially in connection with the Pathology of the Nervous System, the illustrations have been considerably increased, and a large number of new and carefully selected formulæ for the administration of medicines have been introduced. An account is given, also, in this edition for the first time, of the method of prescribing according to the metrical system, and a section is added upon Eyesight, its Examination and Correction. In presenting this edition, therefore, the publishers feel that it is in every way worthy a continuance of the favor hitherto accorded this work.

FOTHERGILL (J. MILNER), M.D. Edin., M.R.C.P. Lond.,
Asst. Phys. to the West Lond. Hosp.; Asst. Phys. to the City of Lond. Hosp., etc.

THE PRACTITIONER'S HANDBOOK OF TREATMENT; Or, the Principles of Therapeutics. Second edition, revised and enlarged. In one very neat octavo volume of about 650 pages. Cloth, $4 00; very handsome half Russia, $5 50. (*Just Ready.*)

The junior members of the profession will find in it a work that should not only be read, but carefully studied. It will assist them in the proper selection and combination of therapeutical agents best adapted to each case and condition, and enable them to prescribe intelligently and successfully. To do full justice to a work of this scope and character will be impossible in a review of this kind. The book itself must be read to be fully appreciated. —*St. Louis Courier of Medicine*, Nov. 1880.

The author merits the thanks of every well-educated physician for his efforts toward rationalizing the treatment of diseases upon the scientific basis of physiology. Every chapter, every line, has the impress of a master hand, and while the work is thoroughly scientific in every particular, it presents to the thoughtful reader all the charms and beauties of a well-written novel. No physician can well afford to be without this valuable work, for its originality makes it fill a niche in medical literature hitherto vacant.—*Nashville Journ. of Med. and Surg.*, Oct. 1880.

FINLAYSON (JAMES), M.D.,
Physician and Lecturer on Clinical Medicine in the Glasgow Western Infirmary, etc.

CLINICAL DIAGNOSIS; A Handbook for Students and Practitioners of Medicine. In one handsome 12mo. volume, of 546 pages, with 85 illustrations. Cloth, $2 63. (*Lately Issued.*)

The book is an excellent one, clear, concise, convenient, practical. It is replete with the very knowledge the student needs when he quits the lecture-room and the laboratory for the ward and sick-room, and does not lack in information that will meet the wants of experienced and older men.—*Phila. Med. Times*, Jan. 4, 1879.

This is one of the really useful books. It is attractive from preface to the final page, and ought to be given a place on every office table, because it contains in a condensed form all that is valuable in semeiology and diagnostics to be found in bulkier volumes, and because in its arrangement and complete index, it is unusually convenient for quick reference in any emergency that may come upon the busy practitioner. —*N. C. Med. Journ.*, Jan. 1879.

WATSON (THOMAS), M.D., &c.

LECTURES ON THE PRINCIPLES AND PRACTICE OF PHYSIC. Delivered at King's College, London. A new American, from the Fifth revised and enlarged English edition. Edited, with additions, and several hundred illustrations, by HENRY HARTSHORNE, M.D., Professor of Hygiene in the University of Pennsylvania. In two large and handsome 8vo. vols. Cloth, $9 00; leather, $11 00.

WILLIAMS'S PULMONARY CONSUMPTION; its Nature, Varieties and Treatment. With an Analysis of One Thousand Cases to exemplify its duration. In one neat octavo volume of about 350 pages; cloth, $2 50.

SLADE ON DIPHTHERIA; its Nature and Treatment, with an account of the History of its Prevalence in various Countries. Second and revised edition. In one neat royal 12mo. volume, cloth, $1 25.

WALSHE ON THE DISEASES OF THE HEART AND GREAT VESSELS. Third American Edition. In 1 vol. 8vo., 420 pp., cloth, $3 00.

SMITH ON CONSUMPTION; ITS EARLY AND REMEDIABLE STAGES. 1 vol. 8vo., pp. 254. $2 25.

FULLER ON DISEASES OF THE LUNGS AND AIR-PASSAGES. Their Pathology, Physical Diagnosis, Symptoms and Treatment. From the Second and revised English edition. In one handsome octavo volume of about 500 pages: cloth, $3 50.

REYNOLDS (J. RUSSELL), M.D.,

Prof. of the Principles and Practice of Medicine in Univ. College, London.

A SYSTEM OF MEDICINE WITH NOTES AND ADDITIONS BY HENRY HARTSHORNE, M.D., late Professor of Hygiene in the University of Penna. In three large and handsome octavo volumes, containing 3052 closely printed double-columned pages, with numerous illustrations. *Sold only by subscription.* Price per vol., in cloth, $5.00; in sheep, $6.00: half Russia, raised bands, $6.50. Per set in cloth, $15; sheep, $18; half Russia, $19.50

VOLUME I. (*just ready*) contains GENERAL DISEASES and DISEASES OF THE NERVOUS SYSTEM.
VOLUME II. (*just ready*) contains DISEASES OF RESPIRATORY and CIRCULATORY SYSTEMS.
VOLUME III. (*just ready*) contains DISEASES OF THE DIGESTIVE and BLOOD GLANDULAR SYSTEMS, OF THE URINARY ORGANS, OF THE FEMALE REPRODUCTIVE SYSTEM, and OF THE CUTANEOUS SYSTEM.

Reynolds's SYSTEM OF MEDICINE, recently completed, has acquired, since the first appearance of the first volume, the well-deserved reputation of being the work in which modern British medicine is presented in its fullest and most practical form. This could scarce be otherwise in view of the fact that it is the result of the collaboration of the leading minds of the profession, each subject being treated by some gentleman who is regarded as its highest authority—as for instance, Diseases of the Bladder by Sir HENRY THOMPSON, Malpositions of the Uterus by GRAILY HEWITT, Insanity by HENRY MAUDSLEY, Consumption by J. HUGHES BENNET, Diseases of the Spine by CHARLES BLAND RADCLIFFE, Pericarditis by FRANCIS SIBSON, Alcoholism by FRANCIS E. ANSTIE, Renal Affections by WILLIAM ROBERTS, Asthma by HYDE SALTER, Cerebral Affections by H CHARLTON BASTIAN, Gout and Rheumatism by ALFRED BARING GARROD, Constitutional Syphilis by JONATHAN HUTCHINSON, Diseases of the Stomach by WILSON FOX, Diseases of the Skin by BALMANNO SQUIRE, Affections of the Larynx by MORELL MACKENZIE, Diseases of the Rectum by BLIZARD CURLING, Diabetes by LAUDER BRUNTON, Intestinal Diseases by JOHN SYER BRISTOWE, Catalepsy and Somnambulism by THOMAS KING CHAMBERS, Apoplexy by J. HUGHLINGS JACKSON, Angina Pectoris by Professor GAIRDNER, Emphysema of the Lungs by Sir WILLIAM JENNER, etc. etc. All the leading schools in Great Britain have contributed their best men in generous rivalry, to build up this monument of medical science. St. Bartholomew's, Guy's, St. Thomas's, University College, St. Mary's, in London, while the Edinburgh, Glasgow, and Manchester schools are equally well represented, the Army Medical School at Netley, the military and naval services, and the public health boards. That a work conceived in such a spirit, and carried out under such auspices should prove an indispensable treasury of facts and experience, suited to the daily wants of the practitioner, was inevitable, and the success which it has enjoyed in England, and the reputation which it has acquired on this side of the Atlantic, have sealed it with the approbation of the two pre-eminently practical nations.

Its large size and high price having kept it beyond the reach of many practitioners in this country who desire to possess it, a demand has arisen for an edition at a price which shall render it accessible to all. To meet this demand the present edition has been undertaken. The five volumes and five thousand pages of the original have, by the use of a smaller type and double columns, been compressed into three volumes of over three thousand pages, clearly and handsomely printed, and offered at a price which renders it one of the cheapest works ever presented to the American profession.

But not only is the American edition more convenient and lower priced than the English; it is also better and more complete. Some years having elapsed since the appearance of a portion of the work, additions are required to bring up the subjects to the existing condition of science. Some diseases, also, which are comparatively unimportant in England, require more elaborate treatment to adapt the articles devoted to them to the wants of the American physician; and there are points on which the received practice in this country differs from that adopted abroad. The supplying of these deficiencies has been undertaken by HENRY HARTSHORNE, M.D., late Professor of Hygiene in the University of Pennsylvania, who has endeavored to render the work fully up to the day, and as useful to the American physician as it has proved to be to his English brethren. The number of illustrations has also been largely increased, and no effort spared to render the typographical execution unexceptionable in every respect.

Really too much praise can scarcely be given to this noble book. It is a cyclopædia of medicine written by some of the best men of Europe. It is full of useful information such as one finds frequent need of in one's daily work As a book of reference it is invaluable. It is up with the times. It is clear and concentrated in style, and its form is worthy of its famous publisher.—*Louisville Med. News*, Jan. 31, 1880.

"Reynolds' System of Medicine" is justly considered the most popular work on the principles and practice of medicine in the English language. The contributors to this work are gentlemen of well-known reputation on both sides of the Atlantic. Each gentleman has striven to make his part of the work as practical as possible, and the information contained is such as is needed by the busy practitioner.—*St. Louis Med. and Surg. Journ.*, Jan. '80.

Dr. Hartshorne has made ample additions and revisions, all of which give increased value to the volume, and render it more useful to the American practitioner. There is no volume in English medical literature more valuable, and every purchaser will, on becoming familiar with it, congratulate himself on the possession of this vast storehouse of information, in regard to so many of the subjects with which he should be familiar.—*Gaillard's Med. Journ.*, Feb. 1880.

There is no medical work which we have in times past more frequently and fully consulted when perplexed by doubts as to treatment, or by having unusual or apparently inexplicable symptoms presented to us than "Reynolds' System of Medicine." Among its contributors are gentlemen who are as well known by reputation upon this side of the Atlantic as in Great Britain, and whose right to speak with authority upon the subjects about which they have written, is recognized the world over. They have evidently striven to make their essays as practical as possible, and while these are sufficiently full to entitle them to the name of monographs, they are not loaded down with such an amount of detail as to render them wearisome to the general reader. In a word, they contain just that kind of information which the busy practitioner frequently finds himself in need of. In order that any deficiencies may be supplied, the publishers have committed the preparation of the book for the press to Dr. Henry Hartshorne, whose judicious notes distributed throughout the volume afford abundant evidence of the thoroughness of the revision to which he has subjected it.—*Am. Jour. Med. Sciences*, Jan. 1880.

BARTHOLOW (*ROBERTS*), *A.M., M.D., LL.D.*

Prof. of Materia Medica and General Therapeutics in the Jeff. Med. Coll. of Phila, etc.

A PRACTICAL TREATISE ON ELECTRICITY IN ITS APPLICATION TO MEDICINE.

In one very handsome 8vo. volume of about 270 pages, with 98 illustrations. Cloth, $2 50. (*Just ready.*)

EXTRACT FROM THE AUTHOR'S PREFACE.

I have attempted in the preparation of this work to avoid these errors; to prepare one so simple in statement that a student without previous acquaintance with the subject, may readily master the essentials; so complete as to embrace the whole subject of medical electricity, and so condensed as to be complete in a moderate compass. I have endeavored to keep constantly in view the needs of the two classes for whom the work is prepared—students and practitioners. I have assumed an entire unacquaintance with the elements of the subject as the point of departure—for I am addressing those who have either failed to acquire this preliminary knowledge, or having acquired it, find that after the lapse of years, it has become misty and confused. In the accounts of electrical phenomena I have adhered to the modes of expression with which the medical electrical text-books have made us familiar.

This book, then, must be regarded as the exposition of electricity as a remedial agent, made by a medical practitioner for the use of medical practitioners. No claim is made on the ground of pure science. It is believed, however, that the work makes an adequate presentation of the subject, regarding electricity as a remedial agent—as one of the means employed for the treatment and cure of disease.

So far as we know, the need of a clear, simple, untechnical, reliable, concise, and modern treatise upon the subject of medical electricity is only supplied by the volume under consideration. It is not too much to say that, if availed of, it will render accessible to a vast number of members of the profession a therapeutic agent of the greatest value, but which has heretofore been practically of no use whatever to them.—*Maryland Med. Journal*, June 1, 1881.

We have not yet come across a book that can compare with this in clearness and simplicity of statement. We have for a long time needed a text-book on medical electricity, condensed and yet complete, and this want has been well supplied by the distinguished author. The illustrations are elegant, and the book as a whole is a valuable addition to the collection of any student or practitioner.—*Buffalo Med. and Surg. Journal*, June, 1881.

As a whole, the book must be looked upon as an exposition of electricity for remedial purposes, written by a medical practitioner for the use of medical practitioners. From this standpoint the work is worthy of the careful study of all who desire to investigate this subject for purely practical purposes. This work meets a want of very many students and medical practitioners. We greatly err if it be not gladly welcomed by them. The author, from his long experience as a practitioner, is admirably fitted to perform the task of writing a work of this kind for this special class of men.—*Detroit Lancet*, June, 1881.

This book is expressive of careful research and a nice discrimination in the selection of such matter from that at the author's command as is best adapted for the guidance and instruction of the physician whose interest in electricity is proportionate to its practical bearing on diagnosis and treatment. It is thorough, it is accurate, it is readable, and above all is essentially utilizable, if we may use the word, and renders easy of access to the general practitioner the *modus operandi* of employing this very valuable therapeutic agent.—*N. Y. Medical Gaz.*, June 11, 1881.

MITCHELL (*S. WEIR*), *M.D.*,

Phys. to Orthopædic Hospital and the Infirmary for Dis. of the Nervous System, Phila., &c. etc.

LECTURES ON DISEASES OF THE NERVOUS SYSTEM, ESPECIALLY IN WOMEN.

In one very handsome 12mo. volume of about 250 pages, with five lithographic plates. Cloth, $1 75 (*Just Ready.*)

The life-long devotion of the author to the subjects discussed in this volume has rendered it eminently desirable that the results of his labors should be embodied for the benefit of those who may experience the difficulties connected with the treatment of this class of disease. Many of these lectures are fresh studies of hysterical affections; others treat of the modifications his views have undergone in regard to certain forms of treatment, while, throughout the whole work, he has been careful to keep in view the practical lessons of his cases.

It is a record of a number of very remarkable cases, with acute analyses and discussions, clinical, physiological, and therapeutical. It is a book to which the physician meeting with a new hysterical experience, or in doubt whether his new experience is hysterical, may well turn with a well-grounded hope of finding a parallelism; it will be a new experience, indeed, if no similar one is here recorded —*Phila. Med. Times*, June 4, 1881.

The name of the author is sufficient guarantee that these topics are ably and appreciatively discussed; suffice it to say that the principles of treatment, both hygienic and therapeutic, are clearly indicated. The articles being in the form of clinical lectures, abound in illustrative cases, and are much easier reading than a systematic treatise on the same topics.—*College and Clinical Record*, May 15, 1881.

It is needless to say that these lectures are extraordinarily rich in acute observation and sound instruction. The reputation of the author is a guarantee of that, and no reader will be disappointed. Nor can too much be said in praise of the admirable style of his medical writings, and each of these lectures reads with the finished grace of a polished essay. Indeed, the book throughout is so fascinating a one that it could not fail to be read entire by every one who begins its pages.—*Phila. Med. and Surg. Reporter*, May 7, 1881.

The book throughout is not only intensely entertaining, but it contains a large amount of rare and valuable information. Dr Mitchell has recorded not only the results of his most careful observation, but has added to the knowledge of the subjects treated by his original investigation and practical study. The book is one we can commend to all of our readers.—*Maryland Med. Journal*, May 1, 1881.

HAMILTON (*ALLAN McLANE*), *M.D.*,

Attending Physician at the Hospital for Epileptics and Paralytics, Blackwell's Island, N.Y., and at the Out-Patients' Department of the New York Hospital.

NERVOUS DISEASES; THEIR DESCRIPTION AND TREATMENT.

Second edition, thoroughly revised and rewritten. In one handsome octavo volume of about 600 pages, with numerous illustrations. (*In Press.*)

MORRIS (MALCOLM), M.D.,
Joint Lecturer on Dermatology, St. Mary's Hospital Med. School.

SKIN DISEASES, Including their Definitions, Symptoms, Diagnosis, Prognosis, Morbid Anatomy and Treatment. A Manual for Students and Practitioners.

In one 12mo. volume of over 300 pages. With illustrations. Cloth, $1 75. (*Now Ready.*)

To physicians who would like to know something about skin diseases, so that when a patient presents himself for relief they can make a correct diagnosis and prescribe a rational treatment, we unhesitatingly recommend this little book of Dr. Morris. The affections of the skin are described in a terse, lucid manner, and their several characteristics so plainly set forth that diagnosis will be easy. The treatment in each case is such as the experience of the most eminent dermatologists advise.—*Cincinnati Medical News*, April, 1880.

This is emphatically a learner's book; for we can safely say, so far as our judgment goes, that in the whole range of medical literature of a like scope, there is no book which for clearness of expression, and methodical arrangement is better adapted to promote a rational conception of dermatology, a branch confessedly difficult and perplexing to the beginner.—*St. Louis Courier of Medicine*, April, 1880.

The author of this manual has evidently a full and intimate acquaintance with the literature of dermatology, and with the most recent developments and appliances of cutaneous medicine. He has produced a plain, practical book, by aid of which, who so chooses may train his eye to the recognition of light but significant differences. The descriptions are neither too vague nor over-refined; the directions for treatment are clear and succinct.—*London Brain*, April, 1880.

The author's task has been well done and has produced one of the best recent works upon the difficult subject of which it treats; there is no work published which gives a better view of the elementary facts and principles of dermatology.—*New Orleans Medical and Surgical Journal*, April, 1880.

FOX (TILBURY), M.D., F.R.C.P., and T. C. FOX, B.A., M.R.C.S.,
Physician to the Department for Skin Diseases, University College Hospital.

EPITOME OF SKIN DISEASES. WITH FORMULÆ. FOR STUDENTS AND PRACTITIONERS.

Second edition, thoroughly revised and greatly enlarged. In one very handsome 12mo. volume of 216 pages. Cloth, $1 38.

FLINT (AUSTIN), M.D.,
Professor of the Principles and Practice of Medicine in Bellevue Hospital Med. College, N. Y.

A MANUAL OF PERCUSSION AND AUSCULTATION; of the Physical Diagnosis of Diseases of the Lungs and Heart, and of Thoracic Aneurism.

Second edition. In one handsome royal 12mo. volume: cloth, $1 63. (*Just Ready.*)

The little work before us has already become a standard one, and has become extensively adopted as a text-book. There is certainly none better. It contains the substance of the lessons which the author has for many years given, in connection with practical instruction in auscultation and percussion, to private classes, composed of medical students and practitioners.—*Cincinnati Med. News*, Feb. 1880.

BY THE SAME AUTHOR.

PHTHISIS: ITS MORBID ANATOMY, ETIOLOGY, SYMPTOMATIC EVENTS AND COMPLICATIONS, FATALITY AND PROGNOSIS, TREATMENT AND PHYSICAL DIAGNOSIS; in a series of Clinical Studies.

By AUSTIN FLINT, M.D., Prof. of the Principles and Practice of Medicine in Bellevue Hospital Med. College, New York. In one handsome octavo volume: $3 50.

BY THE SAME AUTHOR.

A PRACTICAL TREATISE ON THE DIAGNOSIS, PATHOLOGY, AND TREATMENT OF DISEASES OF THE HEART.

Second revised and enlarged edition. In one octavo volume of 550 pages, with a plate, cloth, $4.

BY THE SAME AUTHOR.

A PRACTICAL TREATISE ON THE PHYSICAL EXPLORATION OF THE CHEST AND THE DIAGNOSIS OF DISEASES AFFECTING THE RESPIRATORY ORGANS.

Second and revised edition. In one handsome octavo volume of 595 pages, cloth, $4 50.

BROWN (LENNOX), F.R.C.S. Ed.,
Senior Surgeon to the Central London Throat and Ear Hospital, etc.

THE THROAT AND ITS DISEASES.

Second American, from the Second English Edition, thoroughly revised. With one hundred Typical Illustrations in colors, and fifty wood engravings, designed and executed by the author. In one very handsome imperial octavo volume of over 350 pages. (*Preparing.*)

SEILER (CARL), M.D.,
Lecturer on Laryngoscopy at the Univ. of Penna., Chief of the Throat Dispensary at the Univ. Hospital, Phila., etc.

HANDBOOK OF DIAGNOSIS AND TREATMENT OF DISEASES OF THE THROAT AND NASAL CAVITIES.

In one handsome royal 12mo. volume, of 156 pages, with 35 illustrations; cloth, $1. (*Lately Issued.*)

We most heartily commend this book as showing sound judgment in practice, and perfect familiarity with the literature of the specialty it so ably epitomizes.—*Philada. Med. Times*, July 5, 1879.

A convenient little handbook, clear, concise, and accurate in its method, and admirably fulfilling its purpose of bringing the subject of which it treats within the comprehension of the general practitioner.—*N. C. Med. Jour.*, June, 1879.

CLINICAL OBSERVATIONS ON FUNCTIONAL NERVOUS DISORDERS. By C. HANDFIELD JONES, M.D., Physician to St. Mary's Hospital, &c. Second American Edition. In one handsome octavo volume of 348 pages, cloth, $3 25.

HILLIER'S HANDBOOK OF SKIN DISEASES, for Students and Practitioners. Second Am. Ed. In one royal 12mo. vol. of 358 pp. With illustrations. Cloth, $2 25.

BUMSTEAD (FREEMAN J.), M.D., LL.D.,

Late Professor of Venereal Diseases at the Col. of Phys. and Surg., New York, &c.

THE PATHOLOGY AND TREATMENT OF VENEREAL DISEASES.

Including the results of recent investigations upon the subject. Fourth Edition, revised and largely rewritten with the co-operation of R. W. Taylor, M.D., of New York, Prof. of Dermatology in the Univ. of Vt. In one large and handsome octavo volume of 835 pages, with 138 illustrations. Cloth, $4 75; leather, $5 75; half Russia, $6 25. (*Now Ready.*)

We have to congratulate our countrymen upon the truly valuable addition which they have made to American literature. The careful estimate of the value of the volume, which we have made, justifies us in declaring that this is the best treatise on venereal diseases in the English language, and we might add, if there is a better in any other tongue we cannot name it; there are certainly no books in which the student or the general practitioner can find such an excellent *résumé* of the literature of any topic, and such practical suggestions regarding the treatment of the various complications of every venereal disease. We take pleasure in repeating that we believe this to be the best treatise on venereal disease in the English language, and we congratulate the authors upon their brilliant addition to American medical literature.—*Chicago Med. Journal and Examiner*, February, 1880.

It is, without exception, the most valuable single work on all branches of the subject of which it treats in any language. The pathology is sound, the work is, at the same time, in the highest degree practical, and the hints that he will get from it for the management of any one case, at all obscure or obstinate, will more than repay him for the outlay.—*Archives of Medicine*, April, 1880.

This now classical work on venereal disease comes to us in its fourth edition rewritten, enlarged, and materially improved in every way. Dr. Taylor, as we had every reason to expect, has performed this part of his work with unusual excellence. We feel that what has been written has done but scanty justice to the merits of this truly great treatise.—*St. Louis Courier of Medicine*, Feb. 1880.

We find that we have here practically a new book—that the statement of the title-page, as to the fact that it has been largely rewritten, is a sufficiently modest announcement for the important changes in the text. After a thorough examination of the present edition, we can assert confidently that the enormous labor we have described has been here most faithfully and conscientiously performed.—*Amer. Journ. Med. Sci.*, Jan. 1880.

It is one of the best general treatises on venereal diseases with which we are acquainted, and is especially to be recommended as a guide to the treatment of syphilis.—*London Practitioner*, March, 1880.

GROSS (SAMUEL W.), A.M., M.D.,

Lecturer on Genito-Urinary and Venereal Diseases in the Jefferson Medical College, Phila.

A PRACTICAL TREATISE ON IMPOTENCE, STERILITY AND ALLIED DISORDERS OF THE MALE SEXUAL ORGANS.

In one very handsome octavo volume of 174 pages, with 16 illustrations. Cloth, $1 50. (*Just Ready.*)

EXTRACT FROM THE AUTHOR'S PREFACE.

"My aim has been to supply, in a compact form, practical and strictly scientific information, especially adapted to the wants of the general practitioner, in regard to a class of common and grave disorders, upon the correction of which so much of human happiness depends. In the chapter on Sterility, the abnormal conditions of the semen and the causes which deprive it of its fecundating properties are fully considered—a portion of the work intended to supplement the subject of sterility in the female. From answers to letters addressed to many of the most prominent writers in this country on gynæcology, I find that, with few exceptions, the woman alone commands attention in unfruitful marriages. The importance of examining the husband before subjecting the wife to operation will be best appreciated when I state that he is, as a rule, at fault in at least one example in every six."

JULLERIER (A.), *Surgeon to the Hôpital du Midi.* and BUMSTEAD (FREEMAN J.), *Professor of Venereal Diseases in the College of Physicians and Surgeons, N. Y.*

AN ATLAS OF VENEREAL DISEASES.

Translated and Edited by FREEMAN J. BUMSTEAD. In one large imperial 4to. volume of 328 pages, double-columns, with 26 plates, containing about 150 figures, beautifully colored, many of them the size of life; strongly bound in cloth, $17 00; also, in five parts, stout wrappers, at $3 per part.

Anticipating a very large sale for this work, it is offered at the very low price of THREE DOLLARS a Part, thus placing it within the reach of all who are interested in this department of practice. Gentlemen desiring early impressions of the plates would do well to order it without delay. A specimen of the plates and text sent free by mail, on receipt of 25 cents.

LEE'S LECTURES ON SYPHILIS AND SOME FORMS OF LOCAL DISEASE AFFECTING PRINCIPALLY THE ORGANS OF GENERATION. In one handsome octavo volume; cloth, $2 25.

CONDIE'S PRACTICAL TREATISE ON THE DISEASES OF CHILDREN. Sixth edition, revised and augmented. In one large octavo volume of nearly 800 closely-printed pages, cloth, $5 25; leather, $6 25.

WILSON'S STUDENT'S BOOK OF CUTANEOUS MEDICINE and DISEASES OF THE SKIN. In one very handsome royal 12mo volume. $3 50.

CHAMBERS'S MANUAL OF DIET AND REGIMEN IN HEALTH AND SICKNESS. In one handsome octavo volume. Cloth, $2 75.

BASHAM ON RENAL DISEASES: a Clinical Guide to their Diagnosis and Treatment. With Illustrations. In one 12mo. vol. of 304 pages, cloth, $2 00.

LECTURES ON THE STUDY OF FEVER. By A. HUDSON, M.D., M.R.I.A., Physician to the Meath Hospital. In one vol. 8vo., cloth, $2 50.

A TREATISE ON FEVER. By ROBERT D. LYONS, K.C.C. In one octavo volume of 362 pages, cloth $2 25.

HILL ON SYPHILIS AND LOCAL CONTAGIOUS DISORDERS. In one handsome octavo volume; cloth $3 25.

SMITH'S PRACTICAL TREATISE ON THE WASTING DISEASES OF INFANCY AND CHILDHOOD. Second American, from the Second revised and enlarged English edition. In one handsome octavo volume, cloth, $2 50.

LA ROCHE ON PNEUMONIA. 1 vol. 8vo., cloth, of 500 pages. Price, $3 00.

SMITH (*J. LEWIS*), *M.D.*,

Clinical Professor of Diseases of Children in the Bellevue Hospital Med. College, N.Y.

A COMPLETE PRACTICAL TREATISE ON THE DISEASES OF CHILDREN. Fifth Edition, thoroughly revised and rewritten. In one handsome octavo volume of 836 pages, with illustrations. Cloth, $4 50; leather, $5 50; very handsome half Russia, raised bands, $6. (*Just Ready.*)

The opportunity afforded the author by the call for a new edition of his treatise on the Diseases of Children has been taken advantage of to render the volume in every respect worthy a continuance of the profession's confidence with which it has been favored in the past. Many portions of the work have been entirely rewritten, several additional diseases treated of, and much new matter introduced; but by the employment of a more condensed style of letter, the size of the work has not been materially enlarged. It will be observed that the very moderate price of the previous edition has not been increased.

KEATING (*JOHN M.*), *M.D.*,

Lecturer on the Diseases of Children at the University of Pennsylvania, etc.

THE MOTHER'S GUIDE IN THE MANAGEMENT AND FEEDING OF INFANTS. In one handsome 12mo. vol. of 118 pages. Cloth, $1 00. (*Now Ready.*)

The title of this little book is well chosen, and Dr. Keating has written a work which should be read, and its precepts followed by every intelligent mother in this country. It is free from all technical terms, the language is clear and distinct, and so carefully written that it cannot fail to become popular. It has always been a mooted question how far it is well to instruct the public, but works like this one will aid the physician immensely, for it saves the time he is constantly giving his patients in instructing them on the subjects here dwelt so thoroughly and practically upon. Dr. Keating has written a practical book, has carefully avoided unnecessary repetition, and, I think, successfully instructed the mother in such details of the treatment of her child as devolve upon her; he has studiously omitted giving prescriptions, and instructs the mother when to call upon the doctor, as his duties are totally distinct from hers.—*American Journal of Obstetrics*, October, 1881.

WEST (*CHARLES*), *M.D.*,

Physician to the Hospital for Sick Children, London, &c.

LECTURES ON THE DISEASES OF INFANCY AND CHILDHOOD. Fifth American from the Sixth revised and enlarged English edition. In one large and handsome octavo volume of 678 pages. Cloth, $4 50; leather, $5 50.

BY THE SAME AUTHOR. (*Lately Issued.*)

ON SOME DISORDERS OF THE NERVOUS SYSTEM IN CHILDHOOD; being the Lumleian Lectures delivered at the Royal College of Physicians of London, in March, 1871. In one volume small 12mo., cloth, $1 00.

BY THE SAME AUTHOR.

LECTURES ON THE DISEASES OF WOMEN. Third American, from the Third London edition. In one neat octavo volume of about 550 pages, cloth, $3 75; leather, $4 75.

SWAYNE (*JOSEPH GRIFFITHS*), *M.D.*,

Physician-Accoucheur to the British General Hospital, &c.

OBSTETRIC APHORISMS FOR THE USE OF STUDENTS COMMENCING MIDWIFERY PRACTICE. Second American, from the Fifth and Revised London Edition, with Additions by E. R. HUTCHINS, M.D. With Illustrations. In one neat 12mo. volume. Cloth, $1 25.

CHURCHILL ON THE PUERPERAL FEVER AND OTHER DISEASES PECULIAR TO WOMEN. 1 vol. 8vo., pp. 450, cloth. $2 50.

DEWEES'S TREATISE ON THE DISEASES OF FEMALES. With illustrations. Eleventh Edition, with the Author's last improvements and corrections. In one octavo volume of 536 pages, with plates, cloth. $3 00.

MEIGS ON THE NATURE, SIGNS AND TREATMENT OF CHILDBED FEVER. 1 vol. 8vo., pp. 365. cloth. $2 00.

ASHWELL'S PRACTICAL TREATISE ON THE DISEASES PECULIAR TO WOMEN. Third American, from the Third and revised London edition. 1 vol. 8vo., pp. 528, cloth. $3 50.

WINCKEL (*F.*),

Professor and Director of the Gynæcological Clinic in the University of Rostock.

A COMPLETE TREATISE ON THE PATHOLOGY AND TREATMENT OF CHILDBED, for Students and Practitioners. Translated, with the consent of the author, from the Second German Edition, by JAMES READ CHADWICK, M.D. In one octavo volume. Cloth, $4 00.

MONTGOMERY'S EXPOSITION OF THE SIGNS AND SYMPTOMS OF PREGNANCY. With two exquisite colored plates, and numerous wood-cuts. In 1 vol. 8vo., of nearly 600 pp., cloth, $3 75.

RIGBY'S SYSTEM OF MIDWIFERY. With notes and Additional Illustrations. Second American edition. One volume octavo, cloth, 422 pages, $2 50.

THOMAS (*T. GAILLARD*), *M.D.*,

Professor of Obstetrics, &c., in the College of Physicians and Surgeons, N. Y., &c

A PRACTICAL TREATISE ON THE DISEASES OF WOMEN. Fifth

Edition, thoroughly revised and rewritten. In one large and handsome octavo volume of over 800 pages, with 266 illustrations. Cloth, $5; leather, $6; very handsome half Russia, raised bands, $6 50. (*Just Ready.*)

The author has taken advantage of the opportunity afforded by the call for a new edition of this work to render it worthy a continuance of the very remarkable favor with which it has been received. Every portion of the work has been carefully revised, very much of it has been rewritten, and additions and alterations introduced wherever the advance of science and the increased experience of the author have shown them desirable. At the same time special care has been exercised to avoid undue increase in the size of the volume.. To accommodate the numerous additions a more condensed but very clear letter has been used, notwithstanding which, the number of pages has been increased by more than fifty. The series of illustrations has been extensively changed; many which seemed to be superfluous have been omitted, and a large number of new and superior drawings have been inserted. In its improved form, therefore, it is hoped that the volume will maintain the character it has acquired of a standard authority on every detail of its important subject.

An examination of the work will satisfy that it is one of great merit. It is not a mere compilation from other works, but is the fruit of the ripe thought, sound judgment, and critical observations of a learned, scientific man. It is a treasury of knowledge of the department of medicine to which it is devoted In its present revised state it certainly holds a foremost position as a gynæcological work, and will continue to be regarded as a standard authority —*Cincinnati Med. News*, Dec. 1880.

This work needs no introduction to any of the civilized nations of the world. The edition before us adds to the strength of former volumes. With the wisdom of a master teacher he here gives the results that, in his judgment, are most trustworthy at the present time. In its own place it has no rival, because the author is the best teacher on this subject to the masses of the profession As hitherto this work will be the text-book on diseases of women We only wish that in other branches of medicine as capable teachers could be found to write our text-books.—*Detroit Lancet*, Jan. 1881.

Since its first appearance, twelve years ago, until the present day, it has held a position of high regard, and is generally conceded to be one of the most practical and trustworthy volumes yet presented to the physician and student in the department of gynæcology. The work embodies not only its author's large experience, but reflects his careful study among other authorities in this branch, both at home and abroad Dr. Thomas is an able and conscientious teacher. His writings convey his meaning in the same practical and instructive manner. The last edition of this work is fresh from his pen, with decided changes and improvements over former editions. His book presents generally accepted facts, and as a guide to the student is more useful and reliable than any work in the language on diseases of women. This last edition will add new laurels to those already won. — *Md. Med. Journ.*, Nov. 15, 1880.

It has been enlarged and carefully revised. The author has brought it fully abreast with the times, and as the wave of gynæcological progression has been widespread and rapid during the twelve years that have elapsed since the issue of the first edition, one can conceive of the great improvement this edition must be upon the earlier. It is a condensed encyclopædia of gynæcological medicine. The style of arrangement, the masterly manner in which each subject is treated, and the honest convictions derived from probably the largest clinical experience in that specialty of any in this country, all serve to commend it in the highest terms to the practitioner. —*Nashville Journ. of Med. and Surg.*, Jan. 1881.

EDIS (*ARTHUR W.*), *M.D. Lond., F.R.C.P., M.R.C.S.*

Assist. Obstetric Physician to Middlesex Hospital, late Physician to British Lying-in Hospital.

THE DISEASES OF WOMEN. Including their Pathology, Causation, Symptoms, Diagnosis, and Treatment.

A manual for Students and Practitioners. In one handsome octavo volume with 149 illustrations. (*Shortly.*)

BARNES (*ROBERT*), *M.D., F.R.C.P.*,

Obstetric Physician to St. Thomas's Hospital, &c.

A CLINICAL EXPOSITION OF THE MEDICAL AND SURGICAL DISEASES OF WOMEN.

Second American, from the Second Enlarged and Revised English Edition. In one handsome octavo volume, of 784 pages, with 181 illustrations. Cloth, $4 50; leather, $5 50; half Russia, $6. (*Lately Issued.*)

Dr. Barnes stands at the head of his profession in the old country, and it requires but scant scrutiny of his book to show that it has been sketched by a master. It is plain, practical common sense; shows very deep research without being pedantic; is eminently calculated to inspire enthusiasm without inculcating rashness; points out the dangers to be avoided as well as the success to be achieved in the various operations connected with this branch of medicine; and will do much to smooth the rugged path of the young gynæcologist and relieve the perplexity of the man of mature years. — *Canadian Journ. of Med. Science*, Nov. 1878.

Dr. Barnes's work is one of a practical character, largely illustrated from cases in his own experience, but by no means confined to such, as will be learned from the fact that he quotes from no less than 625 medical authors in numerous countries. Coming from such an author, it is not necessary to say that the work is a valuable one, and should be largely consulted by the profession.—*Am. Supp. Obstetrical Journ. Gt. Britain and Ireland*, Oct. 1878.

HODGE (*HUGH L.*), *M.D.*,

Emeritus Professor of Obstetrics, &c., in the University of Pennsylvania.

ON DISEASES PECULIAR TO WOMEN; including Displacements of the Uterus.

With original illustrations. Second edition, revised and enlarged. In one beautifully printed octavo volume of 531 pages, cloth, $4 50.

EMMET (*THOMAS ADDIS*), *M.D.*,

Surgeon to the Woman's Hospital, New York, etc.

THE PRINCIPLES AND PRACTICE OF GYNÆCOLOGY, for the use of Students and Practitioners of Medicine. Second Edition. Thoroughly Revised. In one large and very handsome octavo volume of 875 pages, with 133 illustrations. Cloth, $5; leather, $6; half Russia, raised bands, $6 50. (*Just Ready.*)

PREFACE TO THE SECOND EDITION.

The unusually rapid exhaustion of a large edition of this work, while flattering to the author as an evidence that his labors have proved acceptable, has in a great measure heightened his sense of responsibility. He has therefore endeavored to take full advantage of the opportunity afforded to him for its revision. Every page has received his earnest scrutiny; the criticisms of his reviewers have been carefully weighed; and while no marked increase has been made in the size of the volume, several portions have been rewritten, and much new matter has been added. In this minute and thorough revision, the labor involved has been much greater than is perhaps apparent in the results, but it has been cheerfully expended in the hope of rendering the work more worthy of the favor which has been accorded to it by the profession.

In no country of the world has gynæcology received more attention than in America. It is, then, with a feeling of pleasure that we welcome a work on diseases of women from so eminent a gynæcologist as Dr. Emmet, and the work is essentially clinical, and leaves a strong impress of the author's individuality. To criticise, with the care it merits, the book throughout, would demand far more space than is at our command. In parting, we can say that the work teems with original ideas, fresh and valuable methods of practice, and is written in a clear and elegant style, worthy of the literary reputation of the country of Longfellow and Oliver Wendell Holmes.—*Brit. Med. Journ.* Feb. 21, 1880.

No gynæcological treatise has appeared which contains an equal amount of original and useful matter; nor does the medical and surgical history of America include a book more novel and useful. The tabular and statistical information which it contains is marvellous, both in quantity and accuracy, and cannot be otherwise than invaluable to future investigators. It is a work which demands not careless reading but profound study. Its value as a contribution to gynæcology is, perhaps, greater than that of all previous literature on the subject combined.—*Chicago Med. Gaz.*, April 5, 1880

The wide reputation of the author makes its publication an event in the gynæcological world; and a glance through its pages shows that it is a work to be studied with care. . . . It must always be a work to be carefully studied and frequently consulted by those who practise this branch of our profession.—*Lond. Med. Times and Gaz.*, Jan. 10, 1880.

The character of the work is too well known to require extended notice—suffice it to say that no recent work upon any subject has attained such great popularity so rapidly. As a work of general reference upon the subject of Diseases of Women it is invaluable. As a record of the largest clinical experience and observation it has no equal. No physician who pretends to keep up with the advances of this department of medicine can afford to be without it.—*Nashville Journ. of Medicine and Surgery*, May, 1880.

DUNCAN (*J. MATTHEWS*), *M.D., LL.D., F.R.S.E., etc.*

CLINICAL LECTURES ON THE DISEASES OF WOMEN, Delivered in Saint Bartholomew's Hospital. In one very neat octavo volume of 173 pages. Cloth, $1 50. (*Just Ready.*)

They are in every way worthy of their author; indeed, we look upon them as among the most valuable of his contributions. They are all upon matters of great interest to the general practitioner. Some of them deal with subjects that are not, as a rule, adequately handled in the text-books; others of them, while bearing upon topics that are usually treated of at length in such works, yet bear such a stamp of individuality that, if widely read, as they certainly deserve to be, they cannot fail to exert a wholesome restraint upon the undue eagerness with which many young physicians seem bent upon following the wild teachings which so infest the gynæcology of the present day.—*N. Y. Med. Journ.*, March, 1880.

The author is a remarkably clear lecturer, and his discussion of symptoms and treatment is full and suggestive. It will be a work which will not fail to be read with benefit by practitioners as well as by students.—*Phila. Med. and Surg. Reporter*, Feb. 7, 1880.

We have read this book with a great deal of pleasure. It is full of good things. The hints on pathology and treatment scattered through the book are sound, trustworthy, and of great value. A healthy scepticism, a large experience, and a clear judgment are everywhere manifest. Instead of bristling with advice of doubtful value and unsound character, the book is in every respect a safe guide.—*The London Lancet*, Jan. 21, 1880.

RAMSBOTHAM (*FRANCIS H.*), *M.D.*

THE PRINCIPLES AND PRACTICE OF OBSTETRIC MEDICINE AND SURGERY, in reference to the Process of Parturition. A new and enlarged edition, thoroughly revised by the author. With additions by W. V. KEATING, M. D., Professor of Obstetrics, &c., in the Jefferson Medical College, Philadelphia. In one large and handsome imperial octavo volume of 650 pages, strongly bound in leather, with raised bands; with sixty-four beautiful plates, and numerous wood-cuts in the text, containing in all nearly 200 large and beautiful figures. $7 00

PARRY (*JOHN S.*), *M.D.*,

Obstetrician to the Philadelphia Hospital, Vice-Pres. of the Obstet. Society of Philadelphia.

EXTRA-UTERINE PREGNANCY: ITS CLINICAL HISTORY, DIAGNOSIS, PROGNOSIS AND TREATMENT. In one handsome octavo volume. Cloth, $2 50.

TANNER (*THOMAS H.*), *M.D.*

ON THE SIGNS AND DISEASES OF PREGNANCY. First American from the Second and Enlarged English Edition. With four colored plates and illustrations on wood. In one handsome octavo volume of about 500 pages, cloth, $4 25.

LEISHMAN (*WILLIAM*), *M.D.*,

Regius Professor of Midwifery in the University of Glasgow, &c.

A SYSTEM OF MIDWIFERY, INCLUDING THE DISEASES OF PREGNANCY AND THE PUERPERAL STATE. Third American edition, revised by the Author, with additions by JOHN S. PARRY, M.D., Obstetrician to the Philadelphia Hospital, &c. In one large and very handsome octavo volume, of 733 pages, with over two hundred illustrations. Cloth, $4 50; leather, $5 50; half Russia, $6. (*Just Ready.*)

Few works on this subject have met with as great a demand as this one appears to have. To judge by the frequency with which its author's views are quoted, and its statements referred to in obstetrical literature, one would judge that there are few physicians devoting much attention to obstetrics who are without it. The author is evidently a man of ripe experience and conservative views, and in no branch of medicine are these more valuable than in this.—*New Remedies*, Jan. 1880.

We gladly welcome the new edition of this excellent text-book of midwifery. The former editions have been most favorably received by the profession on both sides of the Atlantic. In the preparation of the present edition the author has made such alterations as the progress of obstetrical science seems to require, and we cannot but admire the ability with which the task has been performed. We consider it an admirable text-book for students during their attendance upon lectures, and have great pleasure in recommending it. As an exponent of the midwifery of the present day it has no superior in the English language.—*Canada Lancet*, Jan. 1880.

To the American student the work before us must prove admirably adapted, complete in all its parts, essentially modern in its teachings and with demonstrations noted for clearness and precision, it will gain in favor and be recognized as a work of standard merit. The work cannot fail to be popular, and is cordially recommended.—*N. O. Med. and Surg. Journ.*, March, 1880.

PLAYFAIR (*W. S.*), *M.D., F.R.C.P.*,

Professor of Obstetric Medicine in King's College, etc. etc.

A TREATISE ON THE SCIENCE AND PRACTICE OF MIDWIFERY. Third American edition, revised by the author. Edited, with additions, by ROBERT P. HARRIS, M.D. In one handsome octavo volume of about 700 pages, with nearly 200 illustrations. Cloth, $4; leather, $5; half Russia, $5 50. (*Just Ready.*)

The medical profession has now the opportunity of adding to their stock of standard medical works one of the best volumes on midwifery ever published. The subject is taken up with a master hand. The part devoted to labor in all its various presentations, the management and results, is admirably arranged, and the views entertained will be found essentially modern, and the opinions expressed trustworthy. The work abounds with plates, illustrating various obstetrical positions; they are admirably wrought, and afford great assistance to the student.—*N. O. Med. and Surg. Journ.*, March, 1880.

If inquired of by a medical student what work on obstetrics we should recommend for him, as *par excellence*, we would undoubtedly advise him to choose Playfair's. It is of convenient size, but what is of chief importance, its treatment of the various subjects is concise and plain. While the discussions and descriptions are sufficiently elaborate to render a very intelligent idea of them, yet all details not necessary for a full understanding of the subject are omitted.—*Cincinnati Med. News*, Jan. 1880.

The rapidity with which one edition of this work follows another is proof alike of its excellence and of the estimate that the profession has formed of it. It is indeed so well known and so highly valued that nothing need be said of it as a whole. All things considered, we regard this treatise as the very best on Midwifery in the English language.—*N. Y. Medical Journal*, May, 1880.

It certainly is an admirable exposition of the Science and Practice of Midwifery. Of course the additions made by the American editor, Dr. R. P. Harris, who never utters an idle word, and whose studious researches in some special departments of obstetrics are so well known to the profession, are of great value.—*The American Practitioner*, April, 1880.

BARNES (*FANCOURT*), *M.D.*,

Physician to the General Lying-in Hospital, London.

A MANUAL OF MIDWIFERY FOR MIDWIVES AND MEDICAL STUDENTS. With 50 illustrations. In one neat royal 12mo. volume of 200 pages; cloth, $1 25. (*Now Ready.*)

PARVIN (*THEOPHILUS*), *M.D.*,

Prof. of Obstetrics and of the Med. and Surg. Diseases of Women in the Med. Coll. of Indiana.

A TREATISE ON MIDWIFERY. In one very handsome octavo volume of about 550 pages, with numerous illustrations. (*Preparing.*)

HODGE (*HUGH L.*), *M.D.*,

Emeritus Professor of Midwifery, &c., in the University of Pennsylvania, &c.

THE PRINCIPLES AND PRACTICE OF OBSTETRICS. Illustrated with large lithographic plates containing one hundred and fifty-nine figures from original photographs, and with numerous wood-cuts. In one large and beautifully printed quarto volume of 550 double-columned pages, strongly bound in cloth, $14.

The work of Dr. Hodge is something more than a simple presentation of his particular views in the department of Obstetrics; it is something more than an ordinary treatise on midwifery; it is, in fact, a cyclopædia of midwifery. He has aimed to embody in a single volume the whole science and art of Obstetrics. An elaborate text is combined with accurate and varied pictorial illustrations, so that no fact or principle is left unstated or unexplained.—*Am. Med. Times*, Sept. 3, 1864.

*** Specimens of the plates and letter-press will be forwarded to any address, free by mail, on receipt of six cents in postage stamps.

CHADWICK (*JAMES R.*), *A.M., M.D.*

A MANUAL OF THE DISEASES PECULIAR TO WOMEN. In one neat volume, royal 12mo., with illustrations. (*Preparing.*)

HAMILTON (FRANK H.) M.D., LL.D.,

Surgeon to the Bellevue Hospital, New York.

A PRACTICAL TREATISE ON FRACTURES AND DISLOCATIONS

Sixth Edition, thoroughly revised, and much improved. In one very handsome octavo volume of over 900 pages, with 352 illustrations. Cloth, $5 50; leather, $6 50; half Russia, raised bands, $7 00. (*Just Ready.*)

So many kind expressions of welcome have been showered upon each successive edition of this valuable treatise, that scarcely anything remains for us to do but to extend the customary cordial greeting. It is the only complete work on the subject of Fractures in the English language We congratulate the accomplished author on the deserved success of his work, and hope that he may live to have many succeeding editions pass under his skilled supervision.—*Phila. Coll. and Clin. Record*, Nov. 15, 1880.

Universal verdict has pronounced it, humanly speaking, a perfect treatise upon this subject. As it is the only complete and illustrated work in any language treating of fractures and dislocations, it is safe to affirm that every wide-awake surgeon and general practitioner will regard it as indispensable to the safe and pleasant conduct of their professional work.—*Detroit Lancet*, Nov. 18, 1880.

Dr Hamilton has devoted great labor to the study of these subjects. His large experience, extended research, and patient investigation have made him one of the highest authorities among living writers in this branch of surgery. This work is systematic and practical in its arrangement, and presents its subject matter clearly and forcibly to the reader or student.—*Maryland Medical Journal*, Nov. 15, 1880.

The only complete work on its subject in the English tongue, and, indeed, may now be said to be the only work of its kind in any tongue. It would require an exceedingly critical examination to detect in it any particulars in which it might be improved. The work is a monument to American surgery, and will long serve to keep green the memory of its venerable author.—*Michigan Med. News*, Nov. 10, 1881.

ASHHURST (JOHN, Jr.), M.D.,

Prof. of Clinical Surgery, Univ of Pa., Surgeon to the Episcopal Hospital, Philadelphia.

THE PRINCIPLES AND PRACTICE OF SURGERY.

Second Edition, enlarged and revised. In one very large and handsome octavo volume of over 1000 pages, with 542 illustrations. Cloth, $6; leather, $7; half Russia, $7 50. (*Just Issued.*)

Conscientiousness and thoroughness are two very marked traits of character in the author of this book. Out of these traits largely has grown the success of his mental fruit in the past, and the present offer seems in no wise an exception to what has gone before. The general arrangement of the volume is the same as in the first edition, but every part has been carefully revised, and much new matter added.—*Phila. Med. Times*, Feb. 1, 1879.

The favorable reception of the first edition is a guarantee of the popularity of this edition, which is fresh from the editor's hands with many enlargements and improvements. The author of this work is deservedly popular as an editor and writer, and his contributions to the literature of surgery have gained for him wide reputation. The volume now offered the profession will add new laurels to those already won by previous contributions. We can only add that the work is well arranged, filled with practical matter, and contains in brief and clear language all that is necessary to be learned by the student of surgery whilst in attendance upon lectures, or the general practitioner in his daily routine practice.—*Md. Med. Journal*, Jan. 1879.

The fact that this work has reached a second edition so very soon after the publication of the first one, speaks more highly of its merits than anything we might say in the way of commendation. It seems to have immediately gained the favor of students and physicians.—*Cincin. Med. News*, Jan. '79.

We have previously spoken of Dr. Ashhurst's work in terms of praise. We wish to reiterate those terms here, and to add that no more satisfactory representation of modern surgery has yet fallen from the press. In point of judicial fairness, of power of condensation, of accuracy and conciseness of expression and thoroughly good English, Prof. Ashhurst has no superior among the surgical writers in America.—*Am. Practitioner*, Jan. 1879.

STIMSON (LEWIS A.), A.M., M.D.,

Surgeon to the Presbyterian Hospital.

A MANUAL OF OPERATIVE SURGERY.

In one very handsome royal 12mo. volume of about 500 pages, with 332 illustrations; cloth, $2 50.

The work before us is a well printed, profusely illustrated manual of over four hundred and seventy pages. The novice, by a perusal of the work, will gain a good idea of the general domain of operative surgery, while the practical surgeon has presented to him within a very concise and intelligible form the latest and most approved selections of operative procedure. The precision and conciseness with which the different operations are described enable the author to compress an immense amount of practical information in a very small compass.—*N. Y. Medical Record*, Aug. 3, 1878.

This volume is devoted entirely to operative surgery, and is intended to familiarize the student with the details of operations and the different modes of performing them. The work is handsomely illustrated, and the descriptions are clear and well drawn. It is a clever and useful volume; every student should possess one. The preparation of this work does away with the necessity of pondering over larger works on surgery for descriptions of operations, as it presents in a nut-shell just what is wanted by the surgeon without an elaborate search to find it.—*Md. Med Journal*, Aug. 1878.

The author's conciseness and the repleteness of the work with valuable illustrations entitle it to be classed with the text-books for students of operative surgery, and as one of reference to the practitioner. —*Cincinnati Lancet and Clinic*, July 27, 1878.

SKEY'S OPERATIVE SURGERY. In 1 vol. 8vo. cl., of 650 pages; with about 100 wood-cuts. $3 25.

COOPER'S LECTURES ON THE PRINCIPLES AND PRACTICE OF SURGERY. In 1 vol. 8vo. cl'h, 750 p. $2.

GIBSON'S INSTITUTES AND PRACTICE OF SURGERY. Eighth edit'n, improved and altered. With thirty-four plates. In two handsome octavo volumes, about 1000 pp., leather, raised bands. $6 50.

THE PRINCIPLES AND PRACTICE OF SURGERY. By WILLIAM PIRRIE, F.R.S.E., Professor of Surgery in the University of Aberdeen. Edited by JOHN NEILL, M.D., Professor of Surgery in the Penna. Medical College, Surg'n to the Pennsylvania Hospital, &c. In one very handsome octavo vol. of 780 pages, with 316 illustrations, cloth, $3 75.

MILLER'S PRINCIPLES OF SURGERY. Fourth American, from the Third Edinburgh Edition. In one large 8vo. vol. of 700 pages, with 340 illustrations, cloth, $3 75.

MILLER'S PRACTICE OF SURGERY. Fourth American, from the last Edinburgh Edition Revised by the American editor. In one large 8vo. vol. of nearly 700 pages, with 364 illustrations: cloth, $3 75.

GROSS (SAMUEL D.), M.D.,

Professor of Surgery in the Jefferson Medical College of Philadelphia.

A SYSTEM OF SURGERY: Pathological, Diagnostic, Therapeutic and Operative. Illustrated by upwards of Fourteen Hundred Engravings. Fifth edition, carefully revised and improved. In two large and beautifully printed imperial octavo volumes of about 2300 pp., strongly bound in leather, with raised bands, $15; half Russia, raised bands, $16.

We have seldom read a work with the practical value of which we have been more impressed. Every chapter is so concisely put together, that the busy practitioner, when in difficulty, can at once find the information he requires. His work is cosmopolitan, the surgery of the world being fully represented in it. The work, in fact, is so historically unprejudiced, and so eminently practical, that it is almost a false compliment to say that we believe it to be destined to occupy a foremost place as a work of reference, while a system of surgery like the present system of surgery is the practice of surgeons. The printing and binding of the work is unexceptionable; indeed, it contrasts, in the latter respect, remarkably with English medical and surgical cloth-bound publications, which are generally so wretchedly stitched as to require re-binding before they are any time in use.—*Dub. Journ. of Med. Sci.*, March, 1874.

Dr. Gross's Surgery, a great work, has become still greater, both in size and merit, in its most recent form. The difference in actual number of pages is not more than 130, but the size of the page having been increased to what we believe is technically termed "elephant," there has been room for considerable additions, which, together with the alterations, are improvements.—*Lond. Lancet*, Nov. 16, 1872.

It combines, as perfectly as possible, the qualities of a text-book and work of reference. We think this last edition of Gross's "Surgery," will confirm his title of "*Primus inter Pares.*" It is learned, scholar-like, methodical, precise, and exhaustive. We scarcely think any living man could write so complete and faultless a treatise, or comprehend more solid, instructive matter in the given number of pages. The labor must have been immense, and the work gives evidence of great powers of mind, and the highest order of intellectual discipline and methodical disposition and arrangement of acquired knowledge and personal experience.—*N.Y. Med. Journ.*, Feb. 1873.

As a whole, we regard the work as the representative "System of Surgery" in the English language.—*St. Louis Medical and Surg. Journ.*, Oct. 1872.

The two magnificent volumes before us afford a very complete view of the surgical knowledge of the day. Some years ago we had the pleasure of presenting the first edition of Gross's Surgery to the profession as a work of unrivalled excellence; and now we have the result of years of experience, labor, and study, all condensed upon the great work before us. And to students or practitioners desirous of enriching their library with a treasure of reference, we can simply commend the purchase of these two volumes of immense research.—*Cincinnati Lancet and Observer*, Sept. 1872.

A complete system of surgery—not a mere text-book of operations, but a scientific account of surgical theory and practice in all its departments.—*Brit. and For. Med. Chir. Rev.*, Jan. 1873.

BY THE SAME AUTHOR.

A PRACTICAL TREATISE ON THE DISEASES, INJURIES and Malformations of the Urinary Bladder, the Prostate Gland and the Urethra. Third Edition, thoroughly Revised and Condensed, by SAMUEL W. GROSS, M.D., Surgeon to the Philadelphia Hospital. In one handsome octavo volume of 574 pages, with 170 illustrations: cloth, $4 50.

For reference and general information, the physician or surgeon can find no work that meets their necessities more thoroughly than this, a revised edition of an excellent treatise, and no medical library should be without it. Replete with handsome illustrations and good ideas, it has the unusual advantage of being easily comprehended, by the reasonable and practical manner in which the various subjects are systematized and arranged. We heartily recommend it to the profession as a valuable addition to the important literature of diseases of the urinary organs.—*Atlanta Med. Journ.*, Oct. 1876.

It is with pleasure we now again take up this old work in a decidedly new dress. Indeed, it must be regarded as a new book in very many of its parts. The chapters on "Diseases of the Bladder," "Prostate Body," and "Lithotomy," are splendid specimens of descriptive writing; while the chapter on "Stricture" is one of the most concise and clear that we have ever read.—*New York Med. Journ.*, Nov. 1876.

BY THE SAME AUTHOR.

A PRACTICAL TREATISE ON FOREIGN BODIES IN THE AIR-PASSAGES. In 1 vol. 8vo., with illustrations, pp. 468, cloth, $2 75.

COLEMAN (ALFRED), L.R.C.P., F.R.C.S., L.D.S., etc.

Senior Dental Surgeon and Lecturer on Dental Surgery to St. Bartholomew's Hospital and the Dental College of London.

A MANUAL OF DENTAL SURGERY AND PATHOLOGY. Thoroughly revised and adapted to the use of American students, by Thomas C. Stellwagen, M.A., M.D., D.D.S., Professor of Physiology at the Philadelphia Dental College. In one handsome volume with about 450 illustrations. (*In Press.*)

DRUITT (ROBERT), M.R.C.S., &c.

THE PRINCIPLES AND PRACTICE OF MODERN SURGERY. A new and revised American, from the Eighth enlarged and improved London edition. Illustrated with four hundred and thirty-two wood engravings. In one very handsome octavo volume, of nearly 700 large and closely printed pages, cloth, $4 00; leather, $5 00.

In Mr. Druitt's book, though containing only some seven hundred pages, both the principles and the practice of surgery are treated, and so clearly and perspicuously, as to elucidate every important topic. We have examined the book most thoroughly, and can say that this success is well merited. His book, moreover, possesses the inestimable advantages of having the subjects perfectly well arranged and classified and of being written in a style at once clear and succinct.—*Am. Journal of Med. Sciences.*

ASHTON ON THE DISEASES, INJURIES, AND MALFORMATIONS OF THE RECTUM AND ANUS: with remarks on Habitual Constipation. Second American, from the Fourth and enlarged London Edition. With illustrations. In one 8vo. vol. of 287 pages, cloth, $3 25.

SARGENT ON BANDAGING AND OTHER OPERATIONS OF MINOR SURGERY. New edition, with an additional chapter on Military Surgery. One 12mo. vol. of 383 pages with 184 wood-cuts. Cloth, $1 75.

HOLMES (TIMOTHY), M.A.,

Surgeon and Lecturer on Surgery at St. George's Hospital, London.

A SYSTEM OF SURGERY; THEORETICAL AND PRACTICAL.

IN TREATISES BY VARIOUS AUTHORS. AMERICAN EDITION, THOROUGHLY REVISED AND REWRITTEN by JOHN H PACKARD, M.D., Surgeon to the Episcopal and St. Joseph's Hospitals, Philadelphia, assisted by a large corps of the most eminent American surgeons. In three large and very handsome imperial octavo volumes of about 1000 pages each, with over 1000 illustrations on wood and thirteen lithographic plates, beautifully colored. (*Sold only by subscription.*) Price per volume, in cloth, $6 00; in leather, $7 00; in half Russia, $7 50. Per set, in cloth, $18 00; in leather, $21 00; in half Russia, $22 50.

VOLUME I. (*now ready*) contains GENERAL PATHOLOGY, MORBID PROCESSES, INJURIES IN GENERAL, COMPLICATIONS OF INJURIES AND INJURIES OF REGIONS.

VOLUME II. (*nearly ready*) contains DISEASES OF ORGANS OF SPECIAL SENSE, CIRCULATORY SYSTEM, DIGESTIVE TRACT AND GENITO-URINARY ORGANS.

VOLUME III. (*shortly*) contains DISEASES OF THE RESPIRATORY ORGANS, JOINTS, BONES, AND MUSCLES, OPERATIVE AND MINOR SURGERY, GUNSHOT WOUNDS, HOSPITALS AND MISCELLANEOUS SUBJECTS.

This great work, issued some years since in England, has won such universal confidence wherever the language is spoken, that its republication here, in a form more thoroughly adapted to the wants of the American practitioner, has seemed to be a duty owing to the profession.

To accomplish this, the aid has been invited of thirty-three of the most distinguished gentlemen, in every part of the country, and for more than a year they have been assiduously engaged upon the task. Though the original work presents the combined labor of the most eminent members of all the most prominent schools of England, yet the lapse of time since the appearance of the last edition, the progress of science, and the peculiarities of American practice, have rendered necessary a most careful, thorough, and searching revision. Each article has been placed in the hands of a gentleman specially competent to treat its subject, and no labor has been spared to bring each one up to the foremost level of the times, and to adapt it thoroughly to the practice of the country. In certain cases, this has rendered necessary the substitution of an entirely new essay for the original, as in the case of the articles on Skin Diseases, and on Diseases of the Absorbent System, where the views of the authors have been superseded by the advance of medical science, and new articles have therefore been prepared by Drs. ARTHUR VAN HARLINGEN and S. C. BUSEY, respectively. So also in the case of Anæsthetics, in the use of which American practice differs from that of England, the original has been supplemented with a new essay by J. C. REEVE, M.D., treating not only of the employment of ether and chloroform, but of the other anæsthetic agents of more recent discovery. The same careful and conscientious revision has been pursued throughout, leading to an increase of nearly one-fourth in matter, while the series of illustrations has been more than doubled, and the whole is presented as a complete exponent of British and American Surgery, adapted to the daily needs of the working practitioner

In order to bring it within the reach of every member of the profession, the five volumes of the original have been compressed into three, by employing a double-columned imperial octavo page, and in this improved form it is offered at less than one-half the price of the original. It is beautifully printed on handsome laid paper and forms a worthy companion to REYNOLDS'S "SYSTEM OF MEDICINE," which has met with so much favor in every section of the country.

The work will be sold by subscription only, and in due time every member of the profession will be called upon and offered an opportunity to subscribe.

The few notices appended will serve to indicate the hearty approval accorded to the unrevised edition on its appearance some years since:—

There is so much that is instructive, even to the experienced practitioner, in their practical and discriminating manner of dealing with mooted questions, none of which seem to be neglected; their abundant illustrations, drawn at once from an unlimited field of hospital experience, and their candid and sensible mode of handling the whole subject, that these particular portions of the work possess a value which places them far above any publication on the same topics yet issued in the language.—*Am Journ. Med. Sciences.*

The enumeration of the treatises, and the names of the surgical writers from whose pens they proceed, suffice to show that this is no ordinary book, and that in the thousand pages of this goodly volume lies a store of information such as no other surgical work in the language can pretend to offer. Those who are acquainted with the special researches and publications of the respective authors will not fail to notice that by a judicious exercise of editorial discretion, each subject has been entrusted, as far as possible, to a surgeon of the hospitals who is known to have given especial attention to it, and to possess facilities for summing up with authority the accepted opinions of the day, and adding original matter to the stock.—*London Lancet.*

The work must be considered a very complete account of everything connected with the science and practice of surgery. In conclusion we can cordially recommend this work as a valuable addition to the library of the surgeon.—*Edinburgh Medical Journal.*

It is a cyclopædia of surgery of the most complete and extensive character; and we may justly state that its design and execution do great honor to those concerned, and that the large number and high standing of the authors selected for the various monographs render this "System" what it no doubt was intended to be, representative of the actual state of surgical science and art in the country.—*London Lancet.*

In conclusion, we will add that we can most conscientiously recommend the book to every medical practitioner. In recommending the "*System of Surgery*" to our friends who have to deal in surgical cases, we by no means wish to confine our recommendation to them alone. Every practitioner of medicine may cull something worthy of note from a perusal of this volume.—*The British Med. Journal.*

The four volumes remain a monument to the surgical genius of our day. The great majority of metropolitan surgeons of eminence and proved ability are represented in them; and for many years to come, whoever wishes to know the most authoritative words of English Surgical science on most subjects in the domain of surgery, must turn to these pages to read what there is set forth. But taken as a whole it is the most important surgical work which has ever issued from the English press.—*London Lancet.*

BRYANT (THOMAS), F.R.C.S.,
Surgeon to Guy's Hospital.

THE PRACTICE OF SURGERY. Third American, from the Second and Revised English Edition. Thoroughly revised and much improved, by John B. Roberts, M.D. In one large and very handsome imperial octavo volume of over 1000 pages, with 672 illustrations. Cloth, $6 50; leather, $7 50; very handsome half Russia, raised bands, $8 00. (*Just Ready.*)

Mr. Bryant's work has long been a favorite one with surgeons. As its name indicates, it is of a thoroughly practical character. It is distinctly individual in that it gives the results of the author's large and varied experience as an operator and clinical teacher, and is on that account prized deservedly high as an original work. The style is necessarily condensed, the descriptions of surgical diseases brief and to the point. The illustrations are well chosen, and the typical cases of the author's experience are full of interest, and are of more than ordinary value to the working surgeon.—*N. Y. Medical Record*, March 5, 1881.

It is a work especially adapted to the wants of students and practitioners. While not prolix, it affords instruction in sufficient detail for a full understanding of surgical principles and the treatment of surgical diseases. It embraces in its scope all the diseases that are recognized as belonging to surgery, and all traumatic injuries. In discussing these it has seemed to be the aim of the author rather to present the student with practical information, and that alone, than to burden his memory with the views of different writers, however distinguished they might have been. In this edition the whole work has been carefully revised, much of it has been rewritten, important additions have been made to almost every chapter.—*Cincinnati Med. News*, Jan. 1881.

The English edition, from which this is printed, has been carefully revised and rewritten; almost every chapter has received additions, and nearly one hundred new cuts introduced. The labors of the American editor, Dr. John B. Roberts, have very much increased the value of the book. He has introduced many new illustrations and much new material not found in the English edition. He has written too with great conciseness, which is a rare virtue in an American editor of an English work. If one could procure or wished only one surgery, this volume would certainly be selected. If he desired two, Erichsen's Surgery would be added, and if he wished a third, Gross's Surgery would justly be the work selected. As the great work of Gross is amply sufficient for the wants of any surgeon, the priority given to Erichsen, and above all others, to this work of Bryant, is no labored eulogy of the last volume, but a simple and just statement of its demonstrable and pre-eminent merits.—*Am. Med. Bi-Weekly*, Feb. 26, 1881.

ERICHSEN (JOHN E.),
Professor of Surgery in University College, London, etc.

THE SCIENCE AND ART OF SURGERY; being a Treatise on Surgical Injuries, Diseases and Operations. Carefully revised by the Author from the Seventh and enlarged English Edition. Illustrated by eight hundred and sixty two engravings on wood. In two large and beautiful octavo volumes of nearly 2000 pages: cloth, $8 50; leather, $10 50; half Russia, $11 50. (*Now Ready.*)

Of the many treatises on Surgery which it has been our task to study, or our pleasure to read, there is none which in all points has satisfied us so well as the classic treatise of Erichsen. His polished, clear style, his freedom from prejudice and hobbies, his unsurpassed grasp of his subject, and vast clinical experience, qualify him admirably to write a model text-book. When we wish, at the least cost of time, to learn the most of a topic in surgery, we turn, by preference, to his work. It is a pleasure, therefore, to see that the appreciation of it is general, and has led to the appearance of another edition.—*Med. and Surg. Reporter*, Feb. 2, 1878.

Notwithstanding the increase in size, we observe that much old matter has been omitted. The entire work has been thoroughly written up, and not merely amended by a few extra chapters. A great improvement has been made in the illustrations. One hundred and fifty new ones have been added, and many of the old ones have been redrawn. The author highly appreciates the favor with which his work has been received by American surgeons, and has endeavored to render his latest edition more than ever worthy of their approval. That he has succeeded admirably, must, we think, be the general opinion. We heartily recommend the book to both student and practitioner.—*N. Y. Med. Journal*, Feb. 1878.

The seventh edition is before the world as the last word of surgical science. There may be monographs which excel it upon certain points, but as a conspectus upon surgical principles and practice it is unrivalled. It will well reward practitioners to read it, for it has been a peculiar province of Mr. Erichsen to demonstrate the absolute interdependence of medical and surgical science. We need scarcely add, in conclusion, that we heartily commend the work to students that they may be grounded in a sound faith, and to practitioners as an invaluable guide at the bedside.—*Am. Practitioner*, April, 1878.

For the past twenty years Erichsen's Surgery has maintained its place as the leading text-book, not only in this country, but in Great Britain. That it is able to hold its ground, is abundantly proven by the thoroughness with which the present edition has been revised, and by the large amount of valuable material that has been added. Aside from this, one hundred and fifty new illustrations have been inserted, including quite a number of microscopical appearances of pathological processes. So marked is this change for the better, that the work almost appears as an entirely new one.—*Med. Record*, Feb. 23, 1878.

HOLMES (TIMOTHY), M.D.,
Surgeon to St. George's Hospital, London.

SURGERY, ITS PRINCIPLES AND PRACTICE. In one handsome octavo volume of nearly 1000 pages, with 411 illustrations. Cloth, $6; leather, $7; half Russia, $7 50.

This is a work which has been looked for on both sides of the Atlantic with much interest. Mr. Holmes is a surgeon of large and varied experience, and one of the best known, and perhaps the most brilliant writer upon surgical subjects in England. It is a book for students—and an admirable one—and for the busy general practitioner. It will give a student all the knowledge needed to pass a rigid examination. The book fairly justifies the high expectations that were formed of it. Its style is clear and forcible, even brilliant at times, and the conciseness needed to bring it within its proper limits has not impaired its force and distinctness.—*N. Y. Med. Record*, April 14, 1876.

It will be found a most excellent epitome of surgery by the general practitioner who has not the time to give attention to more minute and extended works, and to the medical student. In fact, we know of no one we can more cordially recommend. The author has succeeded well in giving a plain and practical account of each surgical injury and disease, and of the treatment which is most commonly advisable. It will no doubt become a popular work in the profession, and especially as a text-book.—*Cincinnati Med. News*, April, 1876.

WELLS (*J. SOELBERG*),

Professor of Ophthalmology in King's College Hospital, &c.

A TREATISE ON DISEASES OF THE EYE. Third American, from the Third London Edition. Thoroughly revised, with copious additions, by Chas. S. Bull, M.D., Surgeon and Pathologist to the New York Eye and Ear Infirmary. Illustrated with about 250 engravings on wood, and six colored plates. Together with selections from the Test-types of Jaeger and Snellen. In one large and very handsome octavo volume of 900 pages. Cloth, $5; leather, $6; half Russia, raised bands, $6 50. (*Just Ready.*)

The long-continued illness of the author, with its fatal termination, has kept this work for some time out of print, and has deprived it of the advantage of the revision which he sought to give it during the last years of his life. This edition has therefore been placed under the editorial supervision of Dr. Bull, who has labored earnestly to introduce in it all the advances which observation and experience have acquired for the theory and practice of ophthalmology since the appearance of the last revision. To accomplish this, considerable additions have been required, and the work is now presented in the confidence that it will fully deserve a continuance of the very marked favor with which it has hitherto been greeted as a complete, but concise, exposition of the principles and facts of its important department of medical science.

The additions made in the previous American editions by Dr. Hays have been retained, including the very full series of illustrations and the test-types of Jaeger and Snellen.

This new edition of Dr. Wells's great work on the eye will be welcomed by the profession at large as well as by the oculist. It contains much new matter relating to treatment and pathology, and is brought thoroughly up with the present status of ophthalmology. Its chapter on refraction and accommodation—a subject much discussed of late years, and of great importance—is exceedingly complete.—*Louisville Med. News*, Nov. 13, 1880.

The merits of Wells's treatise on diseases of the eye have been so universally acknowledged, and are so familiar to all who profess to have given any attention to ophthalmic surgery, that any discussion of them at this late day will be a work of supererogation. Very little that is practically useful in recent ophthalmic literature has escaped the editor, and the third American edition is well up to the times. As a text-book on ophthalmic surgery for the English-speaking practitioner, it is without a rival.—*Am. Journ. of Med. Sci.*, Jan. 1881.

The work has justly held a high place in English ophthalmic literature, and at the time of its first appearance was the best treatise of its kind in the language. In the second edition, the author showed industrious research in adding new material from every quarter, and his spirit was eminently candid. A work thus built up by honest effort should not be suffered to die, and we are pleased to receive this third edition from the hands of Dr. Bull. His labor has been arduous, as the very great number of additions bracketed with his initial testify. Under the editorship which the third edition has enjoyed, the work is sure to sustain its good reputation, and to maintain its usefulness.—*N. Y. Med. Journ.*, Jan. 1881.

There is really no work which approaches it in adaptation to the wants of the general practitioner, while the most advanced specialist cannot rise from a perusal of its ample pages without having added to his knowledge. The American editor, Dr. Bull, won his spurs in ophthalmology some time back. His additions to the work of the lamented Wells are many, judicious, and timely, and in just so much have added to its value.—*Am. Practitioner*, Jan. 1881.

NETTLESHIP (*EDWARD*), *F.R.C.S.*,

Ophthalmic Surg. and Lect. on Ophth. Surg. at St. Thomas' Hospital, London.

MANUAL OF OPHTHALMIC MEDICINE. In one royal 12mo. volume of over 350 pages, with 89 illustrations. Cloth, $2. (*Just Ready.*)

The author is to be congratulated upon the very successful manner in which he has accomplished his task; he has succeeded in being concise without sacrificing clearness, and, including the whole ground covered by more voluminous text-books, has given an excellent *résumé* of all the practical information they contain. We do not hesitate to pronounce Mr. Nettleship's book the best manual on ophthalmic surgery for the use of students and "busy practitioners" with which we are acquainted.—*Am. Jour. Med. Sciences*, April, 1880.

CARTER (*R. BRUDENELL*), *F.R.C.S.*,

Ophthalmic Surgeon to St. George's Hospital, etc.

A PRACTICAL TREATISE ON DISEASES OF THE EYE. Edited, with test-types and Additions, by JOHN GREEN, M.D. (of St. Louis, Mo.). In one handsome octavo volume of about 500 pages, and 124 illustrations. Cloth, $3 75.

It is with great pleasure that we can endorse the work as a most valuable contribution to practical ophthalmology. Mr. Carter never deviates from the end he has in view, and presents the subject in a clear and concise manner, easy of comprehension, and hence the more valuable. We would especially commend, however, as worthy of high praise, the manner in which the therapeutics of disease of the eye is elaborated, for here the author is particularly clear and practical, where other writers are unfortunately too often deficient. The final chapter is devoted to a discussion of the uses and selection of spectacles, and is admirably compact, plain, and useful, especially the paragraphs on the treatment of presbyopia and myopia. In conclusion, our thanks are due the author for many useful hints in the great subject of ophthalmic surgery and therapeutics, a field where of late years we glean but a few grains of sound wheat from a mass of chaff.—*New York Medical Record*, Oct. 23, 1875.

BROWNE (*EDGAR A.*),

Surgeon to the Liverpool Eye and Ear Infirmary, and to the Dispensary for Skin Diseases.

HOW TO USE THE OPHTHALMOSCOPE. Being Elementary Instructions in Ophthalmoscopy, arranged for the Use of Students. With thirty-five illustrations. In one small volume royal 12mo. of 120 pages: cloth, $1.

LAURENCE'S HANDY-BOOK OF OPHTHALMIC SURGERY, for the use of Practitioners. Second edition, revised and enlarged. With numerous illustrations. In one very handsome octavo volume, cloth, $2 75.

LAWSON'S INJURIES TO THE EYE, ORBIT AND EYELIDS: their Immediate and Remote Effects. With about one hundred illustrations. In one very handsome octave volume, cloth, $3 50.

BURNETT (CHARLES H.), M.A., M.D.,

Aural Surg. to the Presb. Hosp., Surgeon-in-charge of the Infir. for Dis. of the Ear, Phila.

THE EAR, ITS ANATOMY, PHYSIOLOGY AND DISEASES.

A Practical Treatise for the Use of Medical Students and Practitioners. In one handsome octavo volume of 615 pages, with eighty-seven illustrations: cloth, $4 50; leather, $5 50; half Russia, $6 00. (*Lately Issued.*)

Foremost among the numerous recent contributions to aural literature will be ranked this work of Dr. Burnett. It is impossible to do justice to this volume of over 600 pages in a necessarily brief notice. It must suffice to add that the book is profusely and accurately illustrated, the references are conscientiously acknowledged, while the result has been to produce a treatise which will henceforth rank with the classic writings of Wilde and Von Tröltsch.—*The Lond. Practitioner*, May, 1879.

On account of the great advances which have been made of late years in otology, and of the increased interest manifested in it, the medical profession will welcome this new work, which presents clearly and concisely its present aspect, whilst clearly indicating the direction in which further researches can be most profitably carried on. Dr. Burnett from his own matured experience, and availing himself of the observations and discoveries of others, has produced a work which, as a text-book, stands *facile princeps* in our language. We had marked several passages as well worthy of quotation and the attention of the general practitioner, but their number and the space at our command forbid. Perhaps it is better, as the book ought to be in the hands of every medical student, and its study will well repay the busy practitioner in the pleasure he will derive from the agreeable style in which many otherwise dry and mostly unknown subjects are treated. To the specialist the work is of the highest value, and his sense of gratitude to Dr. Burnett will, we hope, be proportionate to the amount of benefit he can obtain from the careful study of the book, and a constant reference to its trustworthy pages.—*Edinburgh Med. Jour.*, Aug. 1878.

TAYLOR (ALFRED S.), M.D.,

Lecturer on Med. Jurisp. and Chemistry in Guy's Hospital.

A MANUAL OF MEDICAL JURISPRUDENCE. Eighth American edition.

Thoroughly revised and rewritten. Edited by JOHN J. REESE, M.D., Prof. of Med. Jurisp. and Toxicology in the Univ. of Penn. In one large octavo volume of 933 pages, with 70 illustrations. Cloth, $5; leather, $6; half Russia, raised bands, $6 50. (*Just Ready.*)

The American editions of this standard manual have for a long time laid claim to the attention of the profession in this country; and that the profession has recognized this claim with favor is proven by the call for frequent new editions of the work. This one, the eighth, comes before us as embodying the latest thoughts and emendations of Dr. Taylor, upon the subject to which he devoted his life, with an assiduity and success which made him *facile princeps* among English writers on medical jurisprudence. Both the author and the book have made a mark too deep to be affected by criticism, whether it be censure or praise. In this case, however, we should only have to seek for laudatory terms.—*Am. Journ. of Med. Sci.*, Jan. 1881.

It is not very often that a medical book reaches its tenth edition, or that the last earthly labor is performed by the author in retouching the work that first came from his hand thirty-five years before. All this, however, has happened in the case of Dr. Taylor and his classical treatise. The pen dropped from the grasp only when the shadows of old age were rapidly deepening into the darkness of death. Under the circumstances, all the journalist has to do is to announce, not criticize, the completed task. The value of the gem is too well known to require more than the telling that the master-hand has rebrightened its facets and polished its angles before leaving it as his legacy to his brethren in the profession.—*Phila Med. Times*, Dec. 4, 1880.

It will suffice to remark that this new edition shows the signs of judicious revision. A great number of illustrative medico-legal cases which have occurred since the last edition was published are cited in their proper connection, and add much to the interest and value of the work; they comprise the bulk of the additions to the text. As an indication of the freshness of the work, we notice numerous references to medico-legal experience that has transpired during the year just ended; among these is a comment by the American editor upon that midsummer madness, the Tanner fasting exploit of last August. In these features and in others there is ample evidence that this admirable book will maintain its high place as a standard authority concerning the matters of which it treats.—*Boston Med. and Surg. Journal*, Jan. 13, 1881.

BY THE SAME AUTHOR.

THE PRINCIPLES AND PRACTICE OF MEDICAL JURISPRUDENCE.

Second Edition, Revised, with numerous Illustrations. In two large octavo volumes, cloth, $10 00; leather, $12 00.

This great work is now recognized in England as the fullest and most authoritative treatise on every department of its important subject. In laying it, in its improved form, before the American profession, the publishers trust that it will assume the same position in this country.

BY THE SAME AUTHOR.

POISONS IN RELATION TO MEDICAL JURISPRUDENCE AND MEDICINE.

Third American, from the Third and Revised English Edition. In one large octavo volume of 850 pages; cloth, $5 50; leather, $6 50.

The present is based upon the two previous editions; "but the complete revision rendered necessary by time has converted it into a new work." This statement from the preface contains all that it is desired to know in reference to the new edition. The works of this author are already in the library of every physician who is liable to be called upon for medico-legal testimony (and what one is not?), so that all that is required to be known about the present book is that the author has kept it abreast with the times. What makes it now, as always, especially valuable to the practitioner is its conciseness and practical character, only those poisonous substances being described which give rise to legal investigations.—*The Clinic*, Nov. 6, 1875.

Dr. Taylor has brought to bear on the compilation of this volume, stores of learning, experience, and practical acquaintance with his subject, probably far beyond what any other living authority on toxicology could have amassed or utilised. He has fully sustained his reputation by the consummate skill and legal acumen he has displayed in the arrangement of the subject-matter, and the result is a work on Poisons which will be indispensable to every student or practitioner in law and medicine.—*The Dublin Journ. of Med. Sci.*, Oct. 1875.

ROBERTS (*WILLIAM*), *M.D.*,
Lecturer on Medicine in the Manchester School of Medicine, &c.

A PRACTICAL TREATISE ON URINARY AND RENAL DISEASES, including Urinary Deposits. Illustrated by numerous cases and engravings. Third American, from the Third Revised and Enlarged London Edition. In one large and handsome octavo volume of over 600 pages. Cloth, $4. (*Just Ready.*)

THOMPSON (*SIR HENRY*),
Surgeon and Professor of Clinical Surgery to University College Hospital.

LECTURES ON DISEASES OF THE URINARY ORGANS. With illustrations on wood. Second American from the Third English Edition. In one neat octavo volume. Cloth, $2 25.

BY THE SAME AUTHOR.

ON THE PATHOLOGY AND TREATMENT OF STRICTURE OF THE URETHRA AND URINARY FISTULÆ. With plates and wood-cuts. From the third and revised English edition. In one very handsome octavo volume, cloth, $3 50.

TUKE (*DANIEL HACK*), *M.D.*,
Joint author of The Manual of Psychological Medicine, &c.

ILLUSTRATIONS OF THE INFLUENCE OF THE MIND UPON THE BODY IN HEALTH AND DISEASE. Designed to illustrate the Action of the Imagination. In one handsome octavo volume of 416 pages, cloth, $3 25.

BLANDFORD (*G. FIELDING*), *M.D., F.R.C.P.*,
Lecturer on Psychological Medicine at the School of St. George's Hospital, &c.

INSANITY AND ITS TREATMENT: Lectures on the Treatment, Medical and Legal, of Insane Patients. With a Summary of the Laws in force in the United States on the Confinement of the Insane. By ISAAC RAY, M. D. In one very handsome octavo volume of 471 pages; cloth, $3 25.

It satisfies a want which must have been sorely felt by the busy general practitioners of this country. It takes the form of a manual of clinical description of the various forms of insanity, with a description of the mode of examining persons suspected of insanity. We call particular attention to this feature of the book, as giving it a unique value to the general practitioner. If we pass from theoretical considerations to descriptions of the varieties of insanity as actually seen in practice and the appropriate treatment for them, we find in Dr. Blandford's work a considerable advance over previous writings on the subject. His pictures of the various forms of mental disease are so clear and good that no reader can fail to be struck with their superiority to those given in ordinary manuals in the English language or (so far as our own reading extends) in any other.—*London Practitioner*, Feb. 1871.

LEA (*HENRY C.*).

SUPERSTITION AND FORCE: ESSAYS ON THE WAGER OF LAW, THE WAGER OF BATTLE, THE ORDEAL AND TORTURE. Third Revised and Enlarged Edition. In one handsome royal 12mo. volume of 552 pages. Cloth, $2 50. (*Just Ready.*)

This valuable work is in reality a history of civilization as interpreted by the progress of jurisprudence. . . . In "Superstition and Force" we have a philosophic survey of the long period intervening between primitive barbarity and civilized enlightenment. There is not a chapter in the work that should not be most carefully studied, and however well versed the reader may be in the science of jurisprudence, he will find much in Mr. Lea's volume of which he was previously ignorant. The book is a valuable addition to the literature of social science.—*Westminster Review*, Jan. 1880.

The appearance of a new edition of Mr. Henry C. Lea's "Superstition and Force" is a sign that our highest scholarship is not without honor in its native country. Mr. Lea has met every fresh demand for his work with a careful revision of it, and the present edition is not only fuller and, if possible, more accurate than either of the preceding, but, from the thorough elaboration, is more like a harmonious concert and less like a batch of studies.—*The Nation*, Aug. 1, 1878.

Many will be tempted to say that this, like the "Decline and Fall," is one of the uncriticizable books. Its facts are innumerable, its deductions simple and inevitable, and its *chevaux-de-frise* of references bristling and dense enough to make the keenest, stoutest, and best equipped assailant think twice before advancing. Nor is there anything controversial in it to provoke assault. The author is no polemic. Though he obviously feels and thinks strongly, he succeeds in attaining impartiality. Whether looked on as a picture or a mirror, a work such as this has a lasting value.—*Lippincott's Magazine*, Oct. 1878.

BY THE SAME AUTHOR.

STUDIES IN CHURCH HISTORY. THE RISE OF THE TEMPORAL POWER—BENEFIT OF CLERGY—EXCOMMUNICATION. In one large royal 12mo. volume of 516 pp.; cloth, $2 75. (*Lately Published.*)

The story was never told more calmly or with greater learning or wiser thought. We doubt, indeed, if any other study of this field can be compared with this for clearness, accuracy, and power.—*Chicago Examiner*, Dec. 1870.

Mr. Lea's latest work, "Studies in Church History," fully sustains the promise of the first. It deals with three subjects—the Temporal Power, Benefit of Clergy, and Excommunication, the record of which has a peculiar importance for the English student, and is a chapter on Ancient Law likely to be regarded as final. We can hardly pass from our mention of such works as these—with which that on "Sacerdotal Celibacy" should be included—without noting the literary phenomenon that the head of one of the first American houses is also the writer of some of its most original books.—*London Athenæum*, Jan. 7, 1871.

NEW MEDICAL BOOKS.

KEATING ON INFANCY—Just Ready.

THE MOTHER'S GUIDE IN THE MANAGEMENT AND FEEDING OF INFANTS. By JOHN M. KEATING, M.D., Lecturer on the Diseases of Children in the Univ. of Penna., etc. In one handsome 12mo. volume of 118 pages. Cloth, $1 00.

The title of this little book is well chosen, and Dr. Keating has written a work which should be read, and its precepts followed by every intelligent mother in this country. It is free from all technical terms, the language is clear and distinct, and so carefully written that it cannot fail to become popular. It has always been a mooted question how far it is well to instruct the public, but works like this one will aid the physician immensely, for it saves the time he is constantly giving his patients in instructing them on the subjects here dwelt so thoroughly and practically upon. Dr Keating has written a practical book, has carefully avoided unnecessary repetition, and, I think, successfully instructed the mother in the details of the treatment of her child as devolve upon her; he has studiously omitted giving prescriptions, and instructs the mother when to call upon the doctor, as his duties are totally distinct from hers.—*Am. Journ. of Obstetrics*, Oct. 1881.

HOLDEN'S LANDMARKS—New Edition—Just Ready.

LANDMARKS, MEDICAL AND SURGICAL. By LUTHER HOLDEN, F.R.C.S., Surgeon to St. Bartholomew's and the Foundling Hospitals. Second American, from the third English Edition, with additions by W. W. KEEN, M.D., Prof. of Artistic Anatomy in the Penna. Acad. of the Fine Arts; formerly Lecturer on Anatomy in the Phila. School of Anatomy, etc. In one handsome royal 12mo. volume of about 140 pages. Cloth, $1.

The additions made by Dr Keen are to be found on every page. They are always judicious, and leave one with the impression that the English edition must have been quite incomplete on many practical points.—*Louisville Med. News*, Oct. 8, 1881.

BARTHOLOW'S MEDICAL ELECTRICITY—Just Ready.

A PRACTICAL TREATISE ON ELECTRICITY IN ITS APPLICATIONS TO MEDICINE. By ROBERTS BARTHOLOW, A.M., M.D., LL.D., Professor of Materia Medica and General Therapeutics in the Jefferson Medical College of Philadelphia. In one very handsome octavo volume of 262 pages, with 92 illustrations. Cloth, $2 50.

It is a practical treatise by a practical writer for practical men. We most cordially recommend it to all who feel an interest in the subject, and this surely includes all intelligent physicians, for none can afford to disregard a remedy of its indisputable value in a large class of troublesome, and some otherwise incurable, affections.—*Atlanta Med. Register*, Oct. 1881.

GROSS ON DISORDERS OF THE MALE SEXUAL ORGANS—Just Ready.

A PRACTICAL TREATISE ON IMPOTENCE, STERILITY, AND ALLIED DISORDERS OF THE MALE SEXUAL ORGANS. By SAMUEL W. GROSS, A.M., M.D., Lecturer on Genito-Urinary and Venereal Diseases in the Jefferson Medical College, Philada. In one very handsome octavo volume of 174 pages, with 16 illustrations. Cloth, $1 50.

The author has devoted much time to the hardest study of this most trying class of diseases, and this labor, together with the fruit of laborious research into the scattered literature of the subject, constitutes the result of his investigations. We can earnestly commend it to the practitioner as the very best work upon the subject in the English language.—*Nashville Journ. of Med. and Surg.*, Oct. 1881.

MITCHELL ON DISEASES OF THE NERVOUS SYSTEM—Just Ready.

LECTURES ON DISEASES OF THE NERVOUS SYSTEM, ESPECIALLY IN WOMEN. By S. WEIR MITCHELL, M.D., Physician to the Orthopædic Hospital and Infirmary for Diseases of the Nervous System. In one very handsome 12mo. volume of about 250 pages, with five lithographic plates. Extra cloth, $1 75.

The cultivated, colloquial style assumed by the author, becomes the vehicle of a work of thought and expression peculiarly felicitous. Nor is the impression wanting that nowhere does the locutor appear to better advantage than in those strong points upon which he has bestowed so much attention and care. In fine, we would not withhold from this charming little work its due meed of praise, regarding it as very clever—its cleverness, in many places, mingled with wisdom, as offering food for thought, and as being remunerative for its perusal. —*Am. Journ. of Med. Sciences*, July, 1881.

CLOWES' CHEMISTRY—New Edition—Just Ready.

AN ELEMENTARY TREATISE ON PRACTICAL CHEMISTRY AND QUALITATIVE INORGANIC ANALYSIS By FRANK CLOWES, D.Sc. London, Senior Science Master at the High School, Newcastle-under-Lyme. Specially adapted for use in the Laboratories of Schools and Colleges, and by Beginners. Second American, from the Third and revised English edition, with about 50 illustrations on wood. In one very handsome royal 12mo. volume of 372 pages. Cloth, $2 50.

The book is eminently a practical one, and we can cordially recommend it as one of the best text-books for practical instruction in the laboratory. The analytical reactions and methods are those which experience has proved to be the most accurate, and the directions for working are given so fully as to be perfectly intelligible to the student without extended verbal explanation from the instructor.—*Boston Med. and Surg. Journ.*, March, 1881.

THOMAS ON WOMEN—New and Revised Edition—Now Ready.

A PRACTICAL TREATISE ON THE DISEASES OF WOMEN. By T. GAILLARD THOMAS, M.D., Prof. of Obstetrics, etc., in the College of Physicians and Surgeons, New York. Fifth edition, thoroughly revised and rewritten. In one large and handsome octavo volume of 810 pages, with 266 illustrations. Cloth, $5; leather, $6; very handsome half Russia, raised bands, $6 50.

HENRY C. LEA'S SON & CO., Philadelphia.

PROSPECTUS FOR 1881.

THE AMERICAN JOURNAL OF THE MEDICAL SCIENCES.

In commencing its sixty-first year, the publishers of the "AMERICAN JOURNAL OF THE MEDICAL SCIENCES" have much pleasure in assuring its wide circle of readers that at no period has it had the prospect of a more extended field of usefulness.

For 1881 the "American Journal" has the promise of its usual variety of important contributions from distinguished members of the profession in all parts of the country. Special attention will be bestowed, as heretofore, on its Bibliographical Department and Quarterly Summaries to keep its subscribers informed as to all subjects of professional interest from every quarter.

With its attendant periodical, "THE MEDICAL NEWS AND ABSTRACT," it combines the advantages of the elaborate preparation which can be given to a quarterly, and the prompt conveyance of intelligence by the monthly, while, the whole being under a single editorial supervision, the subscriber is secured against the duplication of matter inevitable under other circumstances. These efforts the publishers seek to second by offering these periodicals at a price unprecedentedly low—a price which places them within the reach of every practitioner, and gives the equivalent of three large octavo volumes for the comparatively trifling cost of FIVE DOLLARS *per annum*.

The "NEWS AND ABSTRACT" consists of sixty-four pages monthly, in a neat cover. It contains a CLINICAL DEPARTMENT in which will be continued the series "ORIGINAL AMERICAN CLINICAL LECTURES, contributed by gentlemen of the highest reputation throughout the United States, together with a choice selection of Foreign Lectures and Hospital Notes and Gleanings. Then follows the "MONTHLY ABSTRACT," systematically arranged and classified, and presenting five or six hundred articles yearly; each number concluding with an EDITORIAL and a NEWS DEPARTMENT, giving current professional intelligence, domestic and foreign, the whole fully indexed at the close of each volume, rendering it of permanent value for reference.

The subscription price to the "NEWS AND ABSTRACT" will be Two Dollars and Half per annum, invariably in advance, at which rate it will rank as one of the cheapest medical periodicals in the country. But it will also be furnished, free of all charge, in commutation with the "AMERICAN JOURNAL OF THE MEDICAL SCIENCES," to all who remit FIVE DOLLARS in advance, thus giving to the subscriber, for that very moderate sum, a complete record of medical progress throughout the world, in the compass of about two thousand large octavo pages.

These terms may be recapitulated as follows:—

TERMS FOR 1881.

The AMERICAN JOURNAL OF THE MEDICAL SCIENCES, published quarterly (1150 pages per annum), and
The MEDICAL NEWS AND ABSTRACT, published monthly (768 pages per annum), } Five Dollars per annum, in advance.

SEPARATE SUBSCRIPTIONS TO

The AMERICAN JOURNAL OF THE MEDICAL SCIENCES, when not paid for in advance, } Five Dollars.
The MEDICAL NEWS AND ABSTRACT, invariably in advance, Two Dollars and a Half.

*** Advance-paying subscribers can obtain, at the close of the year, cloth covers, gilt lettered, for binding the volumes of the JOURNAL (two annually) and the NEWS AND ABSTRACT (one annually), free by mail, on remitting ten cents for each cover.

The safest mode of remittance is by bank check or draft, or postal money order drawn to the order of the undersigned. Where these are not accessible, remittances for the "JOURNAL" and "NEWS AND ABSTRACT" may be made at the risk of the publishers by forwarding in REGISTERED letters. Address

THE MEDICAL NEWS.

A National Weekly Medical Periodical, each Number containing from 28 to 32 Double-Column Quarto Pages exclusive of Advertisements.

In these days of rapid thought and quick transmission of intelligence, the profession demand to be supplied with information at more frequent intervals than formerly. In meeting this demand, by converting the "*Medical News and Abstract*" from a monthly to a weekly, the publishers, however, by no means propose to confine themselves to the beaten track, and simply to present another medical weekly of the ordinary character and without distinguishing features. They are convinced that the profession desires to have and will liberally support the best, and the best is only to be obtained by securing the collaboration not of a few men only, or of the men of a single locality, but by uniting the efforts of the ablest minds of the profession throughout the whole continent. The distinguishing characteristic of the "Weekly News" will, therefore, be that it will be the mouthpiece or organ not of a single clique or school or city, but of the profession at large, and the promises already received are sufficient to show that with unexampled unanimity the leaders of medical thought everywhere endorse the project, and pledge their aid to its success. In addition to this the services of a numerous and able editorial corps have been secured, whose care it will be that every department of medical science shall receive due attention and be thoroughly represented in its pages. A periodical so conducted, essentially practical in its character, with the broad and comprehensive scope designed for the "News," becomes a necessity for every practitioner. It is the intention of all concerned that it shall be so, and, therefore, anticipating a circulation unparalleled in medical journalism, an amount of matter will be given in each number which will render it, at the very moderate subscription price of Five Dollars per annum, the cheapest periodical presented to the profession in any country.

Each number will contain from 28 to 32 large quarto double-column pages of reading matter (exclusive of advertisements), beautifully printed on fine toned paper, from an exceedingly clear type cast expressly for this purpose. Space will thus be afforded for an immense variety of intelligence, which will be distributed under the following headings:—

Original Lectures, contributed by the most prominent and ablest teachers of the day, will occupy the opening pages. These lectures will be inserted under special arrangement with their authors, and will be invariably revised by them before publication, thus enjoying an accuracy and authenticity impossible to attain by any other method.

This will be followed by a department of Original Articles, which will be of a brief and practical nature (the pages of the "*American Journal of the Medical Sciences*" being reserved for articles of a more elaborate character), emanating from the best professional minds of the country, and the same high standard will be observed in their selection which has secured for the "*American Journal*," during the sixty-one years of its uninterrupted publication, the enviable position it occupies in the medical literature of the world, and which has caused it to be regarded with just pride during this long period by both the profession and its collaborators.

Hospital Notes will be a feature of the "*Medical News*." It is intended in this department to utilize, for the benefit of the whole profession, the vast and rich stores of clinical experience which accumulate in the hospitals of our country, and which heretofore, to a large extent, have been lost to the general medical public. In addition to the record of interesting and instructive cases, it is intended to publish from time to time articles showing the local methods and peculiarities of treatment which are practised in the various cities of the Union.

The "Progress of Medical Science" will next follow. In this department will be presented, in a condensed form, the advances made in the various branches of medicine and the collateral sciences. For this purpose the columns of all professional periodicals of im-

Clinical Lectures.

ON SOME CATARRHAL AND MUSCULAR DISORDERS OF THE STOMACH.

A CLINICAL LECTURE.

BY MORRIS LONGSTRETH, M.D.,

ONE OF THE ATTENDING PHYSICIANS TO THE PENNSYLVANIA HOSPITAL.

GENTLEMEN: In bringing this subject before you it is not so much my purpose to advance any new views of the pathology and treatment of the much-abused organ, the stomach, as it is to give a view of the subject from new aspects. I wish to bring prominently before you certain considerations of the causes and changes in stomach troubles and their requirements for treatment, which, while well known, have been too much put aside and forgotten. While the causes of which we will speak are not the only ones, they are, I think, very much more frequently the source of trouble than is usually acknowledged. These pathological alterations also, while generally spoken of as functional in character, and which exhibit such wide variations of functional disturbance, are yet always of essentially the same type, though exhibiting so widely different grades that their relationship is sometimes with difficulty recognizable, or is even wholly denied.

Let us first arrive at the proper basis for appreciating the points here alluded to, in brief point out the anatomical structure of this organ and the particular relation which its various parts have to its functional activity, both while at work and during periods of rest. The stomach has three coats; the inner or mucous coat is an arrangement of epithelial cells resting on a basement membrane covering the submucous connective tissue. Numerous gland-tubes are everywhere found, whose office is to secrete the digestive fluid. The submucous connective tissue is a most important part of this coat, and changes in its condition, as we shall see later, bring about most harmful effects on the epithelium and the secreting glands. The next coat is composed of muscular tissue, the bands of which are divided off into compartments, as it were, by more or less broad septa of connective or fibrous tissue. This coat is, I believe, of first-rate importance in the digestive function, much more so than it usually receives credit, and to it I wish especially to call your attention. I believe that in many forms of indigestion it becomes very markedly changed. Let us remember that the bloodvessels which furnish the nutriment for the functional activity of

the inner or mucous membrane coat, traverse this layer and the submucous tissue to reach their point of distribution. The peritoneal coat forms the covering of the stomach, but its anatomy and anatomical alterations, though important for certain other stomach diseases, are not of much concern to us in dealing with our present subject.

Let me insist again that the stomach is a mucous membrane organ, specialized, however, as is the rest of the digestive tract, by two factors dependent on its anatomical structure: first, the occurrence of glands supplying the digestive fluid; and second, an abundant and moderately powerful muscular structure in its walls, which is potent in the performance of digestion.

Having, therefore, gentlemen, to deal with a mucous membrane, let us see what forms of disease we should expect, from our knowledge of its structure and functions, to occur as results of deleterious causes acting on it, either from without or within. It is important, also, to call to mind the group of causes which we know are capable of affecting its action. And not the least important of the facts to be remembered are the anatomical and functional relations which this viscus holds to neighbouring organs. In speaking of the anatomical structure of the stomach no allusion was made to its nervous and vascular supplies, or to the arrangement of its lymphatics—all very important factors in its diseased conditions.

Starting, then, with the fact of a mucous membrane, the most important change that can come to it, excluding, of course, morbid new formation and traumatism, is in the amount of mucus which it secretes, whether this is an abatement or an increase from the normal. And with this fluctuation, of course go hand in hand alterations in the amount of the peculiar digestive juices which it is the special function of the stomach to supply.

We know of no morbid influence, and I do not think one can be conceived of, which, acting on a normal stomach, does not at once primarily change the amount of mucus which it secretes. Whether such influences propagate their effects through the nervous system, come from cold, in the sense of catching cold, or through changes in correlated organs, the effects are primarily evidenced by a changed blood supply, and a variation in the amount of this nutritive fluid condition a departure from the normal secretion, both in amount and in quality.

The type of stomach disease is, therefore, of a catarrhal character, and the chief phenomenon of the morbid process, whether we speak of it as inflammation, or a catarrh, or simply a mucous condition, is an alteration of the mucous secretion.

I show you here a man æt. 28, a weaver. The history he gave was that, five months ago, his stomach began feeling badly shortly after each meal, and continuing for some hours after. This feeling of discomfort, and it amounted on some occasions to pain, kept increasing in severity, and seven weeks ago another marked symptom was added, viz., vomiting. The contents of the stomach were rejected about half an hour after eating. He could give no particular account of the appearance of this material, further than that it seemed to be "just the food." About a week ago he was compelled from weakness to stop work. Two days ago, and again yesterday, he says he vomited a good deal of blood, of a fresh character and clotted, and after this felt very weak but not faint.

The amount of food taken during all this time was progressively lessened, and had been previously, and since the commencement of the symptoms, of a coarse character—the rough, ill-prepared food of a common workman boarding house.

Upon examination the man was seen to be pale, not strikingly, if at all, emaciated, but he was very far from showing the rounded fulness of a man of health. He complained of, not headache, as he says, but of a boring feeling through the front part of the head from temple to temple, and through the forehead above the root of the nose. His lips and gums are of a pale pink; the tongue is coated with a thin whitish layer, especially at the back and along the middle portion, reaching about two-thirds to the tip; the sides of the tongue are pale, much paler than other parts of the mucous membrane of the mouth; but mark well, gentlemen, the borders of the tongue, for you will see here something which I believe is of great importance as a sign of the condition of this patient's stomach, as well as perhaps of the intestinal mucous membrane. What do we see? The markings of the teeth. These fluted depressions correspond to the body of the tooth, and the prominent portions to the interstices between the teeth. We see that the intervals between the teeth are, in his case, considerable, and here where he has lost a tooth, we find no fluted depression but a larger projection of the tongue fitting into the interval. We note, too, that his teeth are in good condition.

He complains not of a bad taste in his mouth; though he says he has had a bitter taste at times, especially on waking in the morning; it is now rather a want of taste, and a feeling of cotton-wool or spider webs filling the mouth and fauces. Latterly his food has had no particular taste, and did not excite any relish.

The tendency to vomit since the blood appeared last on yesterday has lessened, but since then he has taken almost nothing, and that of a fluid nature and in very small quantities. However, there has been some nausea, and a little mucus was ejected.

The examination of the abdomen shows no distension, in fact you see it rather flat, and the feeling of it is that of moderate firmness. Percussion gives no especial evidence. You see that this examination has given him no great pain or distress. Let us examine the region of the stomach more particularly. Carefully with the finger tips I pass over the whole upper part of the abdomen. There is no greater sense of resistance or firmness than at other parts of the abdomen, and no especially painful spot to be detected; in fact while the epigastric region is the part where he has had the feeling of discomfort in the past, it has not been confined to this part, and there has been a lesser degree of it at times over other portions. So it is with the sensation I am now giving him, he feels it most over the region from the umbilicus to the epigastrium and to the borders of the ribs, but there is also discomfort from pressure at other parts. A little nausea is excited by these manipulations, as well as by walking around.

Finally, we note that he has felt no pain at the back, and pressure does not occasion any unpleasant sensation.

The movements of the bowels have been irregular, always tending to sluggishness before the time he dates his present bad feelings; since then usually more closely confined, but this condition he tells you was interrupted by intervals when the movements were loose. So far as he can remember, the loose periods corresponded to occasions of greater pain and discomfort of the stomach. An evacuation of the bowels has occurred spontaneously —forty-eight hours since the vomiting of blood came—and he tells you it was moderately free and about as usual. There was no appearance of blood, no tarry matter in it, and subsequently none has been found. The matter passed was softly solid, varying in colour even in the same movement, but generally light gray, and oftentimes we have found scybalous

masses not of great firmness, and these as well as the softer feces were mingled with mucus.

Finally, let me call your attention to the general air of the patient—one who has never had a comfortable lot in life, and is now feeling, as he has been for several months, greatly depressed and despondent. It is well painted on his face. Doubtless from the recent hemorrhage he has been alarmed, but at present dejection is the prevalent tone. This depression comes in the high and low, the rich and the poor, and entirely apart from the accidental cause of alarm which this man has suffered. When the gastric discomfort, sometimes a burning pain, has been most marked, then has he been the most dejected.

Let us now briefly endeavour to determine the cause and the sort of trouble with which we have to deal. This history shows no antecedent acute disease, no intemperance, no excesses of any kind which so frequently lead to stomach maladies. A diet of materials largely difficult of digestion, badly prepared, taken hurriedly, and often at times when tired and exhausted with work. Add to this bad hygienic surroundings both for living and for work. Here are conditions which depressed the patient's strength below the normal, rendering the stomach unequal to performing the function of digestion. The same diet and the same conditions of life are continued, and digestion is each day an incompleted process, and consequently progressively less and less nourishment is derived from the food. Strength for digestion, as well as for work, becomes progressively less. This condition of affairs may continue in a naturally strong man for a considerable time unnoticed, as it doubtless did in this patient, for he, too, was formerly strong.

The next step in the process is, however, taken. A residuum of undigested food, however small, cannot be left in the stomach daily without producing a distinct effect sooner or later. What is this effect? First, on the mucous membrane. The presence of food in the stomach, under normal condition, excites its circulation, and this flow of blood is followed by secretion, and the digestion of the alimentary matters, and the prompt emptying of the organ. Then normally succeeds the ordinary quiet flow of blood, unattended with secretory activity, except a slight flow of mucus.

How is it with the stomach of a strong person when from any circumstance, over-eating, fatigue, nervous emotion, digestion is incomplete or delayed? After an interval, during which there may or may not be symptoms of indigestion, the digestive act recommences, the process is completed, and all is over. At most the evacuation of the bowels on the following day does not occur at the usual hour, or, with some, two movements result. Like the gardener who has not planted and cultivated his crop aright, harvest and seedtime are delayed.

Let this occur habitually in the debilitated. The repeated attempts to recommence digestion of this residuum are as ineffectual as the original effort, and for the same reason. The constant reflow of blood in these attempts leads to change of function, and the continued presence of undigested food acts as an irritant. The flow of blood never ceases, the epithelial and glandular arrangements never have intervals of rest for repair, and the chemistry of digestion is less and less well performed.

The principal product of the mucous membrane activity—over-activity—is, under these circumstances, mucus, and we have arrived at the border land of inflammation. However, gentlemen, we will not give it any name, but be content to understand what has been going on in this man's stomach. This abnormal amount of mucus, present nearly all the time, has another

very powerful influence for evil, viz., that the newly swallowed food is immediately immersed in a nearly inactive fluid, and thus surrounded the digestive juices are unable to act on it.

This is a process, therefore, you see, which is constantly promoting itself, and generally pushing forwards from bad to worse. Fortunately, this patient has largely escaped from one feature which so frequently comes in this condition, viz., the fermentation of the stomach contents. He has had no heartburn, no acid eructations, and but little bitter taste in the mouth. The formation of the various fermentation products, many of them of an acid character, develops and tends to render permanent the irritable conditlon of the mucous membrane, which I have described as bordering on inflammation, more intensely, and certainly more rapidly, than any other fault in digestion.

Now what has been the treatment? Let me say at once, as my remarks will already have shown, that we did not believe from the first that this man was suffering from gastric ulcer. The evidence of ulceration was never very strong, and if once we disbelieve the story of the hemorrhage, or at least discount the amount of blood, the indications of this condition almost disappear. You know how apt the laity are to exaggerate the amount of blood lost, and further than what the man himself told us, no evidence of hemorrhage appeared; no bloody or tarry stools were discovered. Whether ulceration actually occurred, or merely an escape of blood from the overdistended capillaries, no further hemorrhage came, and this, therefore, was not a symptom which had to be combated. The line of treatment which we proposed to follow was not inconsistent, at all events, with a possible ulceration, although perhaps we should have modified it had we been positive of its occurrence and of hemorrhage from that cause.

The man was put to bed, to rest, to quiet him, to quiet his circulation, to save his strength, and this was made absolute for a few days. Then he was gradually allowed to move about, and finally he was ordered exercise in the open air.

The food was entirely fluid—milk or milk and lime-water. Carbonic acid water is likewise useful. Later meat soup; beef tea is not well adapted to this condition. And still later the starchy foods and a little meat were cautiously added to his diet.

For the relief of pain and discomfort of the stomach, he was ordered dilute hydrocyanic acid. A blister, an inch square, was put on the epigastrium; not allowed to remain long; merely to redden the skin; and its position thus frequently changed. This was kept up for several days.

In the course of the week the patient was feeling much better, more cheerful; the sensation through the temples less constant, and not so discomforting; the tongue was cleaner but still coated at the back part, and looked fresher; the swelling not much changed; the bowels acted without assistance, but at long intervals; the upper part of the abdomen felt more comfortable; the vomiting, however, recurred again, but at much less frequent intervals.

The improvement was satisfactory, and was probably largely attributed to rest, the improved methods of feeding, and the better hygienic condition. A return to his former life would certainly have caused a renewal of his symptoms and discomforts. There was as yet no evidence of any essential change in the disturbed action of his mucous membrane. The tongue was still swollen, and furnished the ready index of a turgescence condition of the mucous membrane of the stomach. Is there nothing to be done to relieve or remove this condition beyond time and careful feed-

ing, and these two means are very powerful, nay, essential, if a permanently good effect is to be produced?

Yes, I think there are means to be employed—medicinal agents, which in the large majority of cases are effective in changing the action of the mucous membrane. Without their use, too, time and dieting are ineffective. In making selection of these agents, great difficulty is encountered often in finding the proper ones. This difficulty arises, I think, mostly from the lack of means of distinguishing the exact or even approximate conditions we have to deal with—and by this I mean more especially the grade or stage to which the morbid process has attained. Perhaps, however, this difficulty is not greater than with a similar condition of the respiratory mucous membrane.

One of the most efficient which I have used is calomel, and there is, I believe, nothing new in its use for this purpose. Note, however, gentlemen, the dose in which we administer it to this patient. He is to take the twelfth of a grain, in sugar, every three hours. In this manner we will continue with it until it produces an effect. This effect is often arrived at speedily, but more commonly slowly, and for permanency of result, I think the more slowly the better. It may be continued in this dose for weeks without salivation. The sensations which the patient describes after its use—and here I am speaking of the result in very numerous other cases—are, first, a relief from the feeling that has been present in the stomach; the pain is gone, though often it comes again; the burning, if there has been any, lessens and disappears; the weight or dragging is slowly removed; and a sense of content pervades the usually rather despondent person; and in describing the effect the hands are spread or rubbed over the stomach as expressive of comfort. Nausea and vomiting usually disappear from the first, even after a few doses of the medicine. The temple pain leaves.

Second. The next effect, often not arrived at for a week or ten days, or even longer, is a sensation which is diffused over the abdomen. Some patients describe it as activity of the bowels; others that "something is leaving;" to others it is a griping, as though from diarrhœa; and to others the sensation is almost nil, though they continue to improve.

What changes are observable in the patient apart from his sensations? First, he looks more cheerful; and the colour of the face, often muddy in these cases, clears. Second, the tongue clears off still more and more, or perhaps in the most successful cases entirely. The appetite and taste return or improve, and it is often difficult to restrain the desire for food. The diet, however, must for some time be kept absolutely restricted; nourishment given frequently and in small quantities, and nearly all fluid. Third, the tongue becomes less swollen, and loses the markings of the teeth along its border. The bowels are at first unaffected, but later the movements become more regular. Oftentimes there is what may be looked upon as a critical discharge, an unloading. This fecal matter varies very greatly in character; the element most generally common is mucus, and after this removal of mucus the abdominal sensations are more comfortable. The movements of the bowels previously to this discharge—which does not take place at once, but may be continued through several days—may have been of a diarrhœal character, or at least irregularly so, become at once more natural in time, quantity, and quality. More usually the bowels, during the early stage of the treatment, and indeed before, are constipated. The removal of the accumulated masses, often dry and

hard and scybalous, is a great source of relief, and after this digestion is much better performed, and the condition of the stomach improves.

In a word, I may say the result of the medicine given in these small doses, and even smaller ones often suffice, is regulative; if diarrhœa has been present, perhaps occasionally it disappears; if constipation, it is replaced by regularity.

Here is another man, still young, who looks old. Accustomed to hard work, he has now been overtaken with a stomach trouble which prevents labour. The immediate cause of his present trouble—or rather let us say what precipitated an exacerbation of his symptoms—was an apparent attack of intermittent fever. This malady you will not infrequently find does entail a catarrhal condition of the stomach. Why a mild attack of intermittent fever should do so more than other acute diseases, I can but offer this suggestion, viz., that during its continuance, the diet is generally less carefully regulated.

In this man's case I speak guardedly of his having had malaria at all, because I find a condition present in him which may have induced a mild febrile condition simulating intermittent; and then, too, quinine, we have found, did not relieve him. Stomach troubles of the sort this patient has suffered, you will find not infrequently produce pseudo-intermittent attacks.

Look at this man's mouth. There is not a tooth in the lower jaw capable of biting or grinding, and on the upper jaw it is not much better. I have not been able to get from him a satisfactory history of his stomach; he does not seem to be able to tell; but it is self-evident that digestion could not have been well performed, since the first step in its performance, with ordinary diet, was not effected. Food, not masticated, is a fruitful and frightful cause of diseased stomachs.

Whether this man suffered malaria or not is, so far as his stomach is concerned, a matter of small importance to ascertain; for, sooner or later, gradually or suddenly, he was sure, without extreme care, both as to mode of life and diet, to suffer disordered digestion and organic changes in his digestive apparatus.

With this imperfect history I shall not stop at the detail of his symptoms, but merely summarize the probable course of events and speak of the organic alteration with which we have to deal. The unmasticated food created the same inflammatory, or catarrhal, or mucous condition of the stomach as in the previous case. The partly digested pulpy food was forced into the bowel—this man, according to his account, had not suffered from weight, acidity, or vomiting previous to this attack, but had had an irregular diarrhœa.

Why this man's stomach has been able to void its contents, though undigested, promptly, and another man's has not, I am unable to say. Perhaps there was an original difference in the strength (muscular strength) of the two stomachs, and this man is evidently a more powerful man originally than the other. Certain it is, however, that some stomachs have this expulsive power more than others. I have witnessed the effects during life, and every one who is habitually examining stomachs microscopically will see differences in the muscular development in the various specimens.

The prompt expulsion of the undigested food saves the stomach from much damage, or, at least, discomfort, as it has saved this man. As he tells us, he was unconscious of any trouble with his stomach until this attack. Now, however, as you hear from him, as you may see, too, from his face, his stomach has given out. Watch me while I percuss the abdomen, and you can almost hear the evidence of the "giving out." The

area of the tympanitic stomach clearness is, you see, greatly increased. We, therefore, have to do with a dilated stomach.

There is no evidence that the pyloric opening is obstructed. There is no tumour to be felt, and I could easily reach it through his thin abdominal walls. The onward flow of his food and of the secretions of the stomach is delayed not by obstruction, narrowing of the outlet, but by deficient expulsive power. We have been washing out the stomach with the siphon, and here I show you the character of the matters that have just been removed. Besides the acid smell, note particularly the amount of mucus, now of course largely diluted with water. You at once see, from the foul, unnatural condition of the cavity of the organ, how nearly impossible it would be for even fluids, like milk, to be digested, and how wholly impossible for a solid, like meat, which this man cannot chew, to be digested,—first, from the failure of the juices, secondly, because, from the dilated condition of the organ, the digestive churning does not take place.

I think you will agree with me when I say this stomach has given out —given out in one of its most essential particulars, viz., its muscular apparatus. There is nothing I can so well compare this stomach to as a heart with valvular disease. In spite of the damaged valve the increasing strength of heart-muscle, hypertrophy, is able to overcome the obstruction to the onward flow of blood, but as soon as the cavity dilates then result symptoms of impeded circulation.

Is there anything we can do for this condition?—and remember what it is we have to deal with—first the catarrhal mucous membrane, second the defective musculature. I don't know how much benefit we can afford this man, but will give you the line of treatment we shall follow, and report the result on a future meeting.

For the mucous condition I have already told what we want to do, but those remedies are hardly in place at this stage, and it is only later that we can avail ourselves of that plan of treatment. I don't think dropping a little pepsin or mineral acid is going to avail much. They would be lost in the sea which we have just removed from this man's stomach. A better plan, perhaps, would be to administer food already partially digested. The antiseptics and non-fermentatives will not be remedial, though they may conduce to the patient's comfort.

The chief condition here is the dilatation, and we will continue to remove the load from the organ by the siphon, and give the enfeebled muscular apparatus the most favourable opportunity to contract and regain its normal tone. Is there any medicinal agent, which, like digitalis for the heart, influences directly the stomach? We do not know of any, but the medicine which, in my hands, has done the most good is nux vomica and its alkaloids. Tincture of nux vomica has long enjoyed a reputation in stomach disorders of various kinds, but how much it will effect in this case I am not able to say.

In other cases where I have had to contend against the food delaying in the stomach, this remedy has proved very serviceable. And in patients suffering from the catarrhal trouble, but in whom no dilatation of the stomach is present, a combination of calomel and extract of nux vomica is exceedingly useful.

Let me now show you a specimen recently removed from a patient who had long suffered from a catarrhal inflammation of nearly the whole length of the digestive tract. This stomach will serve as a diagram, bringing out in an exaggerated manner the changes of which we have been speaking. We find it filled with thick mucus, adhering to this almost destroyed

mucous membrane. The submucous connective tissue is very greatly increased. It is from the fibrous change of this portion, through which, you remember, the capillaries run, that the mucous membrane has been destroyed. Its supply of blood has been cut off. Look, too, at the muscular coat, how enormously hypertrophied. Some portions measure a quarter inch in thickness. For the present purpose of our illustration I need only state that this patient did not suffer from symptoms of retained and undigested food—there was no vomiting, no acidity, no heartburn, no eructation of gases. He had a sense of weight, and often burning at the epigastrium, but no other of the ordinary symptoms of dyspepsia. In fact all his food seemed to be hurried through the stomach unchanged, propelled onwards by the increased muscular force of the organ.

Let me sum it up. Stomach disorders, usually accounted functional, as well as others, are essentially catarrhal in their type. The presence of increased quantities of mucus is, in the early stages, one of the chief causes of the failure of digestion. This catarrhal condition, unless promptly checked, leads to organic changes, the most important of which affect first the submucous connective tissue, and secondly the muscular apparatus. The changes in the epithelial structures, of course the initial step in the catarrhal process, are much less important than the others, because complete restoration of the epithelium is more readily effected. The stomach, like the heart, exhibits its most disordered phenomena when the muscular apparatus is defective or begins to fail, and that the improvement or hypertrophy of this structure saves, at least temporarily, much discomfort to the patient.

The essential point in treatment is to change the morbidly catarrhal or mucous action of the stomach, and with the restoration of this action to the normal comes, and by this means alone, an improved quality of digestive fluid. In the presence of the mucus the digestive agents are not able to act. Finally, the addition to the dietary list of pepsin, mineral acids, antiseptics, and anti-ferments, however useful in temporarily assisting digestion, and however comfort-giving to the patient, is not curative.

CLINICAL LECTURE ON THE USE OF SPONGE PRESSURE AS A SURGICAL DRESSING.

Delivered at the Royal Infirmary, Manchester.

By JAMES HARDIE,
Assistant-surgeon to the Infirmary.

Gentlemen: A week ago to-day you saw me amputate the leg of a man, aged twenty-five, through the knee-joint, for gangrene, occasioned, as we believed, by embolism from cardiac disease. I dressed the stump in your presence, and I stated that I hoped to be able to-day to make some remarks to you on the special kind of dressing which I then employed. You will be interested to learn that from that time to the present the dressing has not been changed, and not only so, but that there has been no indication for a change of dressing. Not a stain of discharge has been visible; there has been no pain in the stump; the temperature has never been more than one degree above normal; and, in fact, the patient at our daily visit has invariably expressed himself as being quite well. Now, accustomed as you are to see the dressings of an operation changed almost daily, during at least the first week, this brief narrative cannot but be remarkable to

you; and as this is no solitary case of the kind, but one of many, I am desirous of drawing your attention to the lessons which may be learned from it.

It is scarcely necessary that I should justify myself when I say that the ordinary methods of dressing operation cases, whether antiseptic or otherwise, are by no means perfect. To many minds the mention of antiseptic dressings conjures up an infinite amount of trouble and pains and pitfalls. The trouble and pains we might leave out of account, as they soon become a second nature to us, though, for all that, we should be glad to be relieved of some part of them. But, then, every time the dressing is changed the patient is distressed, and there is also a risk of something going wrong. Certainly the handling of the part is not conducive to healing. Quite the reverse, for it may injure recent union. Possibly septic material may gain access to the wound, and the treatment so break down. But still, though everything goes on well, this repeated changing of dressing has to go on too; and, as I have said, every surgeon admits that this is itself an evil, and the less often he has to do it the better is he pleased.

Let us consider, then, what are the conditions of a wound, say an amputation stump, which require this frequent change of dressing. Dressings are changed because of the amount of discharge which has escaped into them. Whence this discharge? What does it consist of? You cannot inflict a wound, however small, on any part of the body without the speedy occurrence of two phenomena —first and immediately the effusion of blood, and second and later the effusion of material for the healing of the wound. Now, this effused blood and so-called inflammatory material constitute the discharge we have to deal with. The former generally early ceases, but as regards the latter, its quantity and quality also depend greatly on the conditions of the part implicated. For instance, you know that in operations on the lip—as for harelip—when the edges have been brought accurately together no great amount of discharge takes place, and union of the wounded surfaces is soon accomplished. Here we have a tissue which is dense and firm, and affording little room for the accommodation of extra-vascular discharge. In the case of a wound under the eye, again, you know that it is followed by a large amount of swelling of the adjoining parts, and this is due to the fact that here the tissue is loose and cellular; and we find, as a matter of fact, that under ordinary circumstances the healing of a wound in this region is accompanied by the filling up this loose cellular tissue by extra-vascular effusion. This takes place in the case of all wounds in this region to a greater or less extent, but the extent is much less in the case of a clean incised wound than in that of one which is contused or lacerated. If the surgeon has brought the edges of the wound accurately together, and the effusion be large in amount, a further train of phenomena will then probably ensue, which are referable to the tension of the tissues, and which you are all familiar with as acute inflammation. Bearing these cases in mind, then, and reverting to that of the amputation stump, we find that we have an extensive wound through tissues of various degrees of density, some being tough and unyielding and some loosely cellular, while the surfaces of the wound are so uneven that when brought together they afford a multitude of pockets and corners which in ordinary will be filled up by discharge of one kind or another. The wound being an extensive one, and there being considerable bruising of tissue by sawing the bone and ligaturing or twisting the vessels, it is to be expected that the discharges will be somewhat abundant in all cases; and if the surgeon, forgetful of this, neglect to make due provision for its escape, disastrous consequences will probably ensue. Hence the use of drainage-tubes of one kind or another. But a drainage-tube cannot be looked upon as an innocuous body in a wound. However beneficent its purpose, it is to all intents and purposes a foreign body, and as such must create some degree of irritation, increasing by so much the amount of discharge. A drain, then, is to be regarded

as an evil, except so far as it prevents a greater evil. And here I may remark, somewhat parenthetically, that the present fashion of using drains almost up to the very closing of a wound, the end being clipped off every few days as the latter fills up, although interesting enough, has always appeared to me most inartistic. Is there nothing better than this mere playing with nature?

We have now to consider the behaviour of those effused products—the blood and the inflammatory discharge—in regard to the healing of the wound. The blood which remains between the flaps of course first coagulates, and a large proportion of the fluid portion early escapes from the wound. The clot itself may either break down, and also entirely escape from the interior, as it probably does when it is large, or if small and spread out it may, as it is said, become "organized"—that is to say, it affords a nidus or support for the new interlacing tissue which ultimately unites together the opposed surfaces of the wound between which it lies. Day by day it loses more of its serum, and becomes more firm, and ultimately, when it has been brought completely under the influence of the tissues, it is probably entirely absorbed. It is unnecessary for us to consider whether, as some maintain, the clot itself ever contributes actively to the formation of the new connecting material. This you have doubtless had fully discussed in your pathological studies. Enough that it is unnecessary, and that it interposes itself as an obstacle to the immediate union of the cut surfaces, and thereby throws on them the necessity of elaborating a larger amount of new growth than would be otherwise required. As regards the inflammatory material—the serum and plastic exudation—you will understand that in such parts of the opposed surfaces as are somewhat firm and closely applied to each other, barely more is here thrown out than is actually required for immediate union, while into the loose cellular interspaces, and more particularly into the nooks and crannies of the wound, which have not become occupied by blood, a continuous flow of this discharge goes on, in daily decreasing quantity, until by the shrinking and consolidation of the plastic material, aided by the contraction and compression of the surrounding tissues, this material fills up all these interspaces with firm new growth. This itself after a time becomes absorbed, but not always readily; and you will commonly find stumps which have recently healed somewhat full or rounded, and not seldom will you find the subcutaneous cellular tissue occupied by solid new material, which not only disappears slowly, but renders the stump incapable of support. What we find, then, to take place in the healing of wounds is that parts which are closely in apposition unite by immediate adhesion, while those that are separated by an interval, and lack support, unite by the effusion of material from the vessels, a large proportion of which, being fluid, is thrown off as discharge, and that the greater this interval, and the looser the tissue, or, again, the greater the amount of damage done to the part by the operation, the larger is the amount of this discharge, and the longer does it continue.

Now, I do not suppose that any of you will pretend to think that this is a typical mode of healing. What is a typical mode of healing? Do we not regard the absence of all discharge and primary adhesion of the wound surfaces, as you sometimes see in small cuts, as the *beau idéal* of the healing process? Cannot we do something more in our dressing of large wounds that their healing may imitate more closely this *beau idéal?* This is what, as intelligent beings, we have to aim at.

I have described to you the method which nature adopts to unite wounds which are held together by sutures and dressings as usually applied, and I have insisted especially on the fact that the discharges we are accustomed to see from wounds are due to the exudation of material into the cellular tissue, and into the loose vacant spaces between the surfaces of the wound. Now, I want you to understand and believe that this discharge is entirely unnecessary for the healing of

wounds, and that, were it not for the existence of these loose interspaces which I have mentioned, it would cease to trouble us. This is the point, gentlemen, which it seems to me we have forgotten in our daily surgical life, but forgetting which we have altogether missed the mark to be aimed at in our labours towards perfecting dressings. We have laboured to invent dressings which shall absorb the discharges; what we have to do is to devise dressings which shall render discharges unnecessary. Consider for one moment what it is you desire to do in arranging a stump after amputation. Do you not wish to place the entire wound surface in intimate apposition, and to maintain it so until it has adhered together? If this be so, you can imagine how little likely your ordinary dressings are to carry out your intention. You leave large spaces in the cavity of the wound, particularly at the angle where the bone is situated, and you leave loose connective tissue everywhere, both of which will quickly become occupied by effusion from the vessels. Clearly what we have to do to secure our end is to employ dressings which will exercise a sustained external pressure sufficient not only to bring the opposite surfaces immediately into contact, but also for the time being to obliterate the cellular spaces of the connective tissue, and to prevent the subsequent effusion of blood or inflammatory products. As regards the arrest of hemorrhage in this way, your every-day experience will remind you that it is easily enough accomplished, and we need not therefore pause to consider it. But as regards the prevention of inflammatory exudation by pressure, some theoretical objections will probably occur to you. Remember, however, that we are not dealing with tissues already the seat of inflammatory disturbance, but with tissues in their normal condition, and that we seek to prevent even the first step in the process. That this may be accomplished by means of pressure, in certain cases, is evidenced by the treatment of fractures and sprains by the early use of judiciously applied compresses.[1]

For some years past I have been endeavouring to dress wounds with the end in view which I have enunciated, and, not to take up time with the record of failures, I find now that I have so far succeeded that I am justified in bringing my present method under your notice. I have found, that, by the use of sponge bandaged over the surface of the stump or other part, one is often able to secure perfect union of a wound without discharge and without the need of changing the dressing until the union is complete and sound. Sponge, as you know, is a material which is readily compressible into a very small bulk, and which also possesses a high degree of elasticity or resilience, so that pressure being removed it immediately resumes its former size and shape. Besides this, its highly absorptive properties, which are commonly taken advantage of in surgical practice, are well known to all of you. For these reasons sponge appeared to be a material well adapted for the purpose I had in view, first and chiefly, to exercise a continuous and elastic pressure, and, secondly, to absorb readily any discharge which might perchance escape from the wound. The sponge I have hitherto mainly employed has been the large-celled honeycomb, and the manner in which I used it is briefly as follows. Antiseptic precautions are used throughout. All bleeding points are carefully closed. Frequent sutures are inserted, so as to bring the edges accurately together. No drainage is used. The sponge, having been soaked in carbolic lotion, is squeezed tightly to expel every drop of superfluous moisture. The flaps of the stump are meanwhile carefully pressed together by the surgeon in order to force out any blood which may have collected during previous procedures. And let me urgently draw your attention to this point, since want of thought about it will frequently cause disappointment. However care-

[1] Vide Mr. Sampson Gamgee, Fractures of the Limbs; also Mr. R. Dacre Fox, Brit. Med. Journ., vol. ii., 1880.

fully you may close all bleeding points in an amputation, in nine cases out of ten you will find that after closing the wound some further hemorrhage will have taken place. Possibly this may be from the surface of the flaps; very probably it may be from the needle punctures. But be that as it may, to leave this blood in the cavity is to court failure. Diligently compress the flaps together with your fingers, and so squeeze out every drop of blood; then relax not your hold for an instant, but skilfully place the compressed sponge over the surface, and hold it, and as many more sponges as may be required to cover the entire surface, tightly with your fingers, while an assistant secures them in place with a bandage. Sometimes this is rather difficult to do, but by stitching sponges together some assistance may be gained. The bandage having been applied, you may now cover the whole with antiseptic gauze, or with tenax, with a piece of mackintosh over all; these again are secured with another bandage. In many cases it is advantageous to use as a bandage a piece of elastic webbing. This you may do if you choose.

Now, in the case of a wound of moderate size, as in the removal of small tumours or in operating for strangulated hernia, I am almost always satisfied that dressed in this way my care for it is at an end. A few weeks ago I removed a fatty tumour the size of an orange from the shoulder of a woman downstairs. The dressing was not removed until ten days afterwards, when the wound was found perfectly united and dry. So with three cases of hernia I have recently had: one a woman downstairs, and two men in the adjoining ward. In all these cases no further care was needed except the removal of the sutures when the dressing was taken off, ten days afterwards. There are also at the present time two cases of hernia in the men's ward dressed in this way. One was operated on two and the other three days ago. Both are perfectly well, and I advise those of you who are interested to look out for the removal of the dressing, probably on this day week.[1] In the case of large wounds, however, as in an amputation of a fleshy thigh, the case is very different. Here considerable skill is required in the proper application of the dressing, and doubtless in many instances only partial success will be attained. For example, there is a boy downstairs whose thigh I amputated in the lower third thirteen days ago on account of a smash of the leg. From the night of the operation he has been perfectly well. He has never once complained of pain, and, as you see from the chart, his temperature only once reached 100.2°, and has averaged 99°. This entire absence of symptoms caused me to think that on removing the dressing I should find complete union of the wound. On the tenth day, however, the nurse perceived some discharge oozing from the dressings. I therefore removed them, and found some bloody serum trickling from between two of the sutures. At one corner, also, there was some fulness perceptible. On further examination I found that a clot of blood had lodged here, the serum from which had been slowly oozing into the sponges, which, by the way, were wet and heavy. This case is an example of want of skill on my part in the application of the dressing. I do not altogether regret it, as it affords to you a good instance of the readily absorptive property of sponge.

[1] One of these men complained on the third day of pain in the region of the wound. This, it was thought, was probably due to flatus; but lest there might be any inflammatory action the dressings were changed. The wound was found perfectly sound, however, and an enema having been administered the uneasiness passed away. In both cases the dressings were removed seven days afterwards. In the case which had not previously been changed, everything was found as it should be—the wound healed, and the surface of the sponge covered with a little dried-up blood. In the other the lower end of the wound was somewhat inflamed; three-fourths of it, however, were perfectly sound.

You will now have an opportunity of seeing for yourselves the result, a week after operation, in another case of extensive wound—in the man, namely, whom I referred to at the beginning of my remarks. Although I should otherwise have left the case alone for some days, that the new tissue might be consolidated, I will take this opportunity of giving you ocular demonstration of how the case has thus far gone on. At present I cannot say with certainty what condition we shall find the stump in any more than any one of you can; but, judging from the general condition of the patient, I can form a pretty safe surmise that there can be nothing very far amiss. [Dressings removed.] You will see, gentlemen, how entirely satisfactory the progress of this case has been. There is not the slightest swelling or semblance of inflammatory action in any part. The flap is closely applied to the bone, showing everywhere the normal contour of the articular surface, the edges of the wound seem united, so that we will remove the stitches, and on the surface of the sponge lying over the wound there is only a little dark-coloured discharge, which has now nearly dried up.

I do not disguise from myself the fact that in this amputation (through the knee-joint) we have not a quantity of vascular tissue to deal with, nor the further fact that in this particular patient the blood pressure in the part is probably less than normal on account of probable plugging of the main arterial trunk. But, on the other hand, we have here a very uneven surface to cover with the flap, and under ordinary circumstances we should probably have had the depressions filled with a quantity of soft new material. And so the case may he regarded from this point of view as somewhat crucial.

I might refer to some other instances in which almost equally satisfactory results have been obtained, especially to two of amputation in the middle of the thigh which I performed elsewhere, and in which the pressure was effected through the medium of finely prepared oakum, not a very satisfactory material, as it lacks the resilience of sponge and soon becomes caked. Not having notes of the cases, however, I shall not draw on my memory for further remark.

Gentlemen, without the great fact of antiseptic surgery, to my mind the greatest achievement which has ever been accomplished in the whole history of the art, all this would be impossible.[1] Without it we pursue a course at best uncertain, and often dangerous, while with this safeguard we go on with secure step, and shall doubtless obtain more and more mastery over those abnormal occurrences which still too frequently impede our path.

Of other instances in which sponge pressure may profitably be had recourse to, I may have something to say on a future occasion.—*Lancet*, Oct. 15, 1881.

Hospital Notes.

Aneurism of the Subclavian and Axillary Artery treated by Galvano-puncture.

C. R., a seaman, aged sixty, was admitted into Mr. RANSFORD'S ward at the Royal Southern Hospital, Liverpool, October 21, 1879. Two years before he fell and injured his left shoulder. Nine weeks before admission he noticed pain for the first time in the left shoulder. About two weeks ago he noticed a swelling for the first time under the clavicle; and that his hand and fingers tingled and

[1] Yet possibly this is not the whole truth. It is known (*vide* Dr. Wm. Roberts, "On Spontaneous Generation, and the Doctrine of Contagium Vivum") that septic germs are harmless in the living tissues, and it is thus possible that the careful prevention of useless exudation into a wound may place it in a condition which will enable it to resist their further development even in the absence of antiseptic measures. But in spite of that, the possible collection of discharge through the inadequacy of our dressings will always render the use of antiseptics a desirable precaution.

felt numbed; his left arm was also colder than the right, and had shooting pains down the arm. These symptoms gradually increased, and the swelling got larger and the arm became weaker. There was no history of syphilis.

On admission, he had a pulsating tumour extending from the left clavicle downwards a distance of four inches. On auscultation, a loud bruit was heard from the clavicle to below the level of the tumour. The left shoulder and arm were œdematous, and colder than the right: and there were shooting pains down the left arm, and over the shoulder-blade numbness and tingling of the fingers. Pulsation extended above the clavicle. The pulse in the left wrist was much quicker and weaker than in the right. Left arm ten inches round; right nine inches. Ordered iodide of potassium, five grains three times a day, and hypodermic injection of morphia, one-fifth of a grain at night.

Nov. 5th. The tumour seemed to be rapidly increasing in size. Thirty grains of iodide of potassium were given three times a day. In the afternoon two insulated needles connected with the two poles of a constant current battery were introduced into the tumour; ten cells were employed. The kneedles were kept in for rather more than thirty minutes, whilst the man was under the influence of ether. During the afternoon and evening the pain in the shoulder was about the same as before. Ice applied to the tumour. On the 6th, the pulse was 84, temperature 97°. Pain in the shoulder no less. No apparent change in the size and consistence of the tumour; pulsation in it and the radial quite as strong. No redness round the needle punctures. No headache. On the 7th he passed a good night after hypodermic injection. Solid feeling around both punctures and tumour, otherwise it appeared the same. Pulsation quite as strong. He went on in this way without much change till the 15th, when two needles were introduced, about three inches in depth; fifteen cells were used, for about forty-five minutes. Ice omitted. Pulse in the evening 112, temperature 99°. Pulse and temperature remained about the same till the 18th, on which day the pulse was 120, temperature 98.4°; 19th, pulse 110, temperature 98.4°. On the 20th the pulse was 116, temperature 98.6°. For the last few days there had been great numbness in the hand. Hand and arm swollen and powerless. Red blush over arm. The tumour was in the same condition; no signs of consolidation. Pain was very severe at the back of the shoulder-blade at night. Evening, pulse 130, temperature normal. Ordered one grain of extract of opium every four hours, as the hypodermic injections caused irritation of the skin at the point of insertion. On the 22d there was puffiness round the shoulder and axilla; arm still painful. Pulse 120, temperature 99.2°. On the 26th he had severe pain during the night, and this morning at the lower border of pectoralis major. Swelling in axilla extending down the side. Ordered fifteen grains of chloral hydrate and twenty grains of bromide of potassium at bedtime. Arm strapped to the side. Pulse 120, temperature normal.

Dec. 3. Restless during the night, shouted and got out of bed; quite awake at the time. In the morning pupils were not equal, left smaller than right, neither acted well to light, sight of left eye not so good as right. Pains in arm and shoulder not so severe as usual. Tumour still increasing. Has slight cough. On the 4th the operation was repeated with twenty cells without much hope of doing any good as only negative results had followed the former operations, but the good results obtained by Dr. John Duncan, of Edinburgh, encouraged another trial. For a day or two the tumour felt firmer, but this was only transient, and all melted away again. On the 9th the chloral was increased to twenty-five grains at bedtime, pain was very severe, and without chloral he was very restless. The tumour was gradually increasing. On the 17th the house-surgeon reported that there was no pulsation in the tumour, and he feared rupture of the sac of the aneurism. On examination pulsation was hardly to be felt, the tumour was

more diffuse; no pulse could be felt in the left radial; pulsation felt best at the inner side of the tumour, elsewhere hardly to be made out. Ptosis of left eye. Left pupil still contracted more than right. The arm was very œdematous, small gangrenous spots were visible on the back of the hand and knuckles, small slough over spine of scapula, loss of sensation three inches above the elbow. Intercostal spaces filled on expiration, sank in on inspiration. Breath-sounds were heard all over the chest. Left side of chest was very much flattened. Temperature 101.2°, pulse 124. In the afternoon he had a sudden attack of dyspnœa with profuse sweating. This passed off in about an hour. On the 18th he was delirious during the night; in the morning the breathing was quiet; no delusion; pulse felt again in the left radial; in the evening he had severe pain, and was ordered twenty minims of sedative solution of opium at once; pulse 100. Temperature, morning 96°, evening 100°. On the 19th he passed a fair night; less pain this morning: the skin in axilla red and inflamed; not much change in the tumour since the 17th, beyond that the skin was more distended, and the blood seemed to be finding its way under the skin down the side of the chest; no change in pulse and temperature. On the 20th a bleb formed on the front of the wrist; the hand looked very dusky; the patient appeared brighter. Pulse 100, morning and evening. Temperature: morning 99.4°, evening 101°. On the 24th, the house-surgeon reported that in the morning oozing of bright arterial blood took place from the axilla; parts very sloughy; stopped with a pad of lint steeped in a solution of perchloride of iron, and on moving the patient a large stream of dark blood jutted out from the slough over the scapula; this was also stopped as above, and with tenax. The patient died the next day.

Necropsy, the day after death.—It was noticed that the chest-walls at the upper and outer part were very much pushed in, but there were no signs of any absorption or erosion of the ribs. On carefully dissecting the tumour it was found to involve the whole of the third portion of the subclavian, and the first and second parts of the axillary artery. On dividing it vertically it measured seven inches in diameter in its long axis, and four and a half antero-posteriorly. The anterior portion of the sac was lined with laminated clot, varying in depth from one to two inches; this in one or two places had broken down and formed small abscesses, apparently at the points of puncture; the sac had given way at the lower portion, and communicated with the slough in the axilla. Posteriorly the aneurism extended back to the scapula, and the tissues behind were infiltrated with dark blood, but there did not seem to be any rupture of the sac in this direction, and there was no direct communication with the slough over the scapula. The aorta and the larger vessels were atheromatous, but the other organs of the body seemed as sound as could be expected in an old man of sixty.

Remarks by Mr. RANSFORD.—It was only after many consultations with my colleagues that I decided to try galvano-puncture. The only other alternatives seemed to be to leave him to his fate, or amputation at the shoulder. Dr. John Duncan, in a paper published in the *Edinburgh Medical Journal*, April, 1866, gave fifty cases treated by galvano-puncture, of which twenty-three were cured. These results inclined me very strongly to give it a trial in this case, but I think the lesson it teaches is that in an aneurism of such magnitude galvano-puncture alone is not enough. I should in any similar case be disposed to recommend amputation about the shoulder as a preliminary step, and combine it afterwards if necessary with galvano-puncture; or, as in Mr. Heath's plan (see the *Lancet*, Jan. 31, 1880, page 168), the simple introduction of plain steel needles, which were left in some time. This case also illustrates some of the drawbacks so well stated by Dr. Duncan—namely, that, "1st. It is inherently uncertain, liable to cause relapse by the melting of the coagulum, or inflammation by its sudden deposition. 2dly. It is very liable to set up inflammation in the walls and contents of the sac and surrounding tissues."—*Lancet*, Sept. 24, 1881.

MONTHLY ABSTRACT.

Anatomy and Physiology.

Influence of the Nerves of the Tympanic Cavity on the Vascularity and Secretion of its Mucous Membrane.

E. BERTHOLD summarizes the results of a number of experiments as follows: first, that lesions of the trigeminus, both at its trunk and its roots, provoke inflammatory symptoms in the middle ear; but there are differences in the sequels, according to the location of the lesion. The greater intensity of the inflammatory affection occurring after intracranial division may be explained by the prolonged duration of the inflammation. After semilateral division of the medulla oblongata the animals die too quickly to permit the inflammation to reach its height. Still more noteworthy than the difference in the intensity of the phenomena, is the condition of the bulla of the uninjured side. Differing in this respect from intracranial division, there was found as a result of semilateral division of the medulla oblongata almost invariably some secretion in the bulla of the sound side. Inclined though we were at first to regard this disturbance in the lining membrane of the middle ear as a sympathetic one, we still found no reason for the fact that such a sympathetic inflammation never occurred after injury to the trunk of the trigeminus, and we must leave it an open question whether perhaps a crossing of fibres takes place in the medulla, and a part of the trigeminus fibres extends to the middle ear of the other side. The acceptance of the latter assumption would make it self-evident that a lesion confined to one half of the medulla oblongata would affect both ears in the same manner, although in varying degree.

The investigations taught us, moreover, that the sympathetic must be regarded as a vaso-motor, and, according to the extent of our experiments, as an exclusively vaso-constrictor nerve of the entire ear, because a distinct narrowing of the auricular vessels was always observed after irritation of the sympathetic. On the other hand, we obtained negative results respecting the state of the vessels after irritation of the trigeminus as well as after injuries to the sympathetic, trigeminus, and glosso-pharyngeus. Prussak has already called attention to the fact that the constrictor action of the sympathetic, after its irritation, should lead us to suppose a dilatation of the vessels of the ear after paralysis of this nerve; the more so, as we know that division of the sympathetic is followed by filling of the arteries in other parts of the head. However, we fully concur with Prussak that the experiments have not borne out this supposition. Contrary to our expectation, the mucous membrane of the middle ear remained invariably pale, even when the division of the sympathetic had preceded the examination of the drum cavity by several days.

The most surprising result of our investigations, however, was the negative state of the middle-ear vessels both after irritation and after paralysis of the trigeminus, for soon after division of this nerve neither dilatation nor contraction of the middle-ear vessels could be observed. Nor could we, as stated before, observe any visible alteration in the fulness of the vessels by irritating this nerve. Although we could ascribe to the trigeminus neither vaso-constrictor nor vaso-dilator qualities, while division of its trunk or injury to its roots was regularly

followed by inflammatory phenomena in the middle ear, it appeared reasonable to acknowledge, in this case, the influence of the neurotomy as a merely trophic one, that is to say, to refer it to the existence of special trophic nerves. If we compare the process in the drum cavity with the so-called trophic keratitis, the phenomena in the drum cavity—protected as it is from injurious atmospheric influences—permit our drawing a more unambiguous conclusion in regard to the existence of these nerves—hitherto always considered doubtful—than the consequences of division of the trigeminus in the eye, which certainly permit of several interpretations. A traumatic otitis after division of the trigeminus could not be thought of, for reasons stated.—*Archives of Otology*, Sept. 1881.

Electrical Tetanus.

M. RICHET has found that strong and repeated electrical stimulation will cause, n rabbits and dogs, a tetanus comparable in its results to the traumatic form, and therefore of some practical pathological importance. As a rule rabbits die from asphyxia, and dogs from hyperpyrexia. The asphyxia in the rabbit is due to the arrest of respiration in consequence of the tetanus of the thoracic muscles, and death may be prevented by artificial respiration. Death occurs much more rapidly than in asphyxia from obliteration of the trachea. The latter only kills in three or four minutes, but the electrical tetanus kills by asphyxia in one minute; this rapidity of death is ascribed to the absorption of oxygen and liberation of carbonic acid during the general muscular tetanus. Prolonged applications may, however, exhaust the muscles, so that the contraction of the thorax may cease, and it is even said that respiration may recommence during the passage of the current, probably by the agency of muscles which have not been tetanized. Animals so exhausted cannot be killed by strychnine, if the application of electricity is continued. A rest of a few seconds permits the current to be again effective. In the dogs the electricity employed was not sufficiently powerful to arrest respiration, and death was due to the elevation of temperature. The ascent of the thermometer was extremely rapid, sometimes three-tenths of a degree per minute, so that after the tetanus had lasted for half an hour the lethal temperature of 111° or 112° F. was reached. This pyrexia is due entirely to the muscles, and not to the nervous system. Chloralized dogs, in which reflex action is abolished, present the same elevation of temperature, which occurs, however, a little less rapidly. The proof that the increased body-heat is the cause of death is furnished by the fact that if the animal is kept cool by artificial means, it may bear for more than two hours extremely strong currents, which cause severe tetanus, without dying for some days. The capacity for generating this great temperature under electrization does not disappear even after a prolonged application, and it is not influenced by previous fasting for two or three days. The curve of the rise presents at first a gradual ascent, which becomes more and more rapid, especially after the temperature of 101° is passed. Usually death occurs when a temperature of 112° is attained, but in some cases it reached 112.5° and 113.3.° If the temperature did not rise above 110° death did not ensue on the same or the following day; after this point, however, although death may not be immediate, it occurs within twenty-four hours. The electrization does not cause the acceleration of respiration, but this is due to the increased temperature. The thermic dyspnœa commences at 105°. and at 111° the breathing is so frequent that it is hardly possible to count it, and so feeble that scarcely any air enters the thorax. M. Richet believes that these experiments justify the hope that by treating the asphyxia and pyrexia death may be prevented in ordinary tetanus. There is one difference between the facts he observed and traumatic tetanus,

which suggests important differences between the two forms—namely, that in the latter the temperature continues to rise after death. This was not noted in their experiments, and it suggests that the cause of the pyrexia, and therefore its treatment, may not be the same in the two sets of cases. Moreover, death may occur in ordinary tetanus from exhaustion, without hyperpyrexia. Recognizing this difference, however, the facts ascertained certainly indicate the importance of keeping down the temperature in those cases in which it exhibits a tendency to rise to the extreme height often attained.—*Lancet*, Sept. 17, 1881.

Materia Medica and Therapeutics.

Action of Berberin.

Berberin has been recommended in Italy as a remedy for enlargement of the spleen consequent on malarial disease; and its mode of action has been carefully studied by Dr. A. CURCI, who has made with it a series of experimental, microscopic, and spectroscopic researches. An analysis of his memoir is given in *Lo Sperimentale* for August. He describes first its local and afterwards its general action. The local action of berberin, he says, may be said to consist in irritation and subsequent induration of the tissues. Thus the blood coagulates in the capillaries to which it is applied; the red corpuscles become small, nucleated, granular, and have pale outlines; the muscular fibres lose their distinctness; sometimes the striated fibres become larger and more marked, then lose the transverse striæ, and, the muscular substance coagulating at intervals, special enlargements are produced; the smooth fibres show distinct nuclei and become tortuous. All the tissues are hardened and strongly coloured by berberin; their vital properties are also increased, and there are active proliferation of connective tissue and increase of fibrous tissue. Berberin produces contractions of the intestine, secretion of mucus and of intestinal juices, and tonicity of the tissues. In studying the general effects of berberin, Dr. Curci first tried its effects on healthy animals. In all classes of animals, it produces prostration, muscular relaxation, adynamia, collapse, progressive lowering of temperature, at first increased and afterwards diminished frequency of the heart's action and of respiration, serous diarrhœa, albuminuria, fatty degeneration of the kidneys, and complete anorexia. Hypodermic injections produce these phenomena rapidly, and, if repeated, are followed by death. On the other hand, the administration of berberin by the mouth requires a larger dose for the production of the symptoms; diarrhœa and renal changes are always absent, and death seldom occurs. Towards the end, when sensibility is somewhat diminished, there are tonic and clonic spasm. The temperature is at first lowered, then returns to the normal, and finally falls as death approaches. The vomiting is constant and painful, preceded by contractions; and the vomited matter consists of food and mucus. The abdomen is painful; and the dysentery at last becomes colliquative. The urine is yellow, acid, and albuminous. *Post-mortem* examination only shows diastole of the heart and fatty degeneration of the cortical portion, with hyperæmia of the kidneys. Spectroscopic examination of the blood indicates diminution of its oxidizing and nutrient powers. Berberin reduces the temperature, not through the intervention of the vaso-motor nerves, but by its direct action on the tissues, through which action it also indirectly modifies the blood. With regard to the action of berberin on the spleen, Dr. Curci has found that its administration to animals is followed by an enlargement of that organ. Hence he concludes that, in cases where an enlarged spleen has become reduced under the use of berberin,

this has not been due to contraction of the capsule of the spleen, but to the destruction of the malarial miasmatic agent, which is atrophied by berberin in the same way as other histological elements. Dr. Curci concludes from his experiments that berberin may be found useful: 1, in microscopy, as a means of colouring tissues and rendering them resistant; 2, in the treatment of atonic gastro-intestinal catarrh, of chronic dysentery, of wounds and ulcers (in which it does not cause suppuration, and stimulates the activity of the tissues), and of chronic conjunctivitis. Its action on the splenic enlargement of malaria is doubtful, and requires to be studied; and it would appear to be an excellent antipyretic, and to be a remedy against the decomposition of hæmoglobin.—*London Med. Record*, Oct. 15, 1881.

—

Influence of Anæsthetics on the Heart, and on the Antagonism of Poisons.

Dr. RINGER has recently published two papers (*Practitioner*, June and July, 1881) which throw considerable light on the action of anæsthetics on the heart, and incidentally on the vexed question of antagonism. The observations were made with Roy's apparatus, a description of which will be found in Dr. Roy's paper "On the Influences which Modify the Work of the Heart" (*Journ. of Physiol.*, vol. i. p. 452). Considerable difficulties have hitherto been experienced in working this apparatus, arising chiefly from the inconvenience of having to obtain fresh blood for each experiment.

Dr. Ringer finds that the desiccated defibrinated bullock's blood, imported by Parke, Davis & Co., of Detroit, Michigan, answers the purpose admirably. It can be readily obtained, as it is frequently used for enemata in cases of gastric ulcer, etc. For physiological purposes it is dissolved in distilled water, and then diluted with saline, one part of blood-mixture being used to two of salt solution. In each experiment three ounces were used, the same blood being employed in the same series of observations, so that the poison and its antidote were intermixed.

Chloroform acts powerfully on the ventricle of the frog's heart. Like lactic acid, muscarin, and jaborandi, it lessens both the height and duration of the trace until, finally, the heart is arrested in diastole. In one experiment, a minim of chloroform nearly stopped the ventricle; and, when the heart had almost ceased beating, the addition of two ten-minim doses of strong solution of ammonia at once restored its action, until the contractions became almost as powerful as at first. The additions of ten drops of chloroform again stopped the heart. This shows the powerful paralyzing effect of chloroform, and demonstrates most conclusively the mutual antagonism existing between chloroform and ammonia.

It is clear that chloroform does not arrest the ventricle by stimulating the inhibitory apparatus, for the portion of the heart employed contains no inhibitory nerves. Chloroform clearly paralyzes the muscular substance of the heart, for it is well known that the muscular tissue will beat rhythmically without the presence of nervous ganglia. It is evident, therefore, that, did the chloroform paralyze only the ganglia of the ventricle, the ventricle itself would still continue to beat. Further experiments made with the lower half only of the ventricle render this certain, the ganglionless and nerveless portion being affected in exactly the same way as the whole ventricle.

Atropia does not antagonize the action of chloroform on the ventricle; nor will the previous addition of atropia prevent the action of the chloroform. Ethidene-dichloride affects the ventricle in exactly the same way as chloroform. Ether affects the heart in a far less degree than either chloroform or ethidene dichloride. Large doses accelerate the heart's action, and make each beat a

little weaker; but the amount of work done is considerably greater, the increased frequency more than compensating for the diminished force of each contraction. Ammonia and ether, like chloroform and ammonia, are mutually antagonistic as regards the whole ventricle. Bromide of ethyl arrests the ventricle, acting on the muscular substance. It is far less powerful than chloroform, but more poisonous than ether.

Iodoform and ammonia are mutually antagonistic, as shown by their action on the ventricle. A fifth of a grain of iodoform nearly stopped the heart, and then ten minims of a one per cent. solution of strong ammonia restored the contractions, which were again arrested by another dose of iodoform. This was repeated on the same heart three successive times.

The importance of these observations cannot be over-estimated, throwing as they do a new light on the whole subject of antagonisms. ROSSBACH (Pfluger's *Archiv*, Band xxi. Heft 1, p. 1, 1879) contends that drugs are never mutually antagonistic. He maintains that, when a tissue is paralyzed by one poison, it is impossible to stimulate it by another. For instance, whilst atropia, he says antagonizes pilocarpine, pilocarpine cannot antagonize atropia; atropia paralyzes the sweat-apparatus, and pilocarpine is no longer able to stimulate it into action. He admits that after small doses of atropia pilocarpine can produce sweating, and this he explains by assuming that atropia paralyzes first the nerve of the sweat-gland, and later the gland-apparatus itself. After a small dose of atropia the nerve only is paralyzed, and then the pilocarpine can still stimulate the glandular cells; but a large dose of atropia paralyzes the cells also, and then pilocarpine is powerless.

Dr. Ringer's recent experiments demonstrate the fallacy of this argument. The lower half of the ventricle consists of only one substance, muscular tissue, so that the antagonism cannot be due to an action on different structures.—*London Medical Record*, Oct. 15, 1881.

Action and Use of Citrate of Caffein as a Diuretic.

Dr. DAVID BRAKENRIDGE (*Edin. Med. Journ.*, August, 1881) makes the following remarks respecting the action of citrate of caffein as a diuretic. 1. It fails to produce any increase in the amount of the urine in cases in which the renal epithelial cells are diseased—as, *e. g.*, in the early stages of desquamative nephritis —even when vascular and saline diuretics produce a considerable increase. 2. It fails to do so in cases of cardiac dropsy in which, from physiological conditions, we may conclude that the glandular epithelial cells are already doing a maximum amount of work, or are exhausted by transference of work to them from the filtering apparatus. 3. When it acts as a diuretic it increases not only the amount of water passed, but also the amount of urea very markedly, if it have previously been abnormally lowered. 4. Its action is strikingly complementary of that of digitalis; so that, in cases in which both given alone have failed, the two administered together, according to the view suggested, have produced very striking diuretic results. 5. This increase in the amount of the urine may be independent of any increase in the general arterial blood-pressure, sufficient to account for it on any theory of general or local blood-pressure. 6. The combination of digitalis with citrate of caffein causes a striking rise in the amount and percentage of urea, which cannot be explained on any filtration hypothesis. How citrate of caffein stimulates the renal glandular epithelial cells, is still a matter of conjecture. Probably its action is similar to that of jaborandi or pilocarpin on the salivary and sweat glands. In a future paper he hopes to show that the latter substances have a diuretic action like that of caffein. On the other hand, caffein has been observed in exceptional cases to cause both sweating and salivation.

From the foregoing considerations and his whole experience of this drug, Dr. Brakenridge deduces the following practical conclusions regarding the employment of citrate of caffein as a diuretic. 1. In cases in which the renal glandular epithelium is diseased, is already doing a maximum amount of work, or is exhausted, this drug is unsuitable and should not be administered. 2. During recovery from acute desquamative nephritis, when renewal of the renal epithelium has reached a certain point, citrate of caffein, cautiously administered, has appeared to him to have had a decidedly beneficial effect; possibly in such cases it may exert a trophic as well as a secretory stimulant influence. 3. In cases in which the arterial blood-pressure is tolerably normal, citrate of caffein should be given alone, not in combination with a vascular diuretic. 4. In cases of cardiac disease, with absence of compensation, and resulting diminution in the blood-pressure and flow of blood through the kidney, general dropsy, and transference of work in the kidney, from the filtering to the secreting structures, a vascular diuretic, such as digitalis, must be employed in the first place to restore those conditions in the kidney which are essential to the action of citrate of caffein. For this purpose digitalis should be administered for a short period, one to three or four days, before commencing the citrate of caffein. 5. Citrate of caffein, employed in this manner, in conjunction with digitalis, which for obvious reasons, must not be discontinued when the caffein is commenced, is a diuretic of extraordinary power, acts with great rapidity, and is especially valuable in this respect, that it causes a great increase in the elimination of urea (and probably of other solids) as well as of water. 6. It must, however, be remembered that special and powerful stimulation of any gland, especially if it be in a state of malnutrition, may, and usually does, lead, sooner or later, to exhaustion, and must, therefore, be regarded as at best a temporary expedient and of limited duration. 7. For this reason very large doses of citrate of caffein should be avoided. He has found three grains administered once, twice, or three times daily, according to the circumstances of the cases, amply sufficient for all purposes. 8. Whenever the beneficial effects of the drug have been attained, we should at once endeavour to render them permanent by suitable diet, well selected chalybeate and other tonic remedies, or other remedial measures indicated by the special circumstances of the case. 2. Finally, in cases of very great ascites, in which the blood-pressure in, and the flow of urine through, the kidneys is interfered with by pressure on the kidney and the renal artery and vein, and in which the pressure of the urine within the capsules is increased by pressure on the ureters, neither vascular nor secretory diuretics, alone or combined, can act efficiently until the pressure of the ascitic fluid has been got rid of. 10. The citrate of caffein may be administered either in pill or in solution.—*Lond. Med. Record*, Oct. 15, 1881.

Papaya and Papain.

In one of the sessions of the Academy of Sciences in Paris, in August last (*Berliner Klinische Wochenschrift*, Aug. 1881), M. BOUCHUT made some communications regarding the sap of a plant growing in Brasilia, whose botanical name is Carica Papaya, which, according to investigations made by him, with the assistance of Professor Wurtz, possesses distinct digestive and peptonifacient properties. The sap, which is obtained by incisions made into the bark of the plant, and still more so the essential principle prepared from the same, which has been named papain, if for a certain time left in contact with albuminates, raw meat, fibrin, glue, milk, etc., will enter upon combinations which present all the characteristics of assimilable peptone. Croupous membranes, ascarides, tapeworm, were changed in a similar manner, even outside the body.

The statements made at that time Bouchut recently revised and enlarged, reporting experiments, which show that this vegetable pepsin exercises its digestive power even upon living tissues. One gramme of a ten per cent. solution of papain, or one gramme of a solution of the sap, in the proportion of 1.5, injected into the brain of an animal, with a Pravaz syringe, proved to have effected a complete peptonic change in the tissue twenty-four hours after the operation. Upon living muscular tissue the same material injected acted in such a manner that, twenty-four hours after, a soft, pulpous, and gelatinous substance is found in the injected locality. Further injections of the same kind were made upon the cervical glands. After three days, which were characterized by great pain and high fever, the injected glands were found to be softened and turned into abscesses, which could be lanced and emptied of their contents.

In one case of cancer of the breast, and in another of scirrhus of the inguinal glands, in the clinic of Professor Pean, in the Hospital St. Louis, softening and disintegration of the diseased parts was induced by treatment with papain. Some of the fluid contained in the softened growth was afterwards subjected to chemical analysis in the chemical laboratory of the medical faculty, by Professor Henning, and proved to be pure peptone with all its characteristics. According to one of the investigations, 47 grammes of the fluid contain 2.91 grammes of albumen, which again contained 0.565 of peptone after being dried at a temperature of 110°. The same result was reached by other investigations, and confirmed by all chemical tests. All the cases like those formerly mentioned were accompanied by great pain and high violent fever.

In conclusion, Bouchut reports an experiment on a living frog. The animal was partially stripped of its integuments, and then completely dipped in a papain solution. After twelve hours, the animal was dead; after twenty-four hours partially digested, and after two days nothing but the skeleton was left.

Vegetable pepsin, consequently, digests living tissue as well as it digests and destroys dead material outside of the body.—*Medical Herald*, Oct. 1881.

Hypodermic Injection of Citrate of Iron.

An abstract of an observation made by Dr. CIARAMELLI on the hypodermic injection of iron is given in *Lo Sperimentale* for July. A patient under his care had anæmia of an extreme degree, the affection having lasted several years. For four months he was treated with good food, exercise, pure air, decoction of cinchona, and preparations of iron, without effect. No iron could be detected in the urine; from which Dr. Ciaramelli concluded that the iron salt did not pass beyond the hepatic circulation, but was eliminated with the bile. He then injected daily from two to three grammes of a solution of one gramme of ammonio-citrate of iron in twenty grammes of distilled water. After thirty days the rose tint returned to the patient's face, all the symptoms of severe anæmia being at the same time relieved. On chemical analysis, iron was found abundantly in the urine. Dr. Ciaramelli says that this one case is not enough to serve as the foundation of general principles, but it indicates a line of therapeutic research which may be of great practical value.—*London Med. Record*, Oct. 15, 1881.

—

Hypodermic Injection of Water in the Treatment of Pain.

In the *Gaceta Medica* of Venezuela, Dr. PONTE relates his experiences in several instances in which he employed water hypodermically for the relief of pain. The first case was that of a boy who was suffering from an attack of intercostal neuralgia, so severe as almost to endanger the life of the patient by inter-

ference with respiration. Not having any morphine with him, the author determined to work upon the imagination of the sufferer by injecting pure cold water over the location of the pain, a procedure which, much to his astonishment, was followed by permanent relief. Impressed with this fact, Dr. Ponte resolved upon further experiments. The next case was one of toothache. In order to eliminate the imaginative element, he informed the patient of the treatment to be employed, for the execution of which permission was rather reluctantly given. An injection practised upon the side of the face nearest to the pain was followed by considerable ardor, but in less than a minute the odontalgia had subsided. Animated with these results, he employed cold water injections in a variety of different pains, always with happy issue, even in cases where morphine had been the drug previously administered. Another patient had been suffering nine years from intense gastro-intestinal neuralgia, which baffled all remedies. The pain came on after meals, and its violence was such as to cause her frequently to faint. When first seen by the writer, she was utterly prostrated. Two injections relieved the pain, and subsequent tonic treatment restored her to perfect health. Several hundred cases have been treated in the manner described, with good results. No explanation is given as to the action of the remedy.—*Med. Record*, Oct. 8, 1881.

Medicine.

On a Peculiar Form of Disease arising from Milk Contamination.

At the meeting of the British Medical Association on August 4th, Mr. R. Beveridge, M.B., reported that on April 4th, an outbreak of a peculiar form of disease occurred at Aberdeen, which, from special circumstances, seemed to be connected with the supply of milk from a particular dairy, on which account the sanitary local authority intervened, and the supply of milk from that dairy was stopped. From inquiries made, it appeared that, out of 112 families supplied with milk from that dairy, 89, comprising 322 individuals, were attacked; in most cases, the majority of the members of the families being affected. The bulk of the cases of the disease were comprised within little more than a week, from the first to the 8th April, a very few having occurred prior to the first-named day, and a few appearing after the last-named, but no new families having been affected after the last date.

Assuming the milk to be the cause, it acted most energetically when used cold and in quantity, and least so when boiled or used in small quantity. The families affected were scattered indiscriminately over the town, and seemed to have nothing in common except the milk. No cases of the same nature occurred in Aberdeen outside the number using this particular milk, and none occurred elsewhere in Scotland. In several of those families who, though using this milk, escaped the disease, peculiar circumstances existed which may have accounted for the immunity they enjoyed. The special symptoms of the disease were a sharp attack of pyrexia occurring quite suddenly, lasting two or three days, and then subsiding, leaving great and often dangerous prostration behind. The attack was generally succeeded, within two or three days, by a second similar one, and in some cases by a succession of attacks, with complete intermissions between them.

The local symptoms, never specially urgent, were slight sore-throat, with a feeling of fulness or swelling there, little being seen on looking into the throat, but a swelling of the deep glands existing at the angle of the jaw. The successive attacks were marked by the involvement of successive glands, on the

same or on opposite sides. In three cases, the disease proved fatal, all these being elderly persons, and in all the immediate cause of death was the extreme prostration following the attack; death occurring in each case after the lapse of about a week, and several days after all the symptoms had subsided. In one case, a *post-mortem* examination was obtained, which revealed no special lesion connected with the disease, or causing death. The dairy-farm referred to was connected with the Old Mill Reformatory, and was situated about two miles from Aberdeen. The byre was well constructed, large, open from end to end, and contained between forty and fifty cows; at one end, at such a height as not to interfere with the cows beside it, was a large water-cistern, composed of concrete, and covered with a loose wooden lid. This cistern contained about three hundred gallons of water, was filled twice in the twenty-four hours, and from it was obtained all the water used in the byre and in the dairy. In that dairy were washed almost all the vessels used for conveying milk to the consumers. All those whose milk-vessels were not washed there escaped. When the place was examined by the sanitary inspector, the position of the cistern was at once objected to, and immediately on that, the arrangement of the water-supply was altered. Before this was done, however, a specimen of the water in the cistern was obtained, and found on analysis to be highly contaminated with organic matter, although the water before entering the cistern was extremely pure.

The following were the conclusions at which the author arrived: 1. The milk obtained from the cows was good, but the milk supplied to the consumers was dangerously contaminated; 2. The contaminated milk was the direct cause of the disease; 3. The water used in the dairy was dangerously contaminated; 4. Various circumstances seemed to show that, besides the washing of the milk-vessels with the contaminated water, there had been an intermixture of the water with the milk; 5. The symptoms seemed to indicate that the disease was produced by a living organic poison introduced into the system by the tonsils and deep lymphatics of the neck. Microscopic examination seemed to show the presence of one particular organism in the water of the cistern, in the milk supplied to consumers, and in the body of the one case where a *post-mortem* examination was obtained; but the investigations on this point are not sufficiently completed to allow of their being stated in detail. The disease differed from local inflammation in the trifling character of the local lesion, compared with the extreme severity of the constitutional symptoms, in the short duration of the attack, in its periodical recurrence at pretty regular intervals, and in the extreme prostration left behind. From diphtheria it differed in the short duration and periodical recurrence, in the absence of any trace of diphtheritic or false membrane, and in its being absolutely non-contagious.—*Brit. Med. Journ.*, Sept. 24, 1881.

Epithelial Necrosis and Diabetic Coma.

The twenty-eighth volume of the *Deutsches Archiv für Klinische Medicin* contains an article by Prof. EBSTEIN, of Göttingen, on necrosis of the epithelium of the glands in diabetes mellitus, considered with special reference to diabetic coma. He holds that there is not sufficient reason for regarding the presence of acetone in the blood as a *sine quâ non* condition of coma; although he admits its presence in a certain number of cases, and allows that there may be some connection between it and the symptoms observed.

Having already directed attention to the occurrence of necrosis of the renal epithelium in diabetes (von Ziemssen's *Pathologie und Therapie*, Band ix., 1878), he now expresses his conviction, founded on the observation of a considerable number of cases, that this degeneration plays a prominent part in the etiology of

diabetic coma. It is analogous to the necrotic processes occurring in other organs in diabetes, and is met with in two different conditions: 1, in cases where the patient dies with symptoms of diabetic coma, but no coarse anatomical cause of death can be found; 2, in cases where other serious organic changes are found along with the epithelial necrosis. These organic changes—as in acute pneumonia, interstitial hepatitis, and nephritis—may be sufficient to account for death; but still the fatal result may, in the author's opinion, be attributed in some of the cases to the necrosis of the glandular epithelium. This necrosis occurs especially in the kidney, but is also met with in other glands.

In the kidney, the necrosis may affect greater or lesser portions of the organ. In one case, where the patient died of pneumonia, the whole of the epithelium of the cortical portion of the kidney was affected. The necrosis is generally accompanied by an advanced degree of fatty degeneration of the renal epithelium.

On minute examination, the protoplasm is seen to be separated in many places from the tunica propria of the urinary tubules, and to be heaped up in balls and lumps of various sizes, in which the epithelial cells can often be distinctly seen. The epithelium presents either very indistinct nuclei, or none, not even capable of being rendered visible by colouring matter. Along with the dead epithelium, the protoplasm is transferred into simple or fatty detritus. Dr. Ebstein calls the condition of the epithelium necrotic, because it corresponds perfectly to what is met with in other circumstances, where the epithelium is indisputably dead; such as the necrosis of the renal epithelium from ischæmia following infarction or ligation of the renal arteries, or that produced by some poisons, such as the salts of chromic acid.

The necrosis of the glandular epithelium in diabetes is due, in Dr. Ebstein's opinion, much less to anæmia or ischæmia of the organ affected, than to the influence of toxic materials. That the kidneys are most affected, is due to their being the principal emunctories of such matters. In diabetes, these substances are plainly various results of the interference with tissue-change. As far as our knowledge extends, we have to take the following factors into account: 1, the abnormal oscillations of the watery contents of the organism which is the subject of diabetes mellitus; 2, the abundance of sugar in the juices and organs (hyperglycæmia); 3, various substances which appear to be present in abnormal quantities in the blood of diabetic patients, such as acetone, acetic ether, alcohol, etc., as well as oxalic acid; 4, a number of imperfectly known nitrogenous products of decomposition.

The necrotic process in the renal epithelium is of especial importance, inasmuch as it may sometimes produce a sudden arrest of the elimination of toxic substances. Epithelial necrosis thus fills an important gap in the explanation of the sudden occurrence of comatose symptoms in diabetes.

A test of the presence of at least a portion of the products of retrogressive tissue-change, especially those allied to acetic acid, is afforded by the behaviour of diabetic urine with chloride of iron (Gerhardt's test), and by the odour of acetone which the patient exhales. It sometimes happens, in cases where, under the use of a diabetic diet, there is a diminution of the polyuria and glycosuria, that an outbreak of coma occurs, the urine giving the usual reaction with chloride of iron; while in other cases, where the same reaction occurs and the same diet is used, the diabetic symptoms subside, and the patients are better for a certain time. This apparent contradiction is explained by Dr. Ebstein in the following manner. In the cases of the first category, the kidneys retain the power, with the aid of a large amount of urinary water, of completely washing away the products of decomposition, although the necrosed epithelium is no longer capable, when the excretion of water is reduced, of eliminating the waste materials from

the body. In such cases, indeed, the comatose symptoms are often seen to disappear when the patient returns to his ordinary diet and drinks abundantly of water, so as to cause a return of the polyuria and glycosuria. In cases of the second category, the renal epithelium is still capable of performing its function, even when the amount of water excreted is diminished.

Necrosis of the glandular epithelium is not confined to the kidneys. Dr. Ebstein has found an analogous change in the cells of the liver in two cases. In one case, there was no interstitial change; in the other, there was interstitial hepatitis, accompanying diabetes mellitus—a combination which he has also observed in two other cases.—*Brit. Med. Journal*, Oct. 22, 1881.

—

Treatment of Neuralgia and Rheumatism by Electricity and Iodoform.

Dr. Mosso describes, in the *Gaz. Med. di Torino*, 1881, eighteen cases of rheumatism and neuralgia treated by electricity and iodoform. He says that useful effects are often produced by a simple Gaiffe's apparatus, with a weak induced current, in neuralgia and rheumatism. Sometimes, however, the malady does not yield to electricity; and in such cases he has given iodoform internally with success, sometimes alone, sometimes in combination with quinine, salicylate of soda, or bicarbonate of soda. This treatment gave the best result in neuralgia, but was useless in two cases of traumatic sciatica. The daily quantity was from 5 to 6 decigrammes (about 7¾ to 9 grains), besides what was applied externally; and no inconvenience was produced. In one case in which pure iodoform was applied externally, recovery took place, and iodine was detected in the urine. Dr. Mosso says that iodoform may be given without fear in doses of from 10 to 15 centigrammes several times a day, external friction and other means of promoting the action of the remedy being employed at the same time.—*London Med. Record*, Oct. 15, 1881.

—

Cerebral Symptoms in Dyspepsia.

M. LEVEN has reported in *Le Progrès Médicale*, May 28, 1881, one hundred cases which tend to show the existence of cerebral phenomenon whose presence has been heretofore overlooked in dyspepsia. Thus he has seen patients suddenly struck down in the street with true apoplectic attacks which last from ten minutes to a quarter of an hour. Such cases were believed to be epileptic, but M. Leven suggests that they were in reality simply dyspeptic, since the cerebral symptoms entirely disappeared when the digestive troubles had been cured. In dyspepsia the intelligence is unaffected, and there is never any mental disorder. Certain cerebral faculties may be altered, but the *ego* remains intact. This affection of the higher faculties, this weakening of the will, of action, of memory, and of the power of speech, may be readily observed. In some cases the patients are unable to determine upon an act, and they have to make a decided effort to perform what is generally an almost instinctive movement, as for instance to pick up anything that they have just dropped. In such cases the memory is impaired and speech is difficult, more especially after meals. The patients are melancholy, and suffer from cutaneous hyperæsthesia, a point which distinguishes them from the hysterical.—*Practitioner*, Oct. 1881.

—

A Case of Destruction of the Corpus Striatum without Symptoms.

In the *Deutsche Zeitschrift für Klinische Medizin*, xxvii. p. 520, HONEGGER narrates the case of a patient aged 56, who had formerly suffered with rheumatism, was admitted to treatment for various symptoms, such as pain in the abdo-

men, headache, etc. The examination showed chronic nephritis, endarteritis, and hypertrophy of the heart to be present. The patient was not paralyzed in any part of his body, and denied ever having been so. He died of marasmus, and upon post-mortem the following condition was found: In the left corpus striatum a focus of softening extended in to some depth, a similar focus in the thalamus of the size of a lentil, and one of the same size in the upper part of the lenticular body. The whole section of the nucleus candatus, the upper part of the lenticular body and the part of the internal capsule between them were completely destroyed. The centrum ovale was affected for a distance of two cm. around the focus.—*Pacific Medical and Surgical Journal*, Oct., 1881.

Left-sided Convulsions followed by Paralysis.

M. D. MACLEOD, M.B. ED., reports the following case in which unilateral convulsions were followed by paralysis and in which an area of local cerebral softening was found after death.

A. A——, aged seventy-three, female, widow, admitted Aug. 9th, 1879, was reported to have had some "fits" about eighteen months before, but no accurate history could be obtained of her case. On admission she was found to be far advanced in senile dementia. She had no idea of her surroundings, nor could she express herself intelligibly. She was very feeble, and could hardly stand, but was able to move her limbs. She could see fairly well, but was deaf. Her lungs, heart, and kidneys were healthy enough. She had a good appetite. Owing to her feeble state she was mostly confined to bed, where she lay quietly. She continued without much change for a year or so, when it was noticed that she did not see so well. Her blindness increased, and, as far as could be judged, was total for months before she died. She had an attack of convulsions at the end of 1880, but it did not last many minutes. On the 19th of April, 1881, she was seized with clonic convulsions confined to her left side. The left side of her face was throughout convulsed; the left eye was spasmodically drawn outwards; her left arm, leg, and the muscles of the left side generally were in a constant state of spasm; the chin was drawn upwards and to the right. The convulsions commenced about 9 P. M., ceased after a short time, commenced again, and continued, but gradually getting weaker, till next morning. On the 20th the convulsions had entirely ceased, and it was seen that she was completely paralyzed along the left side. Her mouth was drawn to the right, her left cheek flapping, and her arm and leg flaccid and powerless. She was unconscious, and continued in a state of coma till 5 P. M. on the 21st, when she died.

The following were the morbid appearances seen in the brain. It is of interest to note, in connection with the blindness in this case, the complete destruction of the angular gyrus of the right hemisphere. The general diseased state of the vessels of the brain, the great atrophy, and the extent of the softening, render a localization of the lesion causing the convulsion difficult; but it is noteworthy that the disease was of the motor area and the tracts connected with it.

Post-mortem appearances.—Head: The scalp was normal; the calvaria was thick, soft, spongy. The dura mater was thickened and tough; the sinuses were full of black clot. On cutting into the dura mater 8 oz. to 10 oz. of cerebro-spinal fluid escaped. The arachnoid was opaque; the vessels of the membranes generally were full of blood. The pia mater was thick and œdematous; it was easily separable from the convolutions except at a spot over the right postero-parietal region, where there was some gelatinous effusion. The arteries of the brain were very atheromatous, markedly so the right middle cerebral; the basilar artery was comparatively healthy. The brain was small (weight 32½ oz.; right

hemisphere 14½ oz., left hemisphere 14 oz., cerebellum and pons 4 oz.). The convolutions were atrophied generally; they were small and much divided by shallow sulci. The cranial nerves were atrophied; the optic nerves, chiasma, and tracts were small and flattened; there was apparently no local atrophy or disease of the right hemisphere. The convolutions of the left hemisphere were small throughout. There was an area of old yellow softening in the left postero-parietal region; this area included the angular gyrus, the posterior portion of the supramarginal gyrus, a small part of the superior parietal lobule just anterior to the parieto-occipital fissure, the upper margin of the first temporal and a very limited portion of the second occipital convolutions. The whole gray matter of this softened area was destroyed, as was the white matter underneath. A band of softening extended inwards and forwards to the posterior part of the thalamus opticus, into which the left optic tract entered, and another line of yellow softening anterior to the other, and separated from it by apparently healthy white substance, was easily traceable to the corpus striatum, the posterior part of which was softened. There was no apparent softening or degeneration in the crura, the medulla, or pons. The convolutional softening corresponded to the area supplied by the branch of the middle cerebral artery running in the horizontal ramus of the Sylvian fissure. This vessel was markedly atheromatous and diminished in calibre. The branch ascending was free of atheroma; the lateral ventricles were dilated; there were gliomatous bodies on the choroid plexus; the cerebellum and pons were soft; the other organs of the body presented no marked abnormality.—*Lancet*, Sept. 17, 1881.

—

Spinal Lesions from Compressed Air.

The paraplegia which has occasionally been observed in professional divers has been ascribed by M. PAUL BERT to the effect of the compressed air, and he has reproduced it experimentally by subjecting animals to air compressed to seven or eight atmospheres in special apparatus. MM. Blanchard and Regnard have endeavoured to complete these researches by studying the changes in the spinal cord produced by this influence. Some animals (dogs) died soon after the restoration to normal conditions; others lived several days. One of these was attacked with paraplegia, but recovered perfectly. It was ultimately killed, and the spinal cord was found to present numerous foci of hemorrhage and evidence of acute parenchymatous myelitis. There was no sclerosis. The minute hemorrhages existed not only in the gray substance, but were met with in the entire length of the cord; sometimes in the anterior, sometimes in the posterior cornua. The myelitis had the usual characters; hypertrophy and varicosity of the axis-cylinders, and granular masses scattered through the tissue. The change occupied various situations in the white substance, and was in some places of considerable extent. It was least in the lumbar enlargement and was most intense in the dorsal region, where it was so extensive that the recovery of function is difficult to understand.—*Lancet*, Sept. 17, 1881.

—

Nerve-Stretching in Diseases of the Spinal Cord.

Dr. CARL LANGENBUCH has published, in Nos. 24, 25, 26, and 27 of the *Berl. Klin. Woch.*, his further experiences of the results of nerve-stretching in tabes and other diseases of the spinal cord. He shows that, on account of the long course of tabes, the later stages alone are seen in the post-mortem room, and he also points out that in this disease there are lesions of nerves, as well as of the cord. Sometimes congestion of the nerves, sometimes anæmia, is found. In answer to the question, "Why are the posterior root-zones affected?" he an-

swers that these are the media of communication between centre and periphery, and may be regarded as practically peripheral substance. The columns of Goll connect gray centres with one another, and are only secondarily affected. He regards cold as the great cause of tabes dorsalis.

With regard to the treatment of this and similar diseases, the author observes that even the most useful means—baths, electricity, cautery, etc.—produce only small benefit occasionally; much improvement rarely; recovery never. Such methods act on the end-organs, and thence affect the centres. Nerve-stretching acts directly on the centre; and, although brought forward with caution, it has been abundantly successful. If necrosis of nervous elements have set in, the cure is only partial; but if the disease be taken early, the recovery is complete. Of twenty-eight patients, sixteen suffered from tabes, two from multiple sclerosis, one from lateral sclerosis of both sides, one from lateral sclerosis of one side, one from muscular atrophy, two from tetanus, three from spinal myelo-meningitis, one from pemphigus, and one from pruritus. Six of the tabetic patients were dismissed as cured; the others were recent, and were still in bed when the paper was published. The multiple sclerosis was much relieved in both cases. The one-sided lateral sclerosis was entirely cured, and the bilateral case was too recent to be set down in the list of recoveries. The case of muscular atrophy was considerably improved, but was only recently operated on. The tremors were much diminished, but sufficient time had not elapsed for certainty to be attained. Two cases of myelo-meningitis had only just been treated, and the effect was uncertain; in the third there was little, if any, improvement. Both cases of tetanus died; and, lastly, the case of pemphigus and that of pruritus were both entirely cured. During the operation both pulse and respiration undergo considerable but varying changes, and when much alteration was observed, further stretching was not allowed. After the influence of the anæsthetic had passed off the patients had no uneasiness, and expressed themselves, in certain cases, as grateful for the removal of pain. Sensibility was never diminished, but sometimes increased, and there was total removal of the feeling of cold in the extremities. In some cases the one leg felt as if longer than the other, and there was a sensation of being in a strange position. Motility was rapidly restored, and the ataxy removed. Constipation ceased, and involuntary micturition was cured in some cases; and in one case impotence was brought to an end. The sight was improved in cases where it had been affected. The after-results of longer periods have necessarily not been observed as yet; but we have sufficient evidence to lead us to hope for much.

Dr. Langenbuch shows that nerve-stretching has an influence upon the whole nervous system, and in conclusion points out that, in disease of the spinal cord, nerve-stretching is a method of treatment from which, under antiseptic management, nothing is to be feared, and everything may be gained.—*London Med. Record*, Oct. 15, 1881.

—

Ergot in the Paralysis of Lead Poisoning.

According to Dr. J. A. STITES, in the State of Nevada it may be safely estimated that fifty per cent. of the physician's practice consists of cases of lead-poisoning, the symptoms being in most instances well marked, while in the remainder they are more or less masked. Of the remaining fifty per cent. of practice, the bulk is furnished by accidents and syphilis. The occupation of the male population is mining in silver ore, which is largely associated with lead. Wrist drop is a very frequent symptom, and paralysis of other forms, even hemiplegia and paraplegia, is not an infrequent complication. In the milder mani-

festations of these symptoms, a cathartic of sulphate of magnesia, followed by iodide of potassium, usually removes them in a few days, enabling the sufferer to resume his work. The habits of the miner render him peculiarly susceptible to attack, and Dr. Stites has found that when his patients abstain from alcoholic stimulants, keep their bowels open, and preserve their appetite by proper living, they are much less apt to suffer from lead-poisoning.

In hemiplegia and paraplegia due to lead-poisoning, Dr. Stites has found ergot in combination with iodide of potassium and nux vomica to expedite recovery. He has tested its efficacy by comparison in the hospital with which he is connected, adopting three varieties of treatment: (1) iodide of potassium alone; (2) electricity with tonics and nux vomica; (3) iodide of potassium and ergot. The latter plan has been attended with the utmost satisfactory results. The following is his standard prescription: ℞. Potassii iodidi, ʒij; ext. ergotæ fluidi, ℥j; ext. nucis vomicæ fluidi, ʒj; tr. cardamomi co., ℥j; syrupi, q. s. ad ℥iv. Misce. Sig.—A tablespoonful night and morning.

Usually in a month the power has been restored to the paralyzed parts. Under other forms of treatment recovery does not usually come under three months. The efficacy of ergot is attributed to the well-known physiological action of ergot on the non-striated muscular fibre. The dangers which were formerly supposed to be attendant on the prolonged employment of ergot, such as gangrene, etc., are certainly not to be apprehended, according to the author, in the therapeutic employment of the drug.—*Therapeutic Gazette*, Oct. 1881.

—

Treatment of Empyema.

Dr. W. Wagner of Königshütte, in commenting on a case of empyema successfully treated by operation under antiseptic conditions (*Sammlung Klinische Vorträge*, No. 197), states that the treatment of this affection has now reached a fresh stage; and that, since the introduction of Listerism, an operation, instead of being a mere palliative measure, is to be regarded as justifiable under all circumstances, and, in cases of simple empyema at least, as free from risk.

The surest way, Wagner asserts, of distinguishing an empyema from a simple pleuritic exudation, is to make an exploratory puncture. This may be done with a disinfected hypodermic syringe and trocar, or, better still, with a larger syringe, such as that used by veterinary surgeons, which holds about five grammes of fluid, and is furnished with a strong and large needle. The exploratory puncture, however, does not always guard against errors in diagnosis. In the first place, a case may be met with in which there are two separate and distinct exudations, one a serous, the other a purulent exudation. Then, again, it may happen, especially in cases of exudation originally serous or sero-purulent, that have become purulent, that the exploratory puncture will give vent to serous fluid in the upper part of the collection and to purulent fluid below. In a patient lying constantly on his back, this precipitation will take place not to the inferior but to the posterior part of the thoracic cavity, so that serum will be present in front and pus behind. Dr. Wagner, though acknowledging that cases of this kind are rare, lays it down as a rule that, in every case of pleural exudation in which the general symptoms indicate empyema, several exploratory punctures should be made at different parts of the corresponding thoracic wall, should it happen that at the first or earlier punctures serum and not purulent fluid is withdrawn.

At the present day, no medical man believes in the possibility of the absorption of a purulent pleural exudation. The so-called "natural cure," in which the pus is discharged through the air-passages, is of rare occurrence, and, when

it does occur, is likely to have bad results, and to give rise to phthisis through the contact of the discharge with the lung-tissue, or through its aspiration into the fine bronchial divisions. Spontaneous discharge of an empyema through the thoracic wall cannot be regarded as a favourable termination, as it is often followed by an obstinate fistula.

In a case of well-marked empyema there is, in Wagner's opinion, an almost unconditional indication to operate at as early a date as possible. Unless the affected pleura covering the lung be soft and yielding, and the lung itself be capable of complete re-expansion, the chances of a speedy and good cure will not be favourable. An acute pneumonic infiltration still persisting, whether to a high or low degree, should not prevent early recourse to operative treatment, for with removal of the empyema the pressure on the lung is removed. This organ is thus set free, and as its normal conditions of circulation become re-established, the absorption of the inflammatory exudation is favoured. If the inner wall of the abscess be stiff and unyielding in consequence of thickening of the pulmonary pleura, then cure cannot be effected speedily, and cannot possibly occur at all, unless the resistance of the thoracic wall or that of the tough pulmonary pleura can be overcome. Wagner sums up his remarks on this subject by stating that, when we operate in the early stage of empyema, we meet with the most favorable conditions for the re-expansion of the lung and for the approximation of the walls of the abscess. The older such an abscess, the thicker will be its walls, and the greater difficulty will there be in the obliteration of its cavity. In the application of the above rule, it is, of course, to be understood that the operation be performed under antiseptic conditions. Dr. Wagner is not in favour of treating empyema by simple puncture and aspiration. Such treatment may occasionally prove successful, especially with young children, in which class of patients there is likely to be a rapid re-expansion of the lung after removal of the purulent fluid; but it is attended with this disadvantage, that, as it is almost always impossible thus to remove all the pus, there is likely to remain a small quantity of this secretion, the presence of which invariably causes a relapse of the empyema. The rule is laid down by Wagner that it is not justifiable to try puncture more than once in a case of empyema, and that, if this first attempt do not succeed, the surgeon ought, without delay, to have recourse to incision. The longer an empyema is allowed to run its course, the less favourable become the chances of a cutting operation, and with repetition of simple puncture valuable time is lost.

Though an incision through the thoracic wall low down in the back of the chest may be most favourable for a full discharge during the operation, and in the course of the after treatment, yet, Dr. Wagner holds, this situation can hardly be regarded as being under all circumstances the best in the operation for empyema. The inferior and posterior part of the affected pleural cavity is often obliterated in consequence of pleurisy, and the space may be so contracted through approximation of the elevated diaphragm and the inner wall of the thorax, and also through re-expansion of the lung, that free discharge of pus from the pleural sac is prevented. Dr. Wagner prefers an incision in the fifth or sixth intercostal space, near to the edge of the latissimus dorsi muscle; and in order to promote a free discharge during the after-treatment, he keeps his patient lying on the side, with the pelvis and lower part of the trunk elevated on a firm pillow.

In the cutting operation for empyema, Dr. Wagner recommends the administration of an anæsthetic. With anæsthesia, the surgeon is less likely to be disturbed through restlessness of the patient, and he may, if it be found necessary, proceed without delay to resect a portion of rib. Care, however, must be taken that the movements of the chest on the sound side are not impeded during the operation.

Sudden death, which has occurred in some cases of empyema during operation, cannot, it is stated, be attributed to the anæsthetic. It has been due rather to some disturbance of circulation (thrombosis, cerebral anæmia, embolism of the pulmonary capillaries, pulmonary congestion, or œdema). These instances of sudden death have occurred as frequently during simple thoracentesis without anæsthesia, as in cutting operations for empyema.

The details of the cutting operation are very simple. The surgeon either makes an incision through the skin about two inches in length along the upper margin of a rib, and then slowly divides the muscles until he reaches the pleura, which he opens with a small bistoury; or, following König's practice, he resects subperiosteally a portion of rib about one inch in length, and then opens the thoracic cavity by incising the posterior layer of periosteum and the pleura. This latter operation should always be performed when the intercostal space is not of sufficient width to admit of the passage of a wide drainage-tube. It is not likely to be attended with any bad result, and in young subjects the resected portion of rib is almost always wholly replaced.

During the flow of pus, which should not be allowed to take place too rapidly, the surgeon should carefully examine the fluid, and also introduce his finger through the opening into the pleural cavity, in order to ascertain the condition of the surrounding wall. He thus endeavours to make out indications for future treatment. If the purulent discharge be free from smell, and do not contain flakes, no injection need be made into the sac; but if, on the other hand, it be fetid, and be mixed with large and numerous fibrinous masses, then it is necessary to wash out the cavity. Dr. Wagner now uses in such cases a 7 per cent. solution of boracic acid. If the walls of the purulent sac be felt to be thick and rough, and if they be evidently covered by adherent masses of fibrine, then it is necessary to wash out the cavity thoroughly and repeatedly with strong antiseptic solutions, which, in order that chilling may be avoided, should be warmed before they are injected. It is advisable, in dealing with such a condition, to make a second opening into the thoracic cavity.

When the pleural cavity has been opened, relieved of its purulent fluid, and washed out, or, as should always be done in simple cases of pyæmia and with children, has been simply emptied, a piece of drainage-tube of wide calibre, the length of which need not be more than two inches, should be inserted into the wound. Across this tube, near its outer extremity, a needle is thrust. This prevents the tube from falling into the thoracic cavity, whilst two sutures applied to the margins of the external wound and tied around the needle prevent it from being forced outwards. During the operation and immediate dressing, and also during subsequent dressing, Dr. Wagner guards the exposed parts by the carbolic acid spray. The first dressing, by which the whole of the affected side of the chest is covered, and which reaches from the axilla to the pelvis, consists of thick layers of Lister's gauze and of salicylated wadding. The first dressing ought not, it is stated, to be allowed to remain for a longer period than twenty-four hours, even though no secretion has made its way to the surface. The surgeon should then make sure that the drainage-tube remains in position, and that it is patent, and not obstructed by a clot. Retention of pus thus caused is a serious matter in a case of simple empyema, since a continuous and full discharge of the secretion is a necessary condition of a speedy cure. For the same reason, it is held advisable to change the second dressing after a short interval. The thermometer is a sure indicator of retention of pus, but not until this has been established for some hours. During each change of dressing, which, as has been stated, is always done in Dr. Wagner's practice under the spray, the drainage-tube should be removed and thoroughly cleansed, and, if necessary, be shortened before it is

replaced. If, during the after-treatment of a primarily simple case of empyema, the pus become fetid and mixed with flakes and shreds of fibrine, the pleural cavity at each change of dressing must be washed out with an antiseptic solution. Dr. Wagner recommends a solution (three to eight per cent.) of boracic acid, or a five per cent. solution of chloride of zinc.

Careful observation of temperature is of the highest importance during the after-treatment of empyema. In a case of simple empyema, the temperature, after an antiseptically performed operation, should from the first be almost normal, unless there be any disease of the lungs or other viscera. An evening temperature of over 101 deg. should always arouse a suspicion that the pus does not flow freely, or that it is no longer in a good condition. A persistence of fever may be caused also by the presence within the pleural sac of fibrinous masses, and, in such case, steps should at once be taken to remove these. In many cases of empyema, these masses exist in abundance, and set up fever by acting as foreign bodies and by becoming decomposed. When the purulent fluid discharged at the time of operation is found to contain fibrinous flakes, and the walls of the cavity can be felt to be roughened and covered by similar deposits, the case can only be treated as one of simple empyema, and an attempt must be made to remove all the material. A portion of rib should be resected, in order that the opening in the thoracic wall may be of sufficient size, and the surgeon should then attempt to remove as much as he is able of these fibrinous masses, by introducing his finger and by washing out the cavity. The injected fluid should be an antiseptic one sufficiently concentrated to disinfect, as far as may be possible, any remaining deposits. The use of such injections should be continued until the purulent discharge becomes free from smell, and is no longer mixed with portions of fibrinous material. The further treatment of complicated empyema, so long as the pus is in good condition, is the same as that of simple empyema.

Dr. Wagner warns against replacing too soon during the after-treatment a thick and short drainage-tube by one of smaller calibre. A weak and narrow tube will more readily become obstructed, and offers less resistance to the tendency of the ribs immediately above and below the wound to come together and obstruct the flow of pus. When there has been no secretion for about eight days, and the temperature has remained during this period quite normal, the drainage-tube may be removed The wound generally heals then very rapidly. If in cases of this kind there occur a reaccumulation of pus, the abscess is usually a small one, and its sac is cut off from the pleural cavity. If the discharge do not cease very soon, it would be advisable, Dr. Wagner states, to brush over its lining membrane a strong solution of chloride of zinc. No injection should be made into this abscess, as the recent adhesions might readily be broken down. — *London Med. Record*, Oct. 15, 1881.

Incision of the Pericardium.

Prof. S. ROSENSTEIN reports the following case in the *Berliner Klinische Wochenschrift*, 5, 1881. On Jan. 16, he examined a boy ten years old. Two weeks before he was taken sick with fever and with gastric symptoms, and since that time he had been short of breath and had a little cough. Careful examination revealed the presence of a very considerable pericardial exudation. Change from lying to sitting made no change in the form or extent of the area of dulness. The boy had no fever, the skin of the thorax was not œdematous. An exploratory puncture with a hypodermic syringe showed pus. The increase of the dyspnœa led Rosenstein to perform puncture with aspiration, by means of which 620 ccm. of purely purulent fluid were withdrawn with the result of immediate and complete euphoria. But on the very next day the pericardial exudation increased,

and a left pleuritis developed, so that two days later 1200 ccm. of pleuritic and, again, 120 ccm. of pericardial exudation were removed with the aspirator. The general condition of the patient now growing worse, it was decided, on the eleventh day after admission, to incise the pericardium under antiseptic precautions. This was done, two drains were introduced, and Lister's bandage applied. A magical improvement of the general condition began. Nineteen days after the incision the boy was well, so far as the pericardium was concerned. The pleuritis having meantime become purulent, an incision of the pleura was necessary, but this also healed completely after some weeks. Rosenstein remarks that the case teaches: 1. That purulent pericarditis, like empyema, may run its course without any fever or any œdema of the skin, so that it can only be recognized by exploratory puncture. 2. The fear of myocarditic changes should not hold us back from removing the exudation in suitable cases, because all the symptoms which make such probable can be explained by functional changes in the elasticity and contractility of the heart-muscles. 3. When there is a large collection of fluid in the pericardium, change of the patient's position may have no influence on the height of the area of dulness, so that this criterion cannot be relied upon in differentiating from dilatation of the heart.—*Amer. Journ. of Obstetrics*, Oct. 1881.

Severe Chronic Gastric Catarrh treated by Washing out the Stomach.

Professor RIVA relates, in the *Rivista Ital. di Terapia ed Igiene*, 1881, the case of a man who had suffered for eleven years from gastric catarrh, the disorder becoming steadily worse, until at last he vomited his food mingled with blood. In this condition he was admitted into the hospital at Perugia. He was extremely emaciated, and percussion in the epigastrium showed that the stomach was greatly distended. He suffered while in hospital from extreme weakness, sour eructations, intense thirst, anorexia, vomiting (which was more frequent in the morning than at night), and constipation. The vomited matter was of very offensive odour, frothy and sour; under the microscope it presented digested and undigested fibres of meat, starch-granules, fat-globules, mucus-globules, epithelial cells, and sarcoma. Dr. Riva determined to try the effect of washing out the stomach; and used for the purpose a Nélaton's sound, made rigid by the introduction of a metallic wire; to this was fitted a Kussmaul's pump, and the operation was conducted cautiously, so as not to injure the gastric mucous membrane. The fluid used was a solution of 6 grammes (93 grains) in 1000 grammes (about 35 ounces) of water. After two or three operations, the presence of the tube in the stomach did not cause any attempt at vomiting. As this treatment produced only transient improvement, the quantity of bicarbonate of soda was increased to 10 grammes in 1000 of water. The treatment by bicarbonate of soda having been continued ten days without other marked result than cessation of the vomiting, solution of sulphate of copper (5 grammes in 1000 of water) was injected, and allowed to remain three or four minutes. Under this treatment the patient rapidly improved, and left the hospital a month after admission, having gained 9 kilogrammes (nearly 20 pounds) in weight.—*London Med. Record*, Oct. 15, 1881.

Hydatid Tumour of the Liver in a Young Child.

Hydatid disease of the liver is an affection which attacks young children so infrequently that the following case seems worthy of record.

S. W., a perfectly healthy-looking boy aged four years and a half, came under treatment at the Manchester Southern Hospital on the 22d of September, 1880.

Two days before, while playing with other children, a bigger boy took hold of him round the waist and lifted him from the ground. He ran home crying, and complained of pain about the stomach, and on examining him his mother found a swelling in the abdomen.

When he was admitted to the hospital a bulging prominence was found in the epigastrium, rather to the right of the median line. On palpation a globular tumour could be felt about the size of a small orange; it was smooth, tense, somewhat elastic, but not fluctuating. There was no hydatid fremitus, nor was there any pain or tenderness on pressure. It could be seen and felt to move freely with the respiratory movements. On percussion the dulness over the tumour was found to be continuous with that of the liver. There was no general enlargement of the liver; in the right mammary line it measured two inches, but slightly to the right of the median line (*i. e.* in the line of the tumour) three inches and a quarter. The lower margin of the projection was one inch from the umbilicus. There had been no jaundice or other constitutional symptoms. Owing to unwillingness on the part of the boy's parents nothing was done for two months, during which the swelling increased in size, and approached on the surface. On November 15th it was explored by means of the aspirator and a fine needle, and thirteen drachms of fluid were evacuated. The fluid was perfectly clear; it contained no albumen, but abundance of chlorides, so that, although no echinococci or hooklets could be found under the microscope, there could be no doubt of the hydatid nature of the tumour. There was no urticaria after the tapping, a symptom which is of tolerably frequent occurrence. This sequela has been supposed to be due to an escape of a small quantity of hydatid fluid into the abdominal cavity. If this was the true explanation there certainly ought to have been urticaria in this boy's case. Wishing to insure perfect quiet, chloroform was given, hoping that the small quantity necessary would not be followed by sickness. However, as soon as the needle was withdrawn, violent and repeated retching occurred, so that a drop or two of the fluid could hardly fail to have escaped into the peritoneum. It may be added that in neither of these cases was any blood drawn through the aspirator, as sometimes occurs, on account of the possibility of which event Dr. Murchison advised that the aspirator should not be employed.

In this case the tumour slowly diminished in size, and two months after the aspiration not the slightest fulness could be felt over the region formerly occupied by the cyst.—*Lancet*, Oct. 29, 1881.

—

Filaria Sanguinis Hominis.

Dr. Stephen Mackenzie recently brought before the London Pathological Society a patient suffering from hæmato-chyluria, in which the filaria were found in the living state. This parasite, like so many similar creatures, presents us with an example of alternation of generations; or, more correctly speaking, of the need of two hosts for its full development. The minute almost structureless worms found in the blood of the human subject in such vast numbers are the *embryonic* forms of the filaria which requires the mosquito in which to develop into the sexually mature worm. The mosquito feeding on the blood at night, when the filariæ are generally alone to be found, becomes gorged with them. Their growth in the mosquito has been traced by Lewis and Manson, and it is presumed that they are only liberated from the body of their host by its death in the water to which it always finally resorts. The nematoid is thus set free, and possibly undergoes further development; for the mature worm measures some three inches in length. Its passage into the human body is easily explained; and the analogy

in this respect with the larger nematoid—the guinea-worm—is one which Dr. Vandyke Carter ably illustrated. Once within the human body, the worm lodges in the tissues, but as to its migrations, and, indeed, its ultimate resting-place, but little is known. It would seem, from its discovery in a lymphatic abscess by Bancroft, and in a lymph scrotum by Lewis, to have a peculiar aptitude for selecting the lymph channels for its habitat; a selective power not more remarkable than that which urges the trichina to lodge in muscular tissue. This is further borne out by the fact that its embryos—the filaria sanguinis hominis—are met with in the blood and the urine of the subjects of chyluria and nævoid (or lymphatic) elephantiasis.

Now, although the various discoveries which have been made—at the expense of so much patient research and at such various times that, as Dr. Cobbold remarked at the meeting, they form each distinct "epochs"—have enabled us to form the above complete sketch of the life-history of the parasite, there are lacunæ still to be filled up. Thus knowledge is wanted upon the growth and migration of the parent worm after it has gained entrance into the human body, also as to its duration of life, and particularly as to the question whether it can take on the power of sexual reproduction, and if so, for how long a time. The myriads of filariæ that are probably daily reproduced in the body of such a patient as that under Dr. Mackenzie's care seem to demand such a fact as alternate generations, and also to raise the question as to the time during which the process of reproduction can continue. There is no reason to believe that the embryonic filariæ in the blood can undergo further development within the human body; indeed, analogy, as well as the remarkable discovery of an intermediate host in the mosquito, are opposed to this notion. Again, filariæ have been found in the blood apart from chyluria or any outward manifestation of lymphatic derangement; but this is explicable if it be admitted that the adult worms may lodge in other parts of the body in communication with bloodvessels alone. Conversely, chyluria may exist without filaria, and the case mentioned by Dr. Mackenzie, where the parasite was found in the man's blood in India, but could not be found when he came to England, is explicable on the view that though the parent organism might have perished, or yielded no more embryos, yet the change excited by its presence in the lymphatic channels, and therefore the chyluria, might still have persisted.

The precise mechanism of chyluria still requires to be explained, and until it is elucidated an important part of the subject will remain obscure. The question of the pathology of chyluria was, however, barely touched upon on Tuesday: Dr. Mackenzie limiting himself to the statement of the facts observed in his case; the most important in connection with the urine being that besides having all the chylous characters, it invariably contained more or less blood—that passed by day containing more blood and filaria, that passed by night being more milky; and that filariæ were found in it, especially in connection with blood coagula. The most remarkable feature of the whole case lay in the periodicity shown by the filariæ in their time of appearance in the blood. During the whole period of the man's stay in hospital, the blood had been examined regularly every three hours, with the constant result that, by night, the filariæ abounded and by day were entirely absent. From 9 A. M. to 9 P. M. they were absent; they appeared at the latter hour and increased up to midnight, then decreased till at the first-named hour none were found. These observations entirely confirmed those of Manson, and particular stress was laid upon their nocturnal wanderings and the habits of the mosquito. It is certainly singular that the time selected by the mosquito should coincide with the presence of the parasite in the blood stream, and the connection of these two facts is not the least wonderful chapter in the life-history of the parasite. But whatever the explanation of the periodicity—Dr. Vandyke

Carter pointed out that it was not invariable—a valuable addition to our knowledge of it has been made by Dr. Mackenzie. He found that whereas the time of ingestion of food bears no relation to it, it is otherwise with the time of rest and sleep, for when the patient was up during the night and slept during the day the period of filarial migration was similarly inverted.—*Lancet*, Oct. 22, 1881.

—

Psoriasis from Borax.

Among the cutaneous eruptions which may result from the administration of drugs, psoriasis has not, according to Dr. W. R. GOWERS (*Lancet*, Sept. 24, 1881), been hitherto included. The following facts, which he narrates, show that an eruption of characteristic psoriasis may result from the internal administration of borax. The facts have been met with in the use of borax in the treatment of obstinate cases of epilepsy, in which bromide fails. The first instance was in the case of a man who had taken borax for nearly two years in doses of first fifteen grains and then a scruple three times daily. An eruption of psoriasis made its appearance on his limbs and trunk, developing to a considerable extent in the course of a few weeks. Five minims of arsenical solution were added to each dose of borax, and the eruption rapidly disappeared. Shortly afterwards Dr. Spencer of Clifton, in mentioning to me a case of epilepsy in which he had given borax with advantage, inquired if I had met with any inconvenience from its use. I told him of this case, in which I thought it possible that the psoriasis was produced by the borax, and he informed me that in his patient the same eruption had just appeared. In this case also the rash rapidly cleared away under the influence of arsenic, and a few weeks later Dr. Spencer wrote to me, "I have not the slightest doubt that the borax caused the psoriasis, or that the arsenic cured it." A third instance has lately come under my notice. The patient was a young man who had suffered from epilepsy since infancy, and was always rendered worse by bromide, so that he was brought to me with the request that bromide might on no account be given. He took borax, first fifteen grains and then a scruple three times a day, with greater benefit than had resulted from any previous treatment, and after eight months an eruption of psoriasis appeared. Arsenic was added, but the result of treatment has not yet been ascertained.

The eruption in these cases occurred on the trunk, arms, and legs, but more on the arms than elsewhere. The face was free. It was located on both the flexor and extensor aspects. The patches varied in size, up to an inch and a half in diameter. Their appearance was quite characteristic, but the scales were not so thick as they sometimes are in ordinary psoriasis. In no case was there a history of syphilis, and in Dr. Spencer's patient syphilis could, with certainty, be excluded.

—

Gangrenous Eruption in Connection with Chicken-pox and Vaccination.

At the meeting of the Royal Medical and Chirurgical Society on October 25, Mr. JONATHAN HUTCHINSON narrated the details of a case which had been brought before the society two years ago. A child in perfect health was vaccinated with several others from the arm of a healthy infant. None of the other children suffered. In this child nothing unusual happened to the vaccination-vesicles, which ran their course naturally. On the eighth day after vaccination, however, an eruption came out on the body and limbs, which three days later was diagnosed by the vaccinator as variola. Some of the spots had at this time become dusky, and threatened to slough; and afterwards gangrene attacked large numbers of them. Between the eleventh and the twenty-first days, no

surgeon saw the child. It died on the latter date; and, an inquest having been held, the coroner requested Mr. Hutchinson to examine the body, and to report on the nature of the disease. The body, which on a former occasion was shown to the society, and of which drawings were again produced, was that of a well-grown healthy child. It was covered with gangrenous sores; the sloughs being black, and in many instances extending into the subcutaneous cellular tissue. Some of them were as large as shillings. There were numerous smaller sores on which no gangrene had occurred. The sores were arranged with tolerable symmetry over the scalp, face, trunk, and limbs; but the hands and feet were exempt. A *post-mortem* examination by Dr. Barlow showed no disease of internal organs. The child had died from exhaustion in connection with the extensive affection of the skin. The author stated that, so far as he knew, this was the first example of a gangrenous eruption following immediately upon vaccination; and that he was inclined to regard it as an instance of the vaccinia exanthem running, in connection with idiosyncrasy, an unusual course. Since the case was first brought before the society in November, 1879, another almost similar one had occurred in Dublin, and had been carefully recorded by Mr. William Stokes. By the kindness of Mr. Stokes, drawings representing the condition of his patient were presented to the meeting. In this instance the patches of gangrene, although larger, were fewer in number and more superficial; and the infant, although for a time in great danger, eventually recovered. The two cases were almost exactly parallel, excepting that in Mr. Stokes's case a much shorter interval between the vaccination and the appearance of the eruption was assigned by the mother. There were, however, great doubts as to her accuracy and truthfulness, since the medical man whom she asserted to have vaccinated the baby said that he certainly had not done it on the day that she alleged. The eruptions affected the same parts in the two children. In both the hands and feet were exempt; and in neither did the vaccination-spots themselves become gangrenous. The author next proceeded to another part of the subject—the attempt to demonstrate that chicken-pox does occasionally assume a gangrenous form, and present conditions very similar to those just described in connection with the vaccinia exanthem. He had, he said, for ten years or more been in the habit of recognizing a gangrenous form of varicella, and several patients suffering from it had come under his care at the Moorfields Hospitals with suppurative iritis. In some cases the disease had proved fatal; but in the majority the patient recovered, with deep scars, and sometimes with great damage to the eyes. In the worst cases, the eruption involved the whole thickness of the skin, and left an abruptly margined, punched-out ulcer. The author quoted from a paper published by Dr. Whitley Stokes, of Dublin, in 1807, in which this malady was, he thought, clearly described. Dr. Whitley Stokes said that it was well known in many parts of Ireland under the name of "the white blisters," "the eating hive," and "the burnt holes." Dr. Whitley Stokes had noticed the resemblance of the disease to chicken-pox, but had attempted to diagnose between them, alleging that, in chicken-pox, the fever always preceded the eruption; and that the pustules always dried quickly. The author of the present paper contended that neither of these distinctions would hold good, and drew attention to the fact that Dr. Whitley Stokes had, like himself, observed that the eruption usually occurred in very healthy children; that at its first stage it was like chicken-pox; that severe inflammation of the eyes sometimes occurred; and that the worst cases ended fatally. The final proof upon which the author relied that the eruption was no other than a modification of varicella was, that he had seen it repeatedly occur to one child in a family whilst several others were going through varicella in its ordinary form. For two examples of this, he had recently been indebted to his

friends Dr. Barlow and Dr. David Lees, of the Children's Hospital. Of one of these cases a drawing was shown. The author referred to some wax casts in the Guy's Hospital Museum which, he said, well illustrated the condition which he had been describing. They had been named rupia escharotica; but he could have no hesitation in believing them to be examples of gangrenous varicella. In conclusion, he urged that if the proof were accepted, that, in connection with idiosyncrasy in perfectly healthy children, the eruption of varicella might occasionally assume a severely gangrenous type, there could be but little difficulty in admitting the same possibility as regards the vaccinia exanthem. By the term vaccinia exanthem he intended to designate a general eruption, sometimes erythematous, sometimes lichenoid, and sometimes vesicular, which, although unfrequent, was admitted by all experienced vaccinators to be occasionally seen. It had been especially described by Mr. Ceely, and was referred to by Hebra and others. It was, of course, the analogue of the skin-eruption in variola.—*Brit. Med. Journal*, Oct. 29, 1881.

Surgery.

Operations for Chronic Disease in Phthisical Patients.

At the meeting of the Medical Society of London Mr. BRYANT read the history of a young man who for some years had suffered from disease of the knee-joint, and when he came under Mr. Bryant's care there was evidence of consolidation of both apices of the lungs. The thigh was amputated, the wound healed well, and the chest symptoms improved, while the physical evidence of lung disease diminished. In short, it was a case illustrating, first, the possibility of rapid recovery from a serious operation during the course of phthisis, and, second, the fact that the removal of a chronically diseased joint may be followed by improvement in lung trouble. The case is now by no means isolated, but is one of a series, which have been published from time to time. We may study such a case from two points of view, as showing the influence of general disease upon local conditions, and the influence of local disease upon general affections.

It is not difficult to understand why general constitutional states must influence local disease processes, and it accords with all experience and preconceived ideas that the constitutional effects of pulmonary phthisis may retard, or even prevent altogether, the recovery of a chronically diseased joint. Under such circumstances amputation may be demanded for local conditions quite amenable to milder methods in patients of robuster frame. But the question arises whether the same is true of wounds. Do constitutional states play any part, or any considerable part, in the history of a wound? Hitherto the answer to such a question would have been deemed simple and distinct in the extreme—that they did. But it is now asserted, by some of the more ardent disciples of Professor Lister especially, that our present knowledge of the processes of wound healing, and of the local causes of their failure, has placed us in a position of complete independence of the general systematic condition when called upon to treat a wound. It is asserted that, in every case where certain local conditions are observed, primary union of wounds may be insured. We, at any rate, know that the *vis medicatrix naturæ* is especially exerted and manifest in the healing of injuries of all kinds, and that further knowledge merely adds to the occasions of wonder that so grave and complete injuries can be repaired. It is, however, open to us to say that probably constitutional cachexia, as from phthisis, when very marked, may arrest the healing of a wound. This position seems to be in accord with our pre-

sent knowledge, and for correction will require demonstration of its error, and not mere assertion. The practical outcome of this is, that, granted amputation to be advisable, there are certain stages of the general disease which admit of the operation, while in others it is inadmissible. Where the lung disease has passed into the third stage, and there are cavities surrounded by large masses of caseous lung tissue, where the pyrexia is marked and constant, and the other organic functions are interfered with, it would be unwise to perform any operation not immediately necessary to save life, as the surgeon's wound might not heal, and, continuing to suppurate, would be a constant drain upon the already enfeebled vital powers. This is the rule as applied to operation for fistula in ano, where it has been found to work well, and where also operating during the more severe stages of the disease in disregard of this rule has proved disastrous.

But it is the other view of such cases as Mr. Bryant's that is the more important, and was more specially raised by him at the Medical Society. This suggests two questions, Whether, and how far, local diseases of bones and joints may cause and perpetuate phthisical changes in the lungs, and whether, such visceral disease having been lighted up, removal of the diseased bone will ameliorate the condition of the lungs? Although not actually demonstrated as regards man, there is yet every reasonable probability that chronic disease of bones or joints, especially if attended with caseation of inflammatory products, may be the starting point of genuine tuberculosis. But it is by no means so probable that the more common chronic caseating pneumonia of phthisis is due to any similar cause; and although we cannot assert the negative, and may even be willing to entertain the supposition as one not unlikely to be established as our knowledge becomes more complete, we must at present explain differently the connection between such bone diseases and the common lung changes of pulmonary phthisis. The two affections may be both regarded as expressions of one and the same "dyscrasia," and a man who from an injury gets chronic caseating ostitis and arthritis may be held to be also predisposed to chronic caseating pneumonia from causes inefficient to produce such results in the robust. The pain, the enforced rest, the confinement to the house or to a close room or the ward of a hospital, disturbed sleep, impaired digestion, and especially the prolonged pyrexia, with its necessary increased oxidation and elimination by the lungs, may each and all bear some share in setting up lung mischief. If to this be added suppuration, with the constant drain upon the blood and the unnatural activity of the hæmatopoietic processes, especially in the lymphatic structures, we have a further link in the etiological chain. Should the disease processes in the lungs be once established, it is still more obvious how all these influences must retard if not jeopardize their subsidence. The harmful influence of bone and joint disease both in the causation and continuance of phthisis may thus be granted. And if the above expresses *all* the truth, the indications for treatment are plain—remove at once the offending bone or joint. But if the bone disease be of an infective nature, such a course would be merely closing the stable door after the horse was stolen, if the poison be of a nature to multiply within the body. Amputation of a caseous focus of a general tuberculosis would therefore be useless.

The cases in which this line of practice may be carried out with most hope of success are, then, those in which the pulmonary trouble is distinctly secondary in point of time to the disease of the bone, and where the bone disease is advanced and attended with pain and discharge, while the lung disease is limited in area and early in stage. In proportion as these conditions become altered the indication for treatment gradually shifts, until where the lung condition is primary, very advanced and wide in its area, or is merely a part of a general tuberculosis, and the bone disease is secondary and early and not attended with suppuration, amputation would only be the means of hastening death.—*Lancet*, Oct. 29, 1881.

New Methods of Treating Erectile Tumours.

M. CONSTANTINE PAUL presented to the French Academy of Medicine, recently, a child whom he had cured of an erectile tumour by vaccinating the growth. M. Paul claimed that he had devised a new method for treating this class of disorders. We are not aware that he claimed for his method of treatment any essential originality. At any rate, vaccination as a method of treating small nævi has long been known to English and American surgery. But M. Paul described a new and peculiar process of performing the operation for vaccination, by means of which he had obtained the specially good results to which he called attention. In vaccinating by the ordinary method it would be quite probable that some part of the tumour's surface would not become affected. In this case the cicatricial tissue resulting from the inflammatory action would be only developed at certain points, leaving the rest of the tumour unaffected. In order to secure uniform inflammatory action throughout the entire surface, therefore, M. Paul covers the tumour with a layer of vaccine lymph, and then through this punctures are made all over the parts desired to be affected.

M. Paul presented a case treated in this way with quite notable success. The patient was a little girl who had had a large erectile tumour on the back of the head. It was situated below the occiput, extending on the right side nearly to the ear. It was, according to M. Paul, at the same time cutaneous and subcutaneous. The vaccination pustule had affected the whole part, and was three months in entirely healing. The skin where the tumour had been was then completely devascularized, but there was some erectile tissue remaining beneath it. This M. Paul believed, from previous experiences, would finally atrophy and disappear.

In a subsequent discussion upon this method of treating erectile tumours, MM. Gosselin and Blot both took the ground that M. Paul's cure was incomplete, and that in all cases where there was any subcutaneous vascularization, vaccination would be nearly futile. It could, however, cure superficial erectile tumours, and in the subcutaneous forms it would at least give a hard, strong covering to the tumour, which would prevent any danger from ulceration or rupturing with hemorrhage.

Commenting upon this procedure, M. E. Ricklin (*Gazette Médicale*) refers to another easy method of treating these tumours, which has been successful in the hands of Dr. Schrumpf. This practitioner treated several cases of bandaging and compression. The tumours were very large, but were situated either on the fore- or upper-arm. By bandaging the extremity from the fingers up, the erectile tissue was made gradually to atrophy and disappear.—*Med. Record*, Nov. 5, 1881.

Visceral, especially Renal, Syphilis.

M. BARTHÉLEMY reports (*Annales de Derm. et de Syph.* 1881, No. 2, p. 272) five cases of renal disease in connection with syphilis. In the following instance the patient improved under specific treatment A woman, aged 33, who had been infected three years before, was admitted into the St. Louis Hospital, under the care of M. Fournier, in November, 1879. Six months previously she had been under treatment for mucous patches, vertigo, and pain in the head. There was at that time no albumen in the urine, and after three months' treatment the woman went out cured. In October diarrhœa appeared; and at the beginning of November œdema of the lower limbs and genital organs was noticed. On re-admission, the face also was puffy. There was intense dyspnœa, and *râles* were

audible all over the chest, but there was no dulness, nor pain in the loins. The urine was copious, and contained a large quantity of albumen. The patient subsequently suffered from an iliac abscess, but she gradually recovered under anti-syphilitic remedies, and on her discharge from hospital the urine became only slightly cloudy on the addition of nitric acid.—*London Med. Record*, Oct. 15, 1881.

—

Aspiration of Suppurating Buboes.

In a paper published in the *Annales de Derm. et de Syph.*, 1880, p. 224; and 1881, p. 308, M. Le Pileur reports nineteen cases of buboes treated by aspiration. Seventeen of the buboes were in the groin; of these, twelve followed soft chancres, six being virulent and six simple abscesses. One was in a syphilitic subject, two were consecutive to scabies, and three were strumous buboes. The remaining two were submaxillary abscesses. In buboes caused by chancre, the author advises that the pus should be inoculated after aspiration, and, if it be found to be virulent, that a solution of nitrate of silver should be injected into the bubo; thus, according to the author, other openings may be prevented. Even if the opening ulcerate, the course is said to be much milder than after the use of the bistoury. M. Le Pileur thinks suppurating adenitis of every kind ought to be treated by aspiration when fluctuation is distinct. The scar is nearly invisible, or at least insignificant. The duration of the affection is shorter than under the ordinary mode of treatment. The nineteen cases gave an average duration of about twenty-four days after aspiration. For the mode of operating, the author refers the reader to his *Etude sur les Adénites Inguinales*, 1874; but, as far as can be gathered from the cases reported, the pus would seem to have been simply drawn off through a trocar, of which the point could be concealed, and a shred of lint placed in the opening and kept there for about twenty-four hours. Poultices were also applied.—*Lond. Med. Record*, Oct. 15, 1881.

—

Scrotal Calculus.

A unique case of this affection is reported by Lippoman, in the *Wratschebuyja Wedomosti*, 1881, No. 454. The patient, a peasant, sixty-eight years old, stated that fifteen years previously he had suffered from difficulty in passing water, which finally became so aggravated that he consulted a physician, who removed from the scrotum by incision a stone weighing one hundred and twenty grammes. A urethral fistula resulted, through which all the urine passed, at first with ease, but of late with increasing difficulty. On examination a fistula was found just behind the peno-scrotal junction. All endeavours to pass a metallic or an elastic catheter per urethram were futile; only the anterior portion of the pendulous urethra was permeable. The scrotum was as large as a child's head, and was distended by a hard mass. The testicles were dislocated toward the external inguinal apertures, and were very much atrophied. On introducing a catheter into the fistula, it was arrested by a stone. On the following day an incision was carried from the fistula backward along the raphe of the scrotum, and four calculi, weighing in all forty grammes, were removed. They were rough, of a grayish-yellow colour, showed facets, and consisted of phosphates. When placed in apposition they were as large as a goose egg. The cavity left after the operation was cleansed with carbolic acid, drained, and healed kindly, leaving a fistula, through which the patient urinated. Later he emptied his bladder with the aid of a self-made catheter, consisting of a goose-quill.—*Med. Record*, Nov. 5, 1881.

A Case of Popliteal Aneurism Cured by Means of Esmarch's Bandage and Digital Compression.

E. Z. Derr, M.D., U. S. N., reports the following case: The patient, a strong, robust man, was admitted to the U. S. Naval Hospital, Norfolk, Va., on April 15, 1881. Examination revealed the existence of a large, pulsating tumour in the left popliteal space. The calf of the leg was very much larger than its fellow, and both sensation and motion were very much diminished. Owing to this condition of things, no active surgical interference was resorted to until June 10th, when Esmarch's bandage was applied, and allowed to remain on forty-five minutes. At the end of that time the pain became so intense that it was removed. Pulsation returned after the removal of the bandage, but its force was perceptibly diminished.

On June 16 another application of the bandage was made, and allowed to remain one hour and twenty-five minutes. Pulsation returned on the removal of the bandage, but its force was still further diminished.

On July 9 the bandage was again applied, and allowed to remain one hour. At the same time digital compression was made over the femoral, and continued for six hours after the removal of the bandage. Pulsation returned after the cessation of the pressure, but was greatly diminished, and the tumour was found to be much smaller and firmer.

10*th*. Digital compression was continued for two hours, causing still further diminution in the size of the tumour.

11*th*. Compression was continued for three hours to-day, with further good results.

12*th*. The compression was kept up for five consecutive hours to-day, and on the removal of pressure no pulsation could be detected.

At the present writing—September 9—a hard, fibrous mass, not larger than a walnut, occupies the site of the large, pulsating tumour which previously existed.

The case is reported because it furnished another illustration of the utility of the combined method in the treatment of popliteal aneurism.—*Medical Record*, Oct. 29, 1881.

—

Rupture of the Plantaris Muscle.

In *The New York Medical Journal and Obstetrical Review* for July, 1881, Dr. A. B. Judson gives three cases in which he diagnosticated this injury. He remarks that it is seldom found described in systematic works on surgery, although its occurrence is probably not very uncommon. Its most remarkable feature is the trivial nature, or almost entire absence, of an immediate cause. Persons are attacked while quietly walking in the street, stopping suddenly under the impression that they have been shot in the leg. Apart from ecchymosis, which is met with in but a limited number of cases, the only objective signs are œdema and deep-seated induration, and these are by no means constant. If there is an obvious gap in the muscles, with an adjacent muscular tumour, the case is to be considered one of rupture of the muscles, the term *coup de fouet* being conveniently used to indicate those cases in which the exact lesion remains undetermined. The diagnosis depends on (1) the suddenness of the attack; (2) the insignificance of the apparent cause: (3) the location of the trouble; (4) the pain, which is absent or slight when the part is at rest, and produced or aggravated by those motions of the limb, active or passive, which disturb the muscles of the calf; and (5) the great disproportion between the objective and subjective symptoms. Recovery is always protracted, and is probably not much facilitated by treatment, which, however, should not be neglected, for the prognosis is sometimes unfavourable,

especially when the affected limb is the seat of deep varicose veins, or shows traces of former phlebitis. Local and general remedies should be directed toward the relief of pain. Repair of the injured structures should be promoted by preventing motion or disturbance of the part affected. The condition which seems best adapted to secure this object is that of enforced fixation with the knee moderately flexed and the ankle moderately extended. As recovery progresses, locomotion will be facilitated by a high-heeled shoe, which prevents the foot from being unduly flexed on the leg. Cases of this injury present opportunities for the exercise of judgment in the decision of the question of abandoning further rest and resorting to motion and exercise.

—

Experimental Researches on the Forcible Straining of Genu Valgum.

M. MENARD studies in this paper (*Revue de Chir.*, 10th Sept. 1881) the lesions produced in forcible straining of the knee on the cadaver, whether with the hands or with the apparatus of Collin. Without entering, he says, upon the clinical side of the question, and without establishing a comparison between this operation and other modes of treatment, some slow and belonging to orthopædic practice, others rapid, such as osteotomy, his object is to clear up the mechanism, and to determine the lesions, of the purely operative proceeding, as constituting one of the elements which permit the question to be decided as to its fitness and uses in surgery. His conclusion is that in rapid straightening of the genu valgum by Delore's method, the operative proceeding carries the knee, not directly outwards but outwards and backwards; at the same time, there is a tendency to bend the tibia inwards on the femur, and to force the extension of the knee. The articulation resists, therefore, not only by its external lateral ligament, but also by those which limit the extension, the posterior ligament and the intra-articular ligaments. This mechanism explains why it is the femur which comes away rather than the articulation. The lesion produced is very generally the stripping of the epiphysis from the inferior extremity of the femur and a large and considerable periosteal attachment, behind and external to the diaphysis. The employment of Collin's apparatus, or of any other similar one, appears to him preferable to manual force. With the hands, somewhat less lesions are produced; the detachment of the epiphysis is accompanied with crushing of the spongy tissue; moreover, the ligaments are apt to be torn away. The results appear to be very analogous in patients from two to six years of age. Beyond that age, it is a question whether the resistance of the femur becomes greater than that of the ligaments. He thinks that even then tearing of the ligaments must be very rare if the operation is well performed. This opinion is indeed only the expression of the results obtained by MM. Farabœuf and Terrillon.—*London Med. Record*, Oct. 15, 1881.

—

A Form of Gonorrhœal Arthritis.

In the *Arch. Gén. de Méd.*, May, 1881, p. 541, MM. DUPLAY and BRUN discuss a form of gonorrhœal arthritis which, according to them, had not before been fully described. This variety of arthritis may come on suddenly, without any known immediate cause, or it may follow slight injury. Most frequently, however, it is preceded by malaise, slight fever, loss of appetite, etc. The first symptom is pain, which comes on with great acuteness. This pain begins, and is always worst, just at the spot where the articular surfaces of the bones touch each other, and is increased at night. Besides this spontaneous pain, acute suffering is caused by pressure above the joint. Swelling soon follows the pain, and it also first appears exactly at the line of junction of the bones which form the joint.

There is little or no effusion into the synovial cavity, the swelling being chiefly due to infiltration of the periarticular tissues. The œdema extends above and below the affected joint, and sometimes there is an obscure kind of fluctuation, leading to a suspicion of abscess. Two cases are mentioned in which incisions were made under this belief. The swelling is not due to effusion into the sheaths of the tendons. In the treatment of this form of arthritis, the most important point is absolute rest of the joint by means of a plaster-of-Paris bandage. The pain then soon disappears, and, in favourable cases, the joint recovers almost entirely. If, however, the joint be not fixed until several days after the onset, more or less stiffness is likely to remain; and if the affection be neglected altogether, ankylosis will probably occur; indeed, this sometimes happens in spite of careful treatment. The wrist and the elbow appear to be the joints most frequently attacked, while the knee, which is frequently the seat of the effusive form (hydrarthrosis) is comparatively seldom involved. However, any joint may suffer, and the authors have seen marked examples of this form of arthritis in the metacarpal, phalangeal, and sterno-clavicular articulations. But whatever joint is attacked, the symptoms are essentially those which have just been described. The paper concludes with notes of six cases (three of the patients being women), illustrating the various points already mentioned; the chief features of this form of joint-affection are the occurrence of pain and swelling, which always begin and remain most marked exactly at the interarticular line, the presence of crackling, and the liability to ankylosis if the joint be not fixed early.—*Lond. Med. Record*, Oct. 15, 1881.

—

Treatment of Floating Bodies in the Knee.

In a recent contribution to the *Rev. de Chir.* (Nos. 5 and 6, 1881) Dr. G. GAUJOT, of the Hôpital du Val-de Grace, states that, since the inquiry of Baron Larrey, in 1861, on the treatment of floating bodies in the knee, direct extraction through a free incision has advanced much in the favour of French surgeons. The subcutaneous operation, though sound in principle, is often attended in practice with certain risks and disadvantages. Penetration of air and blood into the articular cavity cannot always be avoided, and is very likely to result, when through the size of the foreign body it is necessary to cut freely with the tenotomy knife, or when the synovial membrane is much lacerated. This result exposes the patient to the risks of synovitis, which either may be restricted to the plastic form, or may become purulent. Plastic arthritis, in consequence of the functional impairment in which it results, is a serious complication, and purulent arthritis is very often fatal. Another disadvantage attending the subcutaneous operation is the frequent difficulty and, in some instances, the impossibility of effecting extrusion of the floating body through the orifice made in the synovial membrane. Again, during the interval between the first and second stages of the subcutaneous operation, there is always a risk of the foreign body slipping back into the joint, as there is very little tendency for it to contract adhesions to the peri-arthritic cellular tissue. This result is the more likely to occur when the synovial membrane has been freely incised, and when the foreign body has not been moved to any great distance from the opening into the joint.

It is stated in this communication that the death-rate from direct extraction has, during the past fifteen years, been reduced from twenty-two to seven and a half per cent. The author endeavours to prove that this reduction is not solely due to the influence of Listerism. An analysis of fifty-four collected cases in which arthrotomy has been performed since 1863, indicates that a like success to that attained after the use of Lister's method, may be attained by other antiseptic methods, and, indeed, after the use of ordinary dressings. Of twenty-nine

cases of floating body treated by arthrotomy, in which Lister's dressing had been applied, two were fatal; whilst of eighteen cases in which ordinary non-antiseptic dressings had been applied, only one had a fatal termination. Such a result, it is pointed out, need not cause surprise if one considers the success that has been attained in ovariotomy and enterotomy by Mr. Kœberle, who does not make use of Lister's dressing.

Articular synovial membranes, when affected by chronic hydrarthrosis, acquire, like other serous membranes that have been exposed to the prolonged contact of morbid products, a certain degree of tolerance that renders them less irritable and less liable to become acutely inflamed. When chronic hydrarthrosis is associated with a floating body within the joint, the tolerance of the synovial membrane is increased through the nature of the original articular affection, since, in changes due to rheumatism, there is much less tendency to suppurative inflammation. In order to insure success after direct extraction of an articular floating body, certain precautions must be taken in order to avoid acute synovitis. Such precautions consist in preventing the free access of air to the interior of the joint; in making a clean and small wound; in avoiding as much as possible irritation of the synovial membrane during the removal of the floating body; and in the exclusion of any septic agent. These evils, M. Gaujot holds, may be guarded against without resorting to any strict antiseptic treatment. In considering the question whether the extraction of an articular floating body can insure a permanent cure, the author states that it is to be remembered that in most cases the foreign body does not constitute in itself the articular lesion. It is very often but an epi-phenomenon superadded to primordial changes of a chronic arthritic character.

The operation usually results in the disappearance of the phenomena due to the presence within the joint of a foreign body, but it does not remove the other results due to antecedent articular changes. There may be a cessation of the characteristic pain and less interference with locomotion, but the symptoms of chronic hydrarthrosis, such as swelling of the joint, crepitus, and a restricted range of articular movements, will too often persist. A decision as to the probability of recurrence should be based rather on the form and composition of the floating body, than on the condition of the joint. The prognosis is favourable in those rare cases in which this body consists of a fragment of bone, or a fibrinous concretion, whilst the indications are just the reverse when it presents one of those many forms which have their common origin in fibro-cartilaginous proliferation of the synovial elements. M. Gaujot states, in concluding, that the operation of direct extraction, though one of very little danger, ought not to be practised save in cases where the functional disturbance is severe, and palliative treatment has already been applied, but without success.—*Lond. Med. Record*, Oct. 15, 1881.

—

Rare Accidents.

In the *Medical Times and Gazette* for October 15th, Mr. CHARLES MCIVHOR GOYDER reports three cases of accidents, which are interesting from the extraordinary character of the injuries. The first case is one of *compound comminuted fracture of the astragalus without fracture of the malleoli*, occurring in a very large and heavy man, and produced by slipping from a pile of chain and falling on his foot from a distance of about two feet. Upon examination, the foot appeared inverted, the external malleolus projected about an inch through a transverse wound over the outer ankle. There was no fracture of the malleoli, but the lower end of the fibula was cleanly divested of all the structures attached to its tip. Upon introducing a finger into the wound, two small chips of bone came away, cancellous in structure and covered in part by a compact layer; a great

many smaller fragments were removed from the ankle-joint, when the astragalus was found to be almost completely broken up into comminuted fragments. There was no bleeding, and the foot in other respects was quite natural in appearance. The case was treated antiseptically, and placed upon a back-splint with foot-piece, and two side-splints.

The patient did well for two months, when he got an attack of phlegmonous erysipelas. An abscess formed, which travelled up the sheath of the peronei muscles, and was opened; after which the wound quickly healed, and the patient became an out-patient a month later, his leg and foot being placed in an immovable bandage.

Five years afterwards the injured leg was slightly shorter than the other, but not enough so to make him limp; there was good movement in the ankle-joint, and he can bear the whole weight of his body on his foot.

The second case is one of a *depressed fracture of the malar bone without external wound*, produced in a man while intoxicated, by falling and striking his cheek on the curbstone. When the ecchymosis and swelling were reduced, the malar bone was found to be depressed under the orbit, forcing the eyeball upwards and forwards; there was, however, no interference with sight or with the action of the orbital muscles, and examination showed the fundus to be normal. The man subsequently recovered without any marked deformity.

The third case is an *upward dislocation of the scaphoid bone of the tarsus*, produced by falling a distance of seven or eight feet on the toes and forward part of the right foot. On examining the foot there was a marked prominence in the situation corresponding to the scaphoid bone, wider from side to side than before backwards, with edges well defined, but covered by upraised tendons, etc. The foot was partially extended at the ankle-joint, and its inner border somewhat short. There was a noticeable arching of the sole of the foot, and flexion of the ankle-joint caused great pain. Reduction was easily accomplished under chloroform, and recovery occurred without complications.

Midwifery and Gynæcology.

The Mobility of the Pelvic Articulations.

Dr. KORSCH, of St. Petersburg, contributes to a recent number of the *Zeitschrift für Geburtshülfe und Gynäkologie* an account of an experimental investigation of the above subject. He had dilators so constructed that two opposite parts of the instrument could be separated, and both the extent of their separation, and the force required to effect it, measured. This instrument he applied to different parts of the pelvic cavity, and measured the extent to which its diameters could be altered, and the force required to do it. His experiments were made on the bodies of recently delivered women, of pregnant women, of non-pregnant women, and of men. The following are the conclusions he comes to: 1. Both during pregnancy and in patients suffering from large uterine or ovarian tumours, there is not only yielding of the pelvic articulations, but widening of the pelvic diameters. 2. At the pelvic inlet, the greater widening is of the transverse diameter; at the outlet, of the antero-posterior diameter. 3. To enlarge the pelvic inlet requires nearly double the force needed to widen the outlet. 4. Widening of the transverse diameter of the pelvic inlet is accompanied with shortening of the antero-posterior diameter; but widening of the latter does not alter the former. 5. When the transverse diameter of the brim has been enlarged to the maximum extent, the conjugate may still be slightly lengthened;

but when the maximum increase in length of the conjugate has been attained, the transverse diameter cannot be widened. 6. When the transverse and antero-posterior diameters of the inlet are simultaneously expanded by pressure, the amount of increase in each is not so much as when each is separately expanded. 7. Widening of the pelvic outlet diminishes slightly the conjugate, but leaves unaltered or slightly increases the transverse diameter of the brim. 8. The converse takes place when the inlet is widened. 9. In the majority of the cases the greatest amount of mobility was in the sacro-iliac synchondrosis. 10. In those joints of which the mobility was increased, the quantity of synovial fluid was usually somewhat greater. 11. Lengthening of the antero-posterior diameters depends upon the movement of the sacrum; that of the transverse diameters upon yielding of the symphysis pubis. 12. Increase in size of the synovial cavity of the pubic articulation leads to a greater mobility of the joint. 13. The number of deliveries has, apparently, no influence on the mobility of the pelvic articulations.—*Med. Times and Gaz.*, Oct. 29, 1881.

—

A Peculiar Condition of the Cervix Uteri which is found in Certain Cases of Dystocia.

In support of the position taken in his earlier communications, that tonic spasm of the internal os is a more frequent cause of dystocia than the statements of the text-books would lead one to suppose, Dr. ALFRED HOSMER has collected notes of a number of additional cases where this condition of the cervix was found to interfere with labor. His conclusions are as follows:—

1. Simple elongation of the cervix, even though it be excessive, disables the uterus by perversion of its force, renders spontaneous expulsion improbable, but in connection with artificial delivery does not produce a condition of things to which the term dystocia can be applied with any propriety of significance.

2. Tonic spasm of the internal os may in single labor be developed so early as to imprison the whole fœtus in the cavity of the uterine body, and in a multiple labor its production may be so postponed as to interfere only with the birth of the last child. Its existence cannot necessarily be referred either to pelvic deformity, to extreme elongation of the cervix, or to the occupation of the cervical cavity by any portion of the unborn child.

Finally, tonic spasm of the internal os has shown a marked tendency to recur in the successive labors of those who have once or even twice survived the danger to which it exposed them, and the patient in whom it occurs for the first time is not necessarily a primipara.—*Boston Med. and Surg. Journ.*, Oct. 20, 1881.

—

Exfoliative Vaginitis and Membranous Dysmenorrhœa.

It has been a common reproach to gynæcologists that they are too fond of assuming that disorders of the general system, more particularly hysteria and allied nervous symptoms, when met along with uterine disease, are its result. Dr. COHNSTEIN, in a paper on the subject of membranous dysmenorrhœa and exfoliative vaginitis, published in a recent number of the *Archiv für Gynäkologie*, goes to the other extreme, and, reasoning from a number of cases which he has collected (which collection makes his paper very valuable for purposes of reference), concludes that membranous dysmenorrhœa is not the cause, but the result, of hysteria, or of disorder of the general health. He points out that in nearly all the cases of his collection the general health was much deteriorated; that we know of no local treatment which will cure membranous dysmenorrhœa; that membranes are sometimes passed at the menstrual period without pain; that

in many cases impairment of the general health preceded the painful menstruation. It is very difficult to see in what way hysteria should so modify the functions of the uterus as to make it excrete a membrane each month; and hysteria itself is a thing so difficult to define that it seems hardly possible that proof should be forthcoming of Dr. Cohnstein's theory. But, without going as far as he does, we think he has done good service in calling attention to the facts that nervous and hysterical symptoms going with uterine disease are not of necessity caused by it, and that menstrual pain is modified by the state of the general health in this way—that an amount of pain which a strong, healthy woman would think too trifling to mention, will put a feeble, neurotic individual quite *hors de combat*. In the latter case treatment of the general health may, without modifying the local condition, so improve the patient's power of bearing pain as to remove her from the condition of invalidism.—*Med. Times and Gaz.*, Oct. 8, 1881.

—

The Origin of Tubo-Ovarian Cysts.

Dr. HENRI BURNIER contributes to the *Zeitschrift für Geburtshülfe und Gynäkologie* a case of the above rare kind, which occurred in the practice of Professor Schroeder. The patient gave a history clearly indicating antecedent peritonitis. When the cyst was removed, it was found that the Fallopian tube, much dilated, opened directly into it, the opening being as big as a shilling (*Markstückgrosse*). Ray-like processes of mucous membrane, continuous with and resembling that of the tube, spread out from the opening over the inner wall of the cyst, some of them meeting at the opposite pole of the cavity. This mucous membrane was everywhere covered with cylindrical epithelium. On examination of the cyst-wall, Graafian follicles could be found, more or less abundantly, in every part of it, except where the tube entered it. The mode in which Dr. Burnier supposes this tumour to have arisen is the following:—First, an attack of peritonitis causing adhesion of the peritoneal surface of the fimbriæ of the tube to the ovary. Then, a Graafian vesicle ripening and coming to the surface at the site of this adhesion. Owing to the greater resistance caused by the inflammatory thickening, this follicle cannot burst, but becomes distended into a cyst (hydrops folliculi). At the same time, the secretion of the Fallopian tube, being retained, dilates the tube (hydrosalpinx). We thus have two collections of fluid, separated by a septum consisting of the wall of the follicle and the fimbriæ of the Fallopian tube. This septum becomes absorbed, and a tubo-ovarian cyst is the result. The adhesion between the tube and the ovary at the site of the dropsical follicle prevents this from projecting from the surface of the ovary, as such follicles are wont to do, and therefore it can only grow by stretching out the healthy tissue of the ovary round it. Hence the presence of Graafian vesicles at every part of its circumference. Dr. Burnier examines the recorded cases of tubo-ovarian cyst. Three of them, he finds, support this theory, and the others contain nothing against it. The theory of Veit, which assumes the coincidence of catarrh of the tube and hydrops folliculi, Dr. Burnier regards as quite compatible with his own view. Richard's theory, that the fimbriæ of the tube embrace the ovary at the time of bursting of the follicle, and that the tubo-ovarian tumour results from the bursting of a dropsical follicle, and effusion of its fluid into the tube, Dr. Burnier regards as untenable—first, because there is not enough evidence that the fimbriæ do embrace the ovary when the follicles break; and, secondly, because it does not account for the presence of cylinder epithelium within the tumour.—*Med. Times and Gaz.*, Oct. 15, 1881.

Incomplete Removal of Ovarian Cysts.

M. TERRIER (*Revue de Chir.*, 10th Aug. 1881) puts the following question: Does the incomplete removal of ovarian cysts, resulting from the existence of extensive solid or vascular adhesions to important organs, give, as has been said, deplorable results, and should it be avoided uniformly, as Kœberlé advises; or is it, on the other hand, an operation which is acceptable, and even a method counselled sometimes by prudence, and not by necessity (Péan)? M. Terrier relates some private cases, and examines the recent publication of cases and statistics by Spencer Wells and Péan, with the following results: 1. Incomplete operations ending with the opening of the cysts, suture of the walls to the abdominal wound, and drainage, give very different results, according to the nature of the cystic tumour. 2. When the cyst is unilocular—as serous cysts and dermoid cysts of the broad ligaments are—the results may be excellent, and the cystic cavity ends by being completely filled up. 3. The same result is perhaps possible in certain cysts which are unilocular from a clinical point of view, but which anatomical pathologists class as multilocular cysts. 4. When the cyst is multilocular, and when the cystic walls are clothed with vegetation, the results are very different. The tumour tends constantly to relapse, the abdominal fistula persists, and the interminable suppuration exposes the patient to chronic septicæmia and exhaustion. 5. Finally, it is to be noted, both in the case of young and of multilocular cysts, that there is a possibility of the rapid development of a tumour already pre-existing on the ovary, which has not been touched, and of which the conditions could not be verified at the time of the operation.—*London Med. Record*, Oct. 15, 1881.

Medical Jurisprudence and Toxicology.

Detection of Arsenic in Wall Papers.

Dr. WILLIAM B. HILLS takes exception to the wide publicity given to the nitrate of silver as a test for arsenic in wall-papers. He asserts that it is one of the *least* reliable tests for the purpose mentioned. The cases in which the nitrate of silver test gives fairly reliable results are comparatively few, and are essentially the ones in which arsenite of copper (Scheele's green) or aceto-arsenite of copper (Schweinfürt green) is used as a pigment, unmixed with other substances. These arsenical compounds are, however, seldom thus used, but are commonly employed in combination with other substances, by which means the green color is modified and various tints are obtained, in which, as a rule, the arsenical green cannot be detected by any physical appearance. Under these circumstances the above test will ordinarily fail to indicate the presence of arsenic, and particularly so if the arsenical green be mixed with organic pigments. Many of these latter, when treated with ammonia, furnish colored liquids, the color varying with the nature of the organic pigments. If nitrate of silver is added to such a liquid, any precipitate produced, whatever its true color may be, will ordinarily assume the color of the liquid. For example: yellow arsenite of silver will usually *appear* red in a red liquid. Obviously no conclusion can be drawn in such cases as to the presence or absence of arsenic. Again, the yellow sulphide of arsenic is sometimes used, and arsenic in such cases cannot be detected by nitrate of silver. The test is also useless in detecting arsenious acid in the aniline colors. Dr. Hill's method of proceeding is as follows: Take a sample three or four inches square, cut into small pieces, moisten with concentrated sulphuric acid, and heat carefully

until the paper is thoroughly charred. Let the charred mass cool, add to it about one fluidounce of water, grind up the black mass so that the water may come in contact with all parts of it; filter and wash. The arsenic will be found in the filtrate, which is to be examined by Marsh's test. All chemicals must be free from arsenic. A paper which, treated carefully in this manner, furnishes no arsenical stain on porcelain, does not contain any appreciable amount of arsenic.—*Louisville Med. News*, Oct. 15, 1881, from *Boston Med. and Surg. Journal.*

—

Poisoning by Carbolic Acid.

Two cases of poisoning by carbolic acid are reported in abstract in the last number of the *Nordiskt Medicinisk Arkiv.* One of them, described by Dr. J. A. Malmgren, is that of a child aged 5½ months, who had an eruption, followed by an ulcer in his groin, which was ordered to be dressed with carbolized oil (8 per cent.). The next day, he had vomiting, which was repeated during the night. The urine was described by the mother as being "very dark and foul," and the child was very sleepy. The carbolized oil was removed on the third day; the urine was of a deep coffee-colour, and the child slept almost constantly; the pupils were somewhat contracted; the vomiting continued. On the fourth day, the patient's condition was about the same; but in the evening the somnolence had ceased, the vomiting was less frequent, and the urine had become much clearer. The child recovered; but the urine retained a dark colour for a fortnight. In the second case, related by Dr. Nordenström, a child one year old had a large fluctuating swelling in the left parotid and submaxillary regions; it was opened, and a large quantity of pus discharged. The part was dressed with cotton-wool saturated with carbolized oil (1 in 10), over which were placed dry cotton-wool and a bandage. The dressing was changed morning and evening. About an hour after the application of the dressing, the child had vomiting, which continued through the following day. The urine was of a dark green colour, and the evacuations were loose. On the third day, the condition was about the same, and the breathing was impeded. A mixture of equal parts of camphorated oil and olive oil was now substituted for the carbolized oil; but the child died the next morning.—*Brit. Med. Journal*, Oct. 22, 1881.

—

Case of Poisoning by Atropia.

The patient, a small, weak, anæmic child, aged 6, took by mistake, between 8 and 9 in the morning, a teaspoonful of a solution of atropia, 0.05 to 10.0, or about 35 milligrammes (a little more than half a grain). His face soon became flushed, his gait staggering, and his voice hoarse. An hour later antidotes were administered, including tannic acid, iodide of potassium, and injections of infusion of jaborandi. Soon the patient exhibited hallucinations, and became delirious. Seven and a half hours after the dose had been taken, REINL (*Prag. Med. Wochenschr.*, No. 20, 1880) saw the child, who was restless and unconscious and still delirious, the pulse being 140 and respirations 30. A hypodermic injection was given of 5 centigrammes of morphia (about three-fourths of a grain), and in ten minutes the pulse fell to 100 and the respirations to 20. The restless movements subsided, and in half an hour the patient slept, the pulse falling quickly to 96, and the respirations to 18. The following morning, after a good night's rest, the child was quite cheerful, though there remained twitchings of the muscles of the face and extremities which continued three days. [This case affords no proof that morphia is an antidote to atropia. Children are curiously insusceptible to the action of belladonna. Holthouse has recorded the case of a

boy, aged 3½ years, who recovered after taking half a grain of atropia; and there have been cases of recovery after taking 0.5, 0.6, 1.0, and 1.5 grains respectively. The injection of an infusion of jaborandi could hardly be expected to do any good. It is true that a hypodermic injection of a one-hundredth part of a grain of atropia will instantly check the perspiration and salivation of jaborandi, but the converse is not the case. Atropia is a much more powerful alkaloid than pilocarpin; and in a case of poisoning by atropia recently recorded by Purjesz, of Buda-Pest, as much as 6½ grains of hydrochlorate of pilocarpin had to be administered hypodermically, before any antidotal properties were observed. It is interesting to note the fall in pulse and respiration after the injection of the morphia. It would appear that, although morphia is not an antidote to atropia, it will retard the restlessness and delirium caused by a poisonous dose of that alkaloid.—*Rep.*]—*London Med. Record*, Oct. 15, 1881.

—

An Accident with Hydrofluoric Acid.

Fluorine as an element is as yet unknown, it never having been isolated. The reason of this is that it is so destructive to all apparatus used for the purpose. It has been studied in its compounds and reactions, and its atomic weight has been determined indirectly. It is the only element which has no known compound with oxygen. It unites with many other elements as a monatomic acid radical and forms fluorides and also forms quite a number of double salts. Nearly all these compounds affect glass in the presence of moisture. Its hydride is a strong acid like that of chlorine, and is a gas. It dissolves many of the metals to form fluorides, is easily absorbed by water, and hence the liquid acid is obtained by saturating distilled water with the gas. It has little effect upon platinum or lead, and is transported in gutta-percha bottles as it affects neither this nor wax nor paraffine, but its action upon other organic substances is often very energetic. Mr. ROBBINS, Assistant in the Boston Institute of Technology, once attempted to redistil some of this acid as it is formed in these bottles, but neglected to dilute it one-half, as is usually done when it is wished to condense it without a freezing mixture. When heated, the gas began to come over without condensing. It charred the wooden box which surrounded the receiver, and dissolved and volatilized a piece of writing paper which was exposed to it, leaving only a slight film of a gelatinous substance, probably the gum from the sizing of the paper. Concerning the action of this acid upon animal tissues, little is known. Wurtz's dictionary gives the fullest account of it. He says in substance that it corrodes the skin, giving rise to insufferable pain, and produces a deep ulcer which is very difficult to heal; small drops of it being sufficient to produce white and painful blisters. The reporter had not read this, and was not aware of the great severity of the action of this acid, and carelessly used the stump of a match, the wood of which was saturated with the acid above referred to, to remove the lime, etc., from the surface of a piece of porcelain so as to obtain the freest action on the part where it was desired to etch a hole. When he first noticed that it was getting upon his fingers, he washed them and greased them with tallow, and thinking they were sufficiently protected, he went on with his work. For about an hour and a half he had the match in his fingers the greatest part of the time. Just before getting the hole through, he noticed that the ends of his forefinger and thumb were beginning to be unsensitive, and felt a curious sort of dull pain that perhaps might best be described by saying that the fingers "hurt" a little. When through he washed them well, applied dilute ammonia water and washed that off, and then applied bicarbonate of soda, but these measures did not relieve the pain from soon becoming very uncomfortable, and the fingers

were dressed in a mixture of linseed oil and lime-water, as it felt more like a burn than anything else. This was done between 11 and 12 A. M. That afternoon the pain gradually increased, and in the evening Dr. Blodgett was consulted.

At this time the ends of the fingers were white and very hard; so hard, indeed, as to dull the scalpel with which he endeavoured to cut away some of the skin. The action was still going on, and as the depth to which it had penetrated could not be determined a dressing of cold cream was applied, and later vaseline was used, but neither seemed to allay the steady increase of the pain which now most nearly resembled the sensation of a burn when held near the fire. The only relief obtained was by the application of cold, and this was only partial, and the only variation in it was from bad to worse, and at last it became the most severe pain imaginable, and it was not till four o'clock the next morning, and with the aid of 110 drops of laudanum, that sufficient relief was obtained for a broken nap. The next day the pain had subsided, and the acid had penetrated quite a distance below the skin, rendering the flesh totally insensible and hard, having abstracted all the water from it. The other fingers were only slightly swollen, and the swelling did not extend back as far as the hand, showing that the blood was not poisoned at all. The course of treatment was to remove the destroyed tissue. This it was thought best not to do with the knife, but poultices alternating with frequent soakings in very hot water were constantly employed, which proved effectual, although slow, in its operation, it being fully twenty days from the time of injury till the slough was all removed. It was very dry and tough, and by no means inclined to separate from the surrounding tissues. In four weeks all dressings to the fingers were abandoned, and he was able to use them a little. Only a small permanent loss of tissue has resulted, but now, after three months, the scars are tender, and the sensation is perhaps permanently destroyed. This agrees with the action of this acid as stated by Wurtz, especially as regards the pain, but he does not mention the very important fact that no pain is felt for some time after contact with the acid, which, in the case reported, was between one and one and a half hour, and by this time the surface has become so hard that it is difficult, if not impossible, to check the action underneath, so that the damage is for the most part done before one finds it out.

The difficulty in healing appears to consist in removing the slough, as it heals very quickly when this is out of the way, and after the first siege of pain, which is a long and severe one, the sore is no more painful than any other of equal size. The author thinks that, should he meet with the same accident again, he should lose no time in washing it off as thoroughly as possible and then apply water-glass if this were accessible; if not, an alkali should be used, and if possible the part soaked in water as hot as could be borne, and then cold cream applied or some other dressing which will keep the part soft and also exclude the air.

Mr. Robbins also heard of two other persons who have had misfortune with this acid; they were Dr. C. F. Folsom and a Mr. Lodge. The latter had the end of his thumb badly burned. It was three months in healing, and quite a loss of substance resulted. Books on chemistry and teachers of the science should give greater precautions as to the use of this dangerous reagent.—*Boston Med. and Surg. Journ.*, Oct. 27, 1881.

MEDICAL NEWS.

To Subscribers.

With this number ends the thirty-ninth year of the "Medical News," and also its publication as a monthly. But two professional periodicals —the "American Journal of the Medical Sciences" and the "Boston Medical and Surgical Journal," are still issued, of those which were in existence at the time of its birth, and during the long period through which it has made its regular monthly visits to its readers, it has witnessed the rise of all the rest of its valued contemporaries, many of which started under flattering auspices only to fulfil a comparatively brief career.

It is with feelings of thankfulness to those whose steady support has enabled it already to outlast a generation that its conductors are able to say that it has not only passed in safety through the numerous financial and political vicissitudes which have wrecked so many promising enterprises, but that the increasing demands upon it have necessitated at last a change, which has been for some time in contemplation, whereby it will be greatly enlarged in size and converted into a weekly, thus fulfilling more perfectly the mission, which it has always had in view, of conveying to the profession early intelligence of all that is of importance to the practitioner. With this object, very extensive and complete arrangements have been made. The editorial staff has been enlarged; assurances of active collaboration have been received from the leading members of the profession throughout the entire country; the services of correspondents have been engaged in every large centre of professional activity throughout the world, and a larger reportorial corps has been organized, so that nothing may be lost, whether in the sphere of clinical observation and experience, original thought, or prompt announcement of improvements and discoveries in the medical sciences wherever originating.

For further details as to the plan of the Weekly "News" and its terms to subscribers we refer to the prospectus of the publishers, and to the forthcoming January number itself, which will be shortly issued, and a copy of which will be duly laid before each of our readers. We will only add that a design so extensive, and so much in advance of anything that has hitherto been attempted for the service of the medical public, can only be rendered permanent by commensurate support on the part of the profession—a support very far beyond that hitherto conferred on even the most successful of our medical periodicals. To aid in obtaining this the publishers feel that they can rely upon their old subscribers, not only in view of the friendly association created by prolonged intercourse, but

also from the conviction that the wider the circulation of the WEEKLY NEWS, the more perfectly it will be enabled to discharge the functions which it will assume, of a medical newspaper indispensable to all who desire to keep themselves abreast of the progress of medical knowledge.

When the NEWS was started, the population of the United States was less than nineteen millions. We now number fifty millions, with five millions more among our Canadian neighbors—in all fifty-five millions of the most active, intelligent, and progressive race among men. With the wants of such a population to be supplied, the conductors of the WEEKLY NEWS feel that there must be an opportunity for establishing a medical journal on a scale not heretofore attempted, and it will be their earnest effort to fully discharge in every way the very serious responsibilities of the task which they have undertaken.

—

Ovariotomy under "Modified Listerism."—Dr. GEO. GRANVILLE BANTOCK, in the *Lancet* for Sept. 17, 1881, describes his present method of performing ovariotomy. By the term "Modified Listerism," he means that all the manipulatory details of "Listerism" are followed during the operation, but for the spray, etc., plain water is used instead of what was supposed to be a germicide solution of carbolic acid. The instruments are kept covered in trays with warm water, the hands and sponges are washed with the same, and a spray is made to play *over*, but not *upon* the abdomen. Particular attention is drawn to the mode of using the spray. Previous to October last it was directed upon the abdomen from the right front, so that whenever the parietes were lifted up the cold acid vapour was forced into the cavity from a distance of about four feet. The author thinks that this continuous blast of spray, passing freely as it did over all the parts exposed, produced a very decided cooling effect. The powers of the patient were thus inevitably depressed, and an unnecessary and injurious amount of carbolic acid was thrown upon the peritoneum. Now, following the example of Dr. Keith, the spray producer is placed at a distance of eight or ten feet behind and to the left of the patient, so that the spray passes over, but does not fall upon the field of operation, except in very minute quantity, and without any cooling effect. In this way the peritoneal cavity, in sponging out or looking for bleeding points, is left untainted, and the patient is not chilled. The spray is never used for dressing after the operation, even in drainage cases.

It may be in the recollection of some that at the time of reading of the author's paper before the Royal Medical and Chirurgical Society, it was stated that he had already reduced the carbolic solution to 1 in 100, and intimated that in consequence of the improved results obtained, he should probably dispense altogether with the phenol. After employing this solution in twenty cases, with only two deaths—one from shock and the other from acute uræmia—and with a diminished pyrexia among the recoveries, two ovariotomies were performed and a combined oöphorectomy and hysterectomy with a further dilution of the solutions to 1 in 150. These cases proving still more clearly that the motive was in the right direction, he finally threw aside *all* the acid, and resorted to the pure water metho now followed with apparently equally good results.

—

Early Experiments in Bovine Inoculation.—It is generally supposed that the attempt to prevent the contagious diseases of animals by prophylactic inoculation, after the manner of vaccination, is entirely a result of the latest development of

pathological science. M. Bouley, however, at a recent meeting of the Académie de Médecine, pointed out that this is an error. In 1852 a similar attempt was made in Holland. The experiments were designed to confer immunity against the contagious pleuro-pneumonia, the infectious nature of which, and the protection conferred by an attack, however mild, were pointed out in 1850 by a French Commission appointed at the suggestion of M. J. B. Dumas. The Dutch experiments, however, failed completely, probably in consequence of the mode of inoculation. The place selected was the loose skin below the neck, where the subcutaneous tissue is abundant. When the virus of pleuro-pneumonia is inoculated into such loose cellular tissue, it causes a rapid inflammatory infiltration of such intensity that gangrene and death almost certainly ensue. If, however, the inoculation is made in a situation in which the subcutaneous cellular tissue is dense and scanty, the local effects are slight; the animals escape the immediate results of the inoculation, and acquire the desired immunity. This was recognized a little later by a Dutch observer, Willems de Starrett, who chose the root of the tail as the place of inoculation. Of sixteen oxen inoculated in the throat, twelve died from the local process. Of sixteen others which were inoculated on the tail, all survived; and in all subsequent inoculation in the neck had no effect.—*Lancet*, Oct. 1, 1881.

—

Hospitals for Contagious Diseases.—The New York Board of Health is about to erect some new hospitals for the reception of contagious diseases upon North Brothers Island, which was granted to the city of New York for the use of the Health Board by the last Legislature. The island is situated in the sound near Port Morris. It has an area of about 13 acres, and is well adapted, both by its size and its isolation, for the sites of the proposed hospitals. One of these, which will be exclusively for smallpox cases, will be erected on the northern shore of the island. It will be of brick, and two stories in height. Other hospitals will be built for patients suffering from typhus fever, diphtheria, and scarlet fever, after the island has been provided with a sea-wall and properly graded. $40,000 have been appropriated for these improvements, but much more will be required. It is hoped that the smallpox hospital will be completed early in the spring of 1882. As soon as the new hospitals are finished, the Riverside Hospital on Blackwell's Island will be abandoned. The Health Board has recently purchased a swift and stanch steam-launch, which is used to convey cases of contagious diseases to the Riverside Hospital, and to carry those who die from such diseases to their burial-place on Hart's Island.

—

Rules for Authors.—Dr. BILLINGS, in his able, practical, and witty address before the London Congress, laid down the following cardinal rules for authors in the preparation of journal articles, which we heartily endorse:—

1. Have something to say. 2. Say it. 3. Stop as soon as you have said it. 4. Give the paper a proper title.

—

The Laryngological Congress.—At a meeting of the sub-section for the Diseases of the Throat of the International Medical Congress, the following resolution, moved by Professor Schnitzler, of Vienna, was carried unanimously: "That, opportunity having now been afforded for the first time to laryngology to show its capabilities at an International Medical Congress, and its place amongst the recognized specialties being now fully secured, a repetition of isolated Laryngological Congresses is the less required; and that it is therefore desirable to abandon the plan adopted at the first Laryngological Congress held at Milan last year of holding a second meeting next year at Paris." Although the Section and the

Congress are not the same bodies, and a resolution of one is not binding on the other, it is evident, that, as this resolution was carried by a meeting at which nearly all the leading laryngologists were present, the special Congress is practically merged in the International Medical Congress.—*Lancet*, Sept. 24, 1881.

—

Health of New York.—The sanitary condition of the city is not so satisfactory at the present time as it was during the months of September and October. During the four weeks ending November 19, there were 2655 deaths. During the same period there were 484 cases of scarlet fever as contrasted with 320 in August and 259 in September. 70 cases of variola were reported, against 75 in August and 46 in September. The number of rubeola cases for the corresponding weeks was 77, instead of 96 and 36, which were the numbers, respectively, for August and September. On the other hand, diphtheria diminished from 355 in August and 276 in September, to 270 during the period in question. The case of supposed typhus fever, reported to have occurred in October, was discovered at the autopsy, conducted under the supervision of one of the Health Commissioners, not to have been a case of that disease. No genuine cases of typhus have been observed in New York since August 27. Nearly all the proprietors of factories at Hunter's point have adopted methods of manufacture which involve a minimum pollution of the atmosphere. The odours emanating from that quarter are consequently much less penetrating and offensive than formerly.

—

Listerism at Montpellier.—In a clinical lecture, delivered by Prof. DUBREUIL at the St. Eloi Hospital, Montpellier, on a case of amputation (*Gaz. Méd.*, September 17), he observed: "Here we are working with bad surroundings, for we have to complain alike of the faulty construction of our wards, of the unsuitable manner in which they are kept, and of the defective services of the subaltern attendants, who are insufficiently looked after. So that, prior to the adoption of Lister's method, the results of our operations were detestable; but, thanks be to God and to Lister, all this is now changed, and death after amputation has now become a rare exception, while formerly it was the rule. You observe that I rigorously follow out the precepts of the antiseptic method, for I really cannot understand that mania of some surgeons, who will persist in modifying the precepts of the master, even at the risk of compromising the results. As for me, I follow them out literally, and I declare to you that, in my eyes, the surgeon who at the present time does not adopt the antiseptic method commits an act of criminal folly and odious inhumanity."—*Med. Times and Gaz.*, Oct. 1, 1881.

—

A Solvent for Quinia Sulphate.—Dr. R. C. KENNER, of Batesville, Ark., recommends (*Louisville Med. News*, Nov. 5, 1881) the solution of quinia in sweet spirit of nitre, in the proportion of twenty grains of the salt to the ounce of the solvent, in cases where there is inability to swallow pills.

—

The New Manhattan Eye and Ear Hospital, at the corner of Park Avenue and Forty-first Street, was completed on the first of October. It is substantially constructed of red brick with brown-stone trimmings. It has a depth of 100 feet on Forty-first Street, and a frontage of 60 feet on Park Avenue. The walls of the entrance hall, the passages, and the staircase walls are of red brick. The two lower floors are built of brick arches and iron beams, which are covered with ornamental tiling. Out-door patients will be received in the basement and the first story. The second and third stories contain wards and private rooms for the accommodation of patients requiring treatment in the hospital. The capacity of these two floors will be about 80. The fourth floor contains two

wards and some private bed-rooms. The kitchen is also located upon the fourth floor. An amphitheatre is situated in the second story, and there is a dining-room on each floor. The engine- and boiler-room, and also the closets, are in a separate building, entirely disconnected from the hospital proper. The buildings will be heated by steam, well lighted with gas, thoroughly ventilated, and provided with three large elevators. There are three broad oaken staircases. The cost of the hospital will be about $120,000.

—

A Case of Recovery after prolonged Immersion.—Mr. CHAS. POPE gives an account in the *Lancet* for Oct. 1st, of a man who recovered after from twelve to fifteen minutes immersion in water. He was held tightly jammed against a wall by some weight which had capsized his boat, and the reporter attributes his recovery to the fact that this mechanical compression interfered with respiration and thus prevented the filling of the lungs with water.

—

Deliquescent Salts in Street Watering.—The observations of M. Miquel on the constant presence of bacteria—septic, if not pathogenic at all times—in the dust of towns, have recalled attention to the question of the expediency of adding deliquescent salts (if also germicidal, so much the better) to the water used for laying the dust in streets. The idea is not new, the experiment having been made at different times in Glasgow, Paris, and elsewhere, but abandoned for reasons with which we are unacquainted. M. Houzeau, from four years' experience at Rouen, finds that the addition of calcic chloride actually reduces the cost of watering by one-third; for while, under the old system, the operation had to be repeated four times a day, a single watering now sufficed for not less than five or six. The solution employed was the waste liquor from the manufactories of pyroligneous acid, containing, besides calcium chloride, notable quantities of iron and volatile tarry matters also of value as antiseptics. The only reason for its abandonment at Rouen was that improvements in the manufacture of the acid so reduced the strength of the residual liquor that it could no longer be used with advantage commercially. But if the sanitary benefit as well as the comfort of preventing the dispersion of dust were fully realized, no doubt other sources of calcium chloride with the accompanying tar products—as, for example, the manufacture of ammonia from gas liquor—could be found, which would not materially, if at all, increase the cost of street-watering.—*Med. Times and Gaz.*, Oct. 15, 1881.

—

The Bressa Prize.—The Royal Academy of Science of Turin announces that a prize of 12,000 lire (£480), founded by the late Dr. C. A. Bressa, will be given to the competitor who shall, in the opinion of the Academy, have, during the four years 1879–82, made the most important and useful discovery, or produced the best work, in physical and experimental science, natural history, pure and applied mathematics, chemistry, physiology, or pathology, not excluding geology, history, geography, and statistics. Scientific men and inventors of all nations are invited to compete; the only persons excluded being the members of the Academy.—*British Med. Journal*, Oct. 22, 1881.

—

OBITUARY RECORD. — At his residence near Philadelphia, on the 31st of October, 1881, WILLIAM FURNESS JENKS, M.D., aged 39 years.

The death of Dr. Jenks finished a life which a few years ago was full of promise. Educated at Harvard, he received his medical degree from the University of Pennsylvania in 1866, and after a term of service as Resident Physician in the Philadelphia Hospital he studied obstetrics and gynæcology in the special schools

of Berlin, Vienna, London, and Edinburgh. In 1870 he began the practice of his profession in Philadelphia, and lost no time in finding in dispensary service the opportunity of acquiring a practical knowledge of the sciences which he had so carefully studied, and for three years gave a course of practical obstetrics illustrated by operations on the cadaver. For only a few years, however, was he able to continue his work. In the autumn of 1874, failing health compelled him to pass the winter in Florida. On his return, he made an effort to resume work, but was soon forced to give up, and again seek in a foreign climate the health refused him in his own. From this time his professional labours were over, for he saw that the only hope of prolonging his life was in the entire abandonment of all work. For a few years his search for health was partially successful, and he lived in comparative comfort until last October, when after a short confinement in bed he quietly passed away.

Breaking down almost at the beginning of his professional life, Dr. Jenks left but little behind him by which he could be judged, and the full measure of our loss properly estimated. His exhaustive review of Schroeder,[1] and the paper on "Sarcomatous Growths of the Uterus,"[2] bear, however, sufficient evidence of the extent of his knowledge, and of the close analytical character of his mind. A pupil of Sir James Y. Simpson, he regarded the obstetric forceps as extractors, rather than compressors, and after persistent efforts, succeeded in introducing the Simpson Forceps into Philadelphia obstetric practice. A skilful pathologist, he, at the time of his first illness, was preparing a course of lectures on uterine and ovarian pathology for the College of Physicians. Had he been able to complete this course, it would have been a very valuable contribution to this branch of medical science. It, however, was not to be, and when he died, almost nothing remained to his friends, save the recollection of the brilliancy of his genius, his patient industry, and the sparkling geniality of his manner.

—— At his residence near Dublin, on Oct. 21, ALFRED MCCINTOCK, M.D., LL.D., F.R.C.S.I., who is well known in this country as the author of "Clinical Memoirs on the Diseases of Women," and as the editor of Smellie's Midwifery, for the New Sydenham Society.

—— At Paris, October 27, Professor JEAN BAPTISTE BOUILLAUD. Born in 1795, Bouillaud was a young and earnest student when the discovery of auscultation by Laennec gave him the means of making the discovery which will always be connected with his name—the relationship between rheumatism and cardiac disease. He was the author of the word *endocarditis*, and gave an excellent description of the anatomical changes which accompany that disease. In 1831, he obtained, by open competition, the chair of Clinical Medicine at La Charité, where he was an ardent teacher of the doctrine of Broussais, that all diseases were inflammations, and required treatment by bleeding. In 1842 he was returned to the Assembly by his native town, Angoulême, and after the revolution of '48, he was promoted to the post of Dean of the Medical Faculty. He was a member of the Institute and of the Academy of Sciences.

—— At Glasgow, on the 31st of October, DAVID FOULIS, M.D., aged thirty-five. Dr. Foulis was a rising specialist in diseases of the throat, his wide reputation having been achieved by his performing for the first time in England, the operation for the extirpation of the larynx. Dr. Foulis died of diphtheria contracted from a patient on whom he had performed tracheotomy a few days before.

Ziegler, causes of contracted kidney, and the diagnosis of different forms of nephritis, 227

HENRY C. LEA'S SON & CO.'S

(LATE HENRY C. LEA)

CLASSIFIED CATALOGUE

OF

MEDICAL AND SURGICAL PUBLICATIONS.

In asking the attention of the profession to the works advertised in the following pages, the publishers would state that no pains are spared to secure a continuance of the confidence earned for the publications of the house by their careful selection and accuracy and finish of execution.

The large number of inquiries received from the profession for a finer class of bindings than is usually placed on medical books has induced us to put certain of our standard publications in half Russia, and that the growing taste may be encouraged, the prices have been fixed at so small an advance over the cost of sheep, as to place it within the means of all to possess a library that shall have attractions as well for the eye as for the mind of the reading practitioner.

The printed prices are those at which books can generally be supplied by booksellers throughout the United States, who can readily procure for their customers any works not kept in stock. Where access to bookstores is not convenient, books will be sent by mail post-paid on receipt of the price, and as the limit of mailable weight has been removed, no difficulty will be experienced in obtaining through the post-office any work in this catalogue. No risks, however, are assumed either on the money or on the books, and no publications but our own are supplied, so that gentlemen will in most cases find it more convenient to deal with the nearest bookseller.

HENRY C. LEA'S SON & CO.

Nos. 706 and 708 SANSOM ST., PHILADELPHIA, December, 1881.

PROSPECTUS FOR 1882.

A NEW WEEKLY MEDICAL JOURNAL.

SUBSCRIPTION RATES.

THE MEDICAL NEWS, when paid in advance	Five Dollars.
" " " when not paid in advance	Six Dollars.
THE AMERICAN JOURNAL OF THE MEDICAL SCIENCES, strictly in advance	Five Dollars.

COMMUTATION RATES.

THE MEDICAL NEWS THE AMERICAN JOURNAL OF THE MEDICAL SCIENCES	Nine Dollars per annum, in advance.

THE MEDICAL NEWS.

A NATIONAL WEEKLY MEDICAL PERIODICAL, EACH NUMBER CONTAINING FROM 28 TO 32 DOUBLE-COLUMN QUARTO PAGES EXCLUSIVE OF ADVERTISEMENTS.

In these days of rapid thought and quick transmission of intelligence, the profession demand to be supplied with information at more frequent intervals than formerly. In meeting this demand, by converting the "*Medical News and Abstract*" from a monthly to a weekly, the publishers, however, by no means propose to confine themselves to the beaten track, and simply to present another medical weekly of the ordinary character and without distinguishing features. They are convinced that the profession desires to have and will liberally support the best, and the best is only to be obtained by securing the collaboration not of a few men only, or of the men of a single locality, but by uniting the efforts of the ablest minds of the profession throughout the whole continent. The distinguishing characteristic of the "Weekly News," therefore, will be that it will be the mouthpiece or organ not of a single clique or school or city, but of the profession at large, and the promises already received are sufficient to show that with unexampled unanimity the leaders of medical thought everywhere endorse the

project, and pledge their aid to its success. In addition to this the services of a numerous and able editorial corps have been secured, whose care it will be that every department of medical science shall receive due attention and be thoroughly represented in its pages. A periodical so conducted, essentially practical in its character, with the broad and comprehensive scope designed for the "News," becomes a necessity for every practitioner. It is the intention of all concerned that it shall be so, and, therefore, anticipating a circulation unparalleled in medical journalism, an amount of matter will be given in each number which will render it, at the very moderate subscription price of FIVE DOLLARS per annum, the cheapest periodical presented to the profession.

Each number will contain from 28 to 32 large quarto double-column pages of reading matter (exclusive of advertisements), beautifully printed on fine and toned paper, from an exceedingly clear type cast expressly for this purpose. Space will thus be afforded for an immense variety of intelligence, which will be distributed under the following headings:—

ORIGINAL LECTURES, contributed by the most prominent and ablest teachers of the day, will occupy the opening pages. These lectures will be inserted under special arrangement with their authors, and will be invariably revised by them before publication, thus enjoying an accuracy and authenticity impossible to attain by any other method.

This will be followed by a department of ORIGINAL ARTICLES, which will be of a brief and practical nature (the pages of the "*American Journal of the Medical Sciences*" being reserved for articles of a more elaborate character), emanating from the best professional minds of the country, and the same high standard will be observed in their selection which has secured for the "*American Journal*," during the sixty-one years of its uninterrupted publication, the enviable position which it occupies in the medical literature of the world, and which has caused it to be regarded with just pride during this long period by both the profession and its collaborators.

HOSPITAL NOTES will be a feature of the "*Medical News*." It is intended in this department to utilize, for the benefit of the whole profession, the vast and rich stores of clinical experience which accumulate in the hospitals of our country, and which, heretofore, to a large extent, have been lost to the general medical public. In addition to the record of interesting and instructive cases, it is intended to publish from time to time articles showing the local methods and peculiarities of treatment which are practised in the various cities of the Union.

The "PROGRESS OF MEDICAL SCIENCE" will next follow. In this department will be presented, in a condensed form, statements of the advances made in the various branches of medicine and the collateral sciences. For this purpose the columns of all professional periodicals of importance from every quarter of the globe will be carefully scanned and utilized, and from them a *resumé* of whatever may be of interest to the American profession will be presented.

The EDITORIAL DEPARTMENT will form an important feature of the "*News*," to which a liberal allotment of space will be given. In it will be temperately yet firmly discussed the various live questions of the day, affecting the science as well as the profession of medicine; and all mooted points and novel views will receive discussion from a large editorial staff, composed of some of the ablest minds in the profession.

REPORTS OF MEETINGS OF MEDICAL SOCIETIES will follow. In this department will appear authentic abstracts of the proceedings of the prominent medical societies of our country.

Under the head of NEWS ITEMS it is intended to give items of news of general medical interest, and in order that the earliest attainable information on such points may be obtained, an elaborate system of special correspondents is being arranged, not only in the principal cities of the United States, but throughout the civilized world. The very extensive field covered by this system may be appreciated from the fact that arrangements are on foot with gentlemen resident in the following cities. In the UNITED STATES: Boston, New York, Baltimore, Washington, Charleston, New Orleans, St. Louis, Cincinnati, Chicago, Detroit, and San Francisco. In CANADA: Montreal. In ENGLAND: London and Edinburgh. On the CONTINENT OF EUROPE: Paris, Berlin, Vienna, and Florence. In ASIA: Yokohama, Canton, Hong Kong, and Calcutta. In SOUTH AMERICA: Rio Janeiro and Valparaiso. In CUBA: Havana.

New publications, new instruments, and new pharmaceutical preparations will receive due notice, and there will be a column devoted to NOTES AND QUERIES, which it is believed will form a very useful feature to subscribers. In a word, the "*News*" will seek to combine the characteristics of a medical periodical and a professional newspaper; its scope will be cosmopolitan and its character national.

The "*Medical News*" will appear in a double-columned quarto form, printed by the latest improved Hoe presses, on superfine toned paper, from a clear, easily read type

specially cast for its use. As stated above, the subscription price will be FIVE DOLLARS PER ANNUM IN ADVANCE, or when payment is deferred an additional dollar will be asked. At these rates it will rank as the cheapest medical periodical in the world, and when taken in connection with the AMERICAN JOURNAL OF THE MEDICAL SCIENCES, at NINE DOLLARS per annum, it is confidently stated, that a larger amount of material of the highest class is offered than can be obtained elsewhere in the world at even a much higher price.

THE AMERICAN JOURNAL OF THE MEDICAL SCIENCES.

Edited by I. MINIS HAYS, M.D.

For sixty-one years the "*American Journal*" has maintained its position in the front rank of medical literature, and it is with no little pride that, in announcing the opening of the eighty-third volume of the new series, the publishers can state that at no previous time has the outlook for its prosperity been more auspicious. To-day it stands alone as the only periodical in the English language capable of presenting extended and elaborate articles in every branch of medical science, the very class of contributions, in fact, in which nearly all the important discoveries in the science have been communicated to the profession. Its history is identified with that of the advances of medical knowledge, its collaborators include the names of all the most distinguished medical writers of the country, and its circulation is coextensive with the use of the English language.

During the coming year the "Journal" will present in its ORIGINAL DEPARTMENT, a continuation of elaborate articles, from the pens of the most eminent members of the profession throughout the country.

Following this is a REVIEW DEPARTMENT, containing extended reviews of prominent new works and topics of the day by competent writers, together with numerous analytical and bibliographical notices, giving a fairly complete survey of medical literature.

Then follows the QUARTERLY SUMMARY of IMPROVEMENTS and DISCOVERIES in the MEDICAL SCIENCES, classified and arranged under various heads, and furnishing a digest of medical progress, abroad and at home.

The subscription price to the AMERICAN JOURNAL OF THE MEDICAL SCIENCES has never been raised during its long career. It is still sent free of postage for Five Dollars per annum in advance.

Taken together the "Journal" and "News" combine the advantages of the elaborate preparation that can be devoted to a quarterly, with the prompt conveyance of intelligence by the weekly; while, the whole being issued under the same general supervision, the subscriber is by special management secured against the duplication of matter inevitable under other circumstances.

It will thus be seen that for the very moderate sum of NINE DOLLARS in advance the subscriber will receive free of postage a weekly and a quarterly journal, both representing the most advanced condition of the medical sciences, and containing an equivalent of more than 4100 octavo pages, stored with the choicest material, original and selected, that can be furnished by the best medical talent of both hemispheres. It would be impossible to find elsewhere so large an amount of matter of the same value offered at so low a price.

Gentlemen desiring to avail themselves of the advantages thus offered will do well to forward their subscriptions at an early day, in order to insure the receipt of complete sets for 1882.

☞ The safest mode of remittance is by bank check or postal money order, drawn to the order of the undersigned; where these are not accessible remittances for subscriptions may be made at the risk of the publishers by forwarding in *Registered* letters. Address,

HENRY C. LEA'S SON & CO., Nos. 706 and 708 Sansom St., Phila., Pa.

* * * Communications to both these periodicals are invited from gentlemen in all parts of the country. Original articles contributed exclusively to either periodical are liberally paid for upon publication. When necessary to elucidate the text illustrations will be furnished without cost to the author.

All letters pertaining to the *editorial department* of the Medical News and the American Journal of the Medical Sciences should be addressed to the EDITORIAL OFFICES, 1004 Walnut Street, Philadelphia.

All letters pertaining to the *business department* of these journals should be addressed *exclusively* to HENRY C. LEA'S SON & CO., 706 and 708 Sansom Street, Phila.

DUNGLISON (ROBLEY), M.D.,

Late Professor of Institutes of Medicine in Jefferson Medical College, Philadelphia.

MEDICAL LEXICON; A DICTIONARY OF MEDICAL SCIENCE: Containing a concise explanation of the various Subjects and Terms of Anatomy, Physiology, Pathology, Hygiene, Therapeutics, Pharmacology, Pharmacy, Surgery, Obstetrics, Medical Jurisprudence and Dentistry. Notices of Climate and of Mineral Waters; Formulæ for Officinal, Empirical and Dietetic Preparations; with the Accentuation and Etymology of the Terms, and the French and other Synonymes; so as to constitute a French as well as English Medical Lexicon. A New Edition. Thoroughly Revised, and very greatly Modified and Augmented. By RICHARD J. DUNGLISON, M.D. In one very large and handsome royal octavo volume of over 1100 pages. Cloth, $6 50; leather, raised bands, $7 50; half Russia, $8. (*Lately Issued.*)

The object of the author from the outset has not been to make the work a mere lexicon or dictionary of terms, but to afford, under each, a condensed view of its various medical relations, and thus to render the work an epitome of the existing condition of medical science. Starting with this view, the immense demand which has existed for the work has enabled him, in repeated revisions, to augment its completeness and usefulness, until at length it has attained the position of a recognised and standard authority wherever the language is spoken.

Special pains have been taken in the preparation of the present edition to maintain this enviable reputation During the ten years which have elapsed since the last revision, the additions to the nomenclature of the medical sciences have been greater than perhaps in any similar period of the past, and up to the time of his death the author labored assiduously to incorporate everything requiring the attention of the student or practitioner. Since then, the editor has been equally industrious, so that the additions to the vocabulary are more numerous than in any previous revision. Especial attention has been bestowed on the accentuation, which will be found marked on every word. The typographical arrangement has been much improved, rendering reference much more easy, and every care has been taken with the mechanical execution. The work has been printed on new type, small but exceedingly clear, with an enlarged page, so that the additions have been incorporated with an increase of but little over a hundred pages, and the volume now contains the matter of at least four ordinary octavos.

A book well known to our readers, and of which every American ought to be proud. When the learned author of the work passed away, probably all of us feared lest the book should not maintain its place in the advancing science whose terms it defines. Fortunately, Dr. Richard J. Dunglison, having assisted his father in the revision of several editions of the work, and having been, therefore, trained in the methods and imbued with the spirit of the book, has been able to edit it, not in the patchwork manner so dear to the heart of book editors, so repulsive to the taste of intelligent book readers, but to edit it as a work of the kind should be edited—to carry it on steadily, without jar or interruption, along the grooves of thought it has travelled during its lifetime. To show the magnitude of the task which Dr. Dunglison has assumed and carried through, it is only necessary to state that more than six thousand new subjects have been added in the present edition.—*Phila. Med. Times*, Jan. 3, 1874.

About the first book purchased by the medical student is the Medical Dictionary. The lexicon explanatory of technical terms is simply a *sine qua non*. In a science so extensive, and with such collaterals as medicine, it is as much a necessity also to the practising physician. To meet the wants of students and most physicians, the dictionary must be condensed while comprehensive, and practical while perspicacious. It was because Dunglison's met these indications that it became at once the dictionary of general use wherever medicine was studied in the English language. In no former revision have the alterations and additions been so great. More than six thousand new subjects and terms have been added. The chief terms have been set in black letter, while the derivatives follow in small caps; an arrangement which greatly facilitates reference. We may safely confirm the hope ventured by the editor "that the work, which possesses for him a filial as well as an individual interest, will be found worthy a continuance of the position so long accorded to it as a standard authority."—*Cincinnati Clinic*, Jan. 10, 1874.

It has the rare merit that it certainly has no rival in the English language for accuracy and extent of references.—*London Medical Gazette*.

As a standard work of reference, as one of the best, if not the very best, medical dictionary in the English language, Dunglison's work has been well known for about forty years, and needs no words of praise on our part to recommend it to the members of the medical, and, likewise, of the pharmaceutical profession. The latter especially are in need of such a work, which gives ready and reliable information on thousands of subjects and terms which they are liable to encounter in pursuing their daily avocations, but with which they cannot be expected to be familiar. The work before us fully supplies this want.—*Am. Journ. of Pharm.*, Feb. 1874.

A valuable dictionary of the terms employed in medicine and the allied sciences, and of the relations of the subjects treated under each head. It reflects great credit on its able American author, and well deserves the authority and popularity it has obtained.—*British Med. Journ.*, Oct. 31, 1874.

Few works of this class exhibit a grander monument of patient research and of scientific lore. The extent of the sale of this lexicon is sufficient to testify to its usefulness, and to the great service conferred by Dr. Robley Dunglison on the profession, and indeed on others, by its issue.—*London Lancet*, May 18, 1875.

HOBLYN (RICHARD D.), M.D.

A DICTIONARY OF THE TERMS USED IN MEDICINE AND THE COLLATERAL SCIENCES. Revised, with numerous additions, by ISAAC HAYS, M.D., Editor of the "American Journal of the Medical Sciences." In one large royal 12mo. volume of over 500 double-columned pages; cloth, $1 50; leather, $2 00

It is the best book of definitions we have, and ought always to be upon the student's table.—*Southern Med. and Surg. Journal.*

RODWELL (G. F.), F.R.A.S., &c.

A DICTIONARY OF SCIENCE: Comprising Astronomy, Chemistry, Dynamics, Electricity, Heat, Hydrodynamics, Hydrostatics, Light, Magnetism, Mechanics, Meteorology, Pneumatics, Sound and Statics. Preceded by an Essay on the History of the Physical Sciences. In one handsome octavo volume of 694 pages, with many illustrations: cloth, $5.

A CENTURY OF AMERICAN MEDICINE. 1776–1876. By Doctors E. H. Clarke, H. J. Bigelow, S. D. Gross, T. G. Thomas and J. S. Billings. In one very handsome 12mo. volume of about 350 pages: cloth, $2 25.

This work appeared in the pages of the American Journal of the Medical Sciences during the year 1876. As a detailed account of the development of medical science in America, by gentlemen of the highest authority in their respective departments, the profession will no doubt welcome it in a form adapted for preservation and reference.

NEILL (JOHN), M.D., and SMITH (FRANCIS G.), M.D.,
Prof. of the Institutes of Medicine in the Univ. of Penna.

AN ANALYTICAL COMPENDIUM OF THE VARIOUS BRANCHES OF MEDICAL SCIENCE; for the Use and Examination of Students. A new edition, revised and improved. In one very large and handsomely printed royal 12mo. volume, of about one thousand pages, with 374 wood-cuts, cloth, $4; strongly bound in leather, with raised bands, $4 75.

HARTSHORNE (HENRY), M.D.,
Professor of Hygiene in the University of Pennsylvania.

A CONSPECTUS OF THE MEDICAL SCIENCES; containing Handbooks on Anatomy, Physiology, Chemistry, Materia Medica, Practical Medicine, Surgery and Obstetrics. Second Edition, thoroughly revised and improved. In one large royal 12mo. volume of more than 1000 closely printed pages, with 477 illustrations on wood. Cloth, $4 25; leather, $5 00.

We can say with the strictest truth that it is the best work of the kind with which we are acquainted. It embodies in a condensed form all recent contributions to practical medicine, and is therefore useful to every busy practitioner throughout our country, besides being admirably adapted to the use of students of medicine. The book is faithfully and ably executed.—*Charleston Med. Journ.*, April, 1875

The work is intended as an aid to the medical student, and as such appears to admirably fulfil its object by its excellent arrangement, the full compilation of facts, the perspicuity and terseness of language, and the clear and instructive illustrations in some parts of the work.—*American Journ. of Pharmacy*, Philadelphia, July, 1874.

The volume will be found useful, not only to students, but to many others who may desire to refresh their memories with the smallest possible expenditure of time.—*N. Y. Med. Journal*, Sept. 1874.

The student will find this the most convenient and useful book of the kind on which he can lay his hand.—*Pacific Med and Surg. Journ.*, Aug. 1874.

This is the best book of its kind that we have ever examined. It is an honest, accurate, and concise compend of medical sciences, as fairly as possible representing their present condition. The changes and the additions have been so judicious and thorough as to render it, so far as it goes, entirely trustworthy. If students must have a conspectus, they will be wise to procure that of Dr Hartshorne.—*Detroit Rev. of Med. and Pharm.*, Aug. 1874.

The work before us has many redeeming features not possessed by others, and is the best we have seen. Dr. Hartshorne exhibits much skill in condensation. It is well adapted to the physician in active practice, who can give but limited time to the familiarizing of himself with the important changes which have been made since he attended lectures. The manual of physiology has also been improved and gives the most comprehensive view of the latest advances in the science possible in the space devoted to the subject. The mechanical execution of the book leaves nothing to be wished for.—*Peninsular Journal of Medicine*, Sept. 1874.

After carefully looking through this conspectus, we are constrained to say that it is the most complete work, especially in its illustrations, of its kind that we have seen.—*Cincinnati Lancet*, Sept. 1874.

The favor with which the first edition of this Compendium was received, was an evidence of its various excellences. The present edition bears evidence of a careful and thorough revision. Dr. Hartshorne possesses a happy faculty of seizing upon the salient points of each subject, and of presenting them in a concise and yet perspicuous manner.—*Leavenworth Med. Herald*, Oct. 1874

LUDLOW (J. L.), M.D.

A MANUAL OF EXAMINATIONS upon Anatomy, Physiology Surgery, Practice of Medicine, Obstetrics, Materia Medica, Chemistry, Pharmacy and Therapeutics. To which is added a Medical Formulary. Third edition, thoroughly revised and greatly extended and enlarged. With 376 illustrations. In one handsome royal 12mo. volume of 816 large pages. Cloth, $3 25; leather, $3 75.

The arrangement of this volume in the form of question and answer renders it especially suitable for the office examination of students, and for those preparing for graduation.

TANNER (THOMAS HAWKES), M.D., &c.

A MANUAL OF CLINICAL MEDICINE AND PHYSICAL DIAGNOSIS. Third American from the Second London Edition. Revised and Enlarged by TILBURY FOX, M. D., Physician to the Skin Department in University College Hospital, London, &c. In one neat volume, small 12mo., of about 375 pages, cloth, $1 50.

*** On page 3, it will be seen that this work is offered as a premium for procuring new subscribers to the "AMERICAN JOURNAL OF THE MEDICAL SCIENCES."

GRAY (HENRY), F.R.S.,
Lecturer on Anatomy at St. George's Hospital, London.

ANATOMY, DESCRIPTIVE AND SURGICAL. The Drawings by H. V. CARTER, M.D., and Dr. WESTMACOTT. The Dissections jointly by the AUTHOR and Dr. CARTER. With an Introduction on General Anatomy and Development by T. HOLMES, M.A., Surgeon to St. George's Hospital. A new American, from the Eighth enlarged and improved London edition. To which is added the Second American from the latest English Edition of "LANDMARKS, MEDICAL AND SURGICAL," by LUTHER HOLDEN, F.R.C.S., author of "Human Osteology," "A Manual of Dissections," etc. In one magnificent imperial octavo volume of 983 pages, with 522 large and elaborate engravings on wood. Cloth, $6; leather, raised bands, $7; half Russia, $7 50.

The author has endeavored in this work to cover a more extended range of subjects than is customary in the ordinary text-books, by giving not only the details necessary for the student, but also the application of those details in the practice of medicine and surgery, thus rendering it both a guide for the learner, and an admirable work of reference for the active practitioner. The engravings form a special feature in the work, many of them being the size of nature, nearly all original, and having the names of the various parts printed on the body of the cut, in place of figures of reference, with descriptions at the foot. They thus form a complete and splendid series, which will greatly assist the student in obtaining a clear idea of Anatomy, and will also serve to refresh the memory of those who may find in the exigencies of practice the necessity of recalling the details of the dissecting room; while combining, as it does, a complete Atlas of Anatomy, with a thorough treatise on systematic, descriptive and applied Anatomy, the work will be found of essential use to all physicians who receive students in their offices, relieving both preceptor and pupil of much labor in laying the groundwork of a thorough medical education.

Since the appearance of the last American Edition, the work has received three revisions at the hands of its accomplished editor, Mr. Holmes, who has sedulously introduced whatever has seemed requisite to maintain its reputation as a complete and authoritative standard text-book and work of reference. Still further to increase its usefulness, there has been appended to it the recent work by the distinguished anatomist, Mr. Luther Holden—"Landmarks, Medical and Surgical"—which gives in a clear, condensed and systematic way, all the information by which the practitioner can determine from the external surface of the body the position of internal parts. Thus complete, the work, it is believed, will furnish all the assistance that can be rendered by type and illustration in anatomical study. No pains have been spared in the typographical execution of the volume, which will be found in all respects superior to former issues. Notwithstanding the increase of size, amounting to over 100 pages and 57 illustrations, it will be kept, as heretofore, at a price rendering it one of the cheapest works ever offered to the American profession.

The recent work of Mr. Holden, which was noticed by us on p. 53 of this volume, has been added as an appendix, so that, altogether, this is the most practical and complete anatomical treatise available to American students and physicians. The former finds in it the necessary guide in making dissections; a very comprehensive chapter on minute anatomy; and about all that can be taught him on general and special anatomy; while the latter, in its treatment of each region from a surgical point of view, and in the valuable addition of Mr. Holden, will find all that will be essential to him in his practice.—*New Remedies*, Aug 1878.

This work is as near perfection as one could possibly or reasonably expect any book intended as a text-book or a general reference book on anatomy to be. The American publisher deserves the thanks of the profession for appending the recent work of Mr. Holden, "*Landmarks, Medical and Surgical*," which has already been commended as a separate book. The latter work—treating of topographical anatomy—has become an essential to the library of every intelligent practitioner. We know of no book that can take its place, written as it is by a most distinguished anatomist. It would be simply a waste of words to say anything further in praise of Gray's Anatomy, the text-book in almost every medical college in this country, and the daily reference book of every practitioner who has occasion to consult his books on anatomy. The work is simply indispensable especially this present American edition.—*Va. Med. Monthly*, Sept. 1878.

The addition of the recent work of Mr. Holden, as an appendix, renders this the most practical and complete treatise available to American students, who find in it a comprehensive chapter on minute anatomy, about all that can be taught on general and special anatomy, while its treatment of each region, from a surgical point of view, in the valuable section by Mr. Holden, is all that will be essential to them in practice.—*Ohio Medical Recorder*, Aug 1878.

It is difficult to speak in moderate terms of this new edition of "Gray." It seems to be as nearly perfect as it is possible to make a book devoted to any branch of medical science. The labors of the eminent men who have successively revised the eight editions through which it has passed, would seem to leave nothing for future editors to do. The addition of Holden's "Landmarks" will make it as indispensable to the practitioner of medicine and surgery as it has been heretofore to the student. As regards completeness, ease of reference, utility, beauty, and cheapness, it has no rival. No student should enter a medical school without it; no physician can afford to have it absent from his library.—*St. Louis Clin. Record*, Sept. 1878.

ALSO FOR SALE SEPARATE—

HOLDEN (LUTHER), F.R.C.S.,
Surgeon to St. Bartholomew's and the Foundling Hospitals.

LANDMARKS, MEDICAL AND SURGICAL. Second American, from the Latest Revised English Edition, with additions by W. W. KEEN, M.D., Prof. of Artistic Anatomy in the Penna. Academy of the Fine Arts, formerly Lecturer on Anatomy in the Phila. School of Anatomy. In one handsome 12mo. volume, of about 140 pages. Cloth, $1.00. (*Just Ready.*)

HEATH (CHRISTOPHER), F.R.C.S.,
Teacher of Operative Surgery in University College, London.

PRACTICAL ANATOMY: A Manual of Dissections. From the Second revised and improved London edition. Edited, with additions, by W. W. KEEN, M. D., Lecturer on Pathological Anatomy in the Jefferson Medical College, Philadelphia. In one handsome royal 12mo. volume of 578 pages, with 247 illustrations. Cloth, $3 50; leather, $4 00.

ALLEN (HARRISON), M.D.
Professor of Physiology in the Univ. of Pa.

A SYSTEM OF HUMAN ANATOMY: INCLUDING ITS MEDICAL and Surgical Relations. For the Use of Practitioners and Students of Medicine. With an Introductory Chapter on Histology. By E. O. SHAKESPEARE, M D., Ophthalmologist to the Phila. Hosp. In one large and handsome quarto volume, with several hundred original illustrations on lithographic plates, and numerous wood-cuts in the text. (*Shortly.*)

In this elaborate work, which has been in active preparation for several years, the author has sought to give, not only the details of descriptive anatomy in a clear and condensed form, but also the practical applications of the science to medicine and surgery. The work thus has claims upon the attention of the general practitioner, as well as of the student, enabling him not only to refresh his recollections of the dissecting room, but also to recognise the significance of all variations from normal conditions. The marked utility of the object thus sought by the author is self-evident, and his long experience and assiduous devotion to its thorough development are a sufficient guarantee of the manner in which his aims have been carried out. No pains have been spared with the illustrations. Those of normal anatomy are from original dissections, drawn on stone by Mr. Hermann Faber, with the name of every part clearly engraved upon the figure, after the manner of "Holden" and "Gray," and in every typographical detail it will be the effort of the publishers to render the volume worthy of the very distinguished position which is anticipated for it.

ELLIS (GEORGE VINER).
Emeritus Professor of Anatomy in University College, London.

DEMONSTRATIONS OF ANATOMY; Being a Guide to the Knowledge of the Human Body by Dissection. By GEORGE VINER ELLIS, Emeritus Professor of Anatomy in University College, London. From the Eighth and Revised London Edition. In one very handsome octavo volume of over 700 pages, with 256 illustrations. Cloth, $4.25; leather, $5.25. (*Lately Issued.*)

This work has long been known in England as the leading authority on practical anatomy, and the favorite guide in the dissecting-room, as is attested by the numerous editions through which it has passed. In the last revision, which has just appeared in London, the accomplished author has sought to bring it on a level with the most recent advances of science by making the necessary changes in his account of the microscopic structure of the different organs, as developed by the latest researches in textural anatomy.

Ellis's Demonstrations is the favorite text-book of the English student of anatomy. In passing through eight editions it has been so revised and adapted to the needs of the student that it would seem that it had almost reached perfection in this special line. The descriptions are clear, and the methods of pursuing anatomical investigations are given with such detail that the book is honestly entitled to its name.—*St. Louis Clinical Record*, June, 1879.

The success of this old manual seems to be as well deserved in the present as in the past volumes. The book seems destined to maintain yet for years its leadership over the English manuals upon dissecting.—*Phila. Med. Times*, May 24, 1879.

As a dissector, or a work to have in hand and studied while one is engaged in dissecting, we regard it as the very best work extant, which is certainly saying a very great deal. As a text-book to be studied in the dissecting-room, it is superior to any of the works upon anatomy.—*Cincinnati Med. News*, May 24, 1879.

We most unreservedly recommend it to every practitioner of medicine who can possibly get it.—*Va. Med. Monthly*, June, 1879.

WILSON (ERASMUS), F.R.S.

A SYSTEM OF HUMAN ANATOMY, General and Special. Edited by W. H. GOBRECHT, M.D., Professor of General and Surgical Anatomy in the Medical College of Ohio. Illustrated with three hundred and ninety-seven engravings on wood. In one large and handsome octavo volume, of over 600 pages; cloth, $4; leather, $5.

SMITH (HENRY H.), M.D., and *HORNER (WILLIAM E.), M.D.,*
Prof. of Surgery in the Univ. of Penna., &c. — *Late Prof. of Anatomy in the Univ. of Penna.*

AN ANATOMICAL ATLAS; Illustrative of the Structure of the Human Body. In one volume, large imperial octavo, cloth, with about six hundred and fifty beautiful figures. $4 50.

SCHÄFER (EDWARD ALBERT), M.D.,
Assistant Professor of Physiology in University College, London.

A COURSE OF PRACTICAL HISTOLOGY: Being an Introduction to the Use of the Microscope. In one handsome royal 12mo. volume of 304 pages, with numerous illustrations: cloth, $2 00. (*Lately Issued.*)

HORNER'S SPECIAL ANATOMY AND HISTOLOGY. Eighth edition, extensively revised and modified. In 2 vols. 8vo., of over 1000 pages, with 320 wood-cuts: cloth, $6 00.

SHARPEY AND QUAIN'S HUMAN ANATOMY. Revised, by JOSEPH LEIDY, M.D., Prof of Anat. in Univ. of Penn. In two octavo vols. of about 1300 pages, with 511 illustrations Cloth, $6 00.

BELLAMY'S STUDENT'S GUIDE TO SURGICAL ANATOMY: A Text-book for Students preparing for their Pass Examination. With engravings on wood. In one handsome royal 12mo. volume. Cloth, $2 25.

CLELAND'S DIRECTORY FOR THE DISSECTION OF THE HUMAN BODY. In one small volume, royal 12mo. of 182 pages: cloth $1 25.

HARTSHORNE'S HANDBOOK OF ANATOMY AND PHYSIOLOGY. Second edition, revised. In one royal 12mo. vol., with 220 wood cuts; cloth, $1 75.

DALTON (*J. C.*), *M.D.*,

Professor of Physiology in the College of Physicians and Surgeons, New York, &c.

A TREATISE ON HUMAN PHYSIOLOGY. Designed for the use of Students and Practitioners of Medicine. Seventh edition, thoroughly revised and rewritten, with about three hundred and sixty illustrations on wood. In one very beautiful octavo volume, of about 900 pages. (*Nearly Ready.*)

A few notices of the previous edition are appended.

Prof. Dalton has discussed conflicting theories and conclusions regarding physiological questions with a fairness, a fulness, and a conciseness which lend freshness and vigor to the entire book. But his discussions have been so guarded by a refusal of admission to those speculative and theoretical explanations, which at best exist in the minds of observers themselves as only probabilities, that none of his readers need be led into grave errors while making them a study.—*The Medical Record*, Feb. 19, 1876.

For clearness and perspicuity, Dalton's Physiology commended itself to the student years ago, and was a pleasant relief from the verbose productions which it supplanted. Physiology has, however, made many advances since then—and while the style has been preserved intact, the work in the present edition has been brought up fully abreast of the times. The new chemical notation and nomenclature have also been introduced into the present edition. Notwithstanding the multiplicity of text-books on physiology, this will lose none of its old time popularity. The mechanical execution of the work is all that could be desired.—*Peninsular Journal of Medicine*, Dec. 1875.

This popular text-book on physiology comes to us in its sixth edition with the addition of about fifty per cent. of new matter, chiefly in the departments of pathological chemistry and the nervous system, where the principal advances have been realized. With so thorough revision and additions, that keep the work well up to the times, its continued popularity may be confidently predicted, notwithstanding the competition it may encounter. The publisher's work is admirably done.—*St. Louis Med. and Surg. Journ.*, Dec. 1875.

The revision of this great work has brought it forward with the physiological advances of the day, and renders it, as it has ever been, the finest work for students extant.—*Nashville Journ. of Med. and Surg.*, Jan. 1876.

CARPENTER (*WILLIAM B.*), *M. D., F. R. S., F.G.S., F.L.S.*,

Registrar to University of London, &c.

PRINCIPLES OF HUMAN PHYSIOLOGY; Edited by HENRY POWER, M.B. Lond., F.R.C.S., Examiner in Natural Sciences, University of Oxford. A new American from the Eighth Revised and Enlarged English Edition, with Notes and Additions, by FRANCIS G. SMITH, M.D., Professor of the Institutes of Medicine in the University of Pennsylvania, etc. In one very large and handsome octavo volume, of 1083 pages, with two plates and 373 engs. on wood. Cloth, $5 50; leather, $6 50; half Russia, $7.

We have been agreeably surprised to find the volume so complete in regard to the structure and functions of the nervous system in all its relations, a subject that, in many respects, is one of the most difficult of all, in the whole range of physiology, upon which to produce a full and satisfactory treatise of the class to which the one before us belongs. The additions by the American editor give to the work as it is a considerable value beyond that of the last English edition. In conclusion, we can give our cordial recommendation to the work as it now appears. The editors have, with their additions to the only work on physiology in our language that, in the fullest sense of the word, is the production of a philosopher as well as a physiologist, brought it up as fully as could be expected, if not desired, to the standard of our knowledge of its subject at the present day. It will deservedly maintain the place it has always had in the favor of the medical profession.—*Journ. of Nervous and Mental Disease*, April, 1877.

Such enormous advances have recently been made in our physiological knowledge, that what was perfectly new a year or two ago, looks now as if it had been a received and established fact for years. In this encyclopædic way it is unrivalled. Here, as it seems to us, is the great value of the book; one is safe in sending a student to it for information on almost any given subject, perfectly certain of the fulness of information it will convey, and well satisfied of the accuracy with which it will there be found stated.—*London Med. Times and Gazette*, Feb. 17, 1877.

The merits of "Carpenter's Physiology" are so widely known and appreciated that we need only allude briefly to the fact that in the latest edition will be found a comprehensive embodiment of the results of recent physiological investigation. Care has been taken to preserve the practical character of the original work. In fact the entire work has been brought up to date, and bears evidence of the amount of labor that has been bestowed upon it by its distinguished editor, Mr. Henry Power. The American editor has made the latest additions, in order fully to cover the time that has elapsed since the last English edition.—*N. Y. Med. Journal*, Jan. 1877.

FOSTER (*MICHAEL*), *M.D., F.R.S.*,

Prof. of Physiology in Cambridge Univ., England.

TEXT-BOOK OF PHYSIOLOGY. Second American from the Latest English Edition. Edited, with Extensive Notes and Additions, by EDWARD T. REICHERT, M.D., Late Demonstrator of Experimental Therapeutics in the Univ. of Penna. handsome royal 12mo. volume of about 1000 pages, with 260 illustrations. Cloth, $3 25; leather, $3 75. (*Just Ready.*)

In the preparation of a second American edition of Mr. Foster's Physiology, the editor has endeavored to render it more than ever acceptable to the student as a clear and comprehensive text-book, presenting the science in its latest developments. The original work being an exposition of abstract physiology without any reference to the details of physiological anatomy, it seemed desirable to introduce some account of structure, in order to render more intelligible to the student the views and theories of the science. This the editor has added, in as concise a manner as possible; and in aid of this end has freely introduced illustrations from recognized authorities.

LEHMANN'S MANUAL OF CHEMICAL PHYSIOLOGY. Translated from the German, with Notes and Additions, by J. CHESTON MORRIS, M.D. With illustrations on wood. In one octavo volume of 336 pages. Cloth, $2 25.

LEHMANN'S PHYSIOLOGICAL CHEMISTRY. Complete in two large octavo volumes of 1200 pages, with 200 illustrations; cloth, $6.

ATTFIELD (JOHN), Ph.D.,

Professor of Practical Chemistry to the Pharmaceutical Society of Great Britain, &c.

CHEMISTRY, GENERAL, MEDICAL AND PHARMACEUTICAL;

Including the Chemistry of the U. S. Pharmacopœia. A Manual of the General Principles of the Science, and their Application to Medicine and Pharmacy. Eighth edition, revised by the author. In one handsome royal 12mo. volume of 700 pages, with illustrations. Cloth, $2 50; leather, $3 00. (*Now Ready.*)

We have repeatedly expressed our favorable opinion of this work, and on the appearance of a new edition of it, little remains for us to say, except that we expect this eighth edition to be as indispensable to us as the seventh and previous editions have been. While the general plan and arrangement have been adhered to, new matter has been added covering the observations made since the former edition. The present differs from the preceding one chiefly in these alterations and in about ten pages of useful tables added in the appendix.—*Am. Journ. of Pharmacy*, May, 1879.

A standard work like Attfield's Chemistry need only be mentioned by its name, without further comments. The present edition contains such alterations and additions as seemed necessary for the demonstration of the latest developments of chemical principles, and the latest applications of chemistry to pharmacy. The author has bestowed arduous labor on the revision, and the extent of the information thus introduced may be estimated from the fact that the index contains three hundred new references relating to additional material.—*Druggists' Circular and Chemical Gazette*, May, 1879.

This very popular and meritorious work has now reached its eighth edition, which fact speaks in the highest terms in commendation of its excellence. It has now become the principal text-book of chemistry in all the medical colleges in the United States. The present edition contains such alterations and additions as seemed necessary for the demonstration of the latest developments of chemical principles, and the latest applications of chemistry to pharmacy. It is scarcely necessary for us to say that it exhibits chemistry in its present advanced state.—*Cincinnati Medical News*, April, 1879.

The popularity which this work has enjoyed is owing to the original and clear disposition of the facts of the science, the accuracy of the details, and the omission of much which freights many treatises heavily without bringing corresponding instruction to the reader. Dr. Attfield writes for students, and primarily for medical students; he always has an eye to the pharmacopœia and its officinal preparations; and he is continually putting the matter in the text so that it responds to the questions with which each section is provided. Thus the student learns easily, and can always refresh and test his knowledge.—*Med. and Surg. Reporter*, April 19, '79.

We noticed only about two years and a half ago the publication of the preceding edition and remarked upon the exceptionally valuable character of the work. The work now includes the whole of the chemistry of the pharmacopœia of the United States, Great Britain, and India.—*New Remedies*, May, 1879.

GREENE (WILLIAM H.), M.D.,

Demonstrator of Chemistry in Med. Dept., Univ. of Penna.

A MANUAL OF MEDICAL CHEMISTRY. For the Use of Students.

Based upon Bowman's Medical Chemistry. In one royal 12mo. volume of 312 pages With illustrations. Cloth, $1 75. (*Now Ready.*)

is well written, and gives the latest views on vital chemistry, a subject with which most physicians are not sufficiently familiar. To those who may wish to improve their knowledge in that direction, we can heartily recommend this work as being worthy of a careful perusal.—*Phila. Med. and Surg. Reporter*, April 24, 1880.

The little work before us is one which we think will be studied with pleasure and profit. The descriptions, though brief, are clear, and in most cases sufficient for the purpose. This book will, in nearly all cases, meet general approval.—*Am. Journ. of Pharmacy*, April, 1880.

CLASSEN (ALEXANDER),

Professor in the Royal Polytechnic School, Aix-la-Chapelle.

ELEMENTARY QUANTITATIVE ANALYSIS. Translated with

notes and additions by EDGAR F. SMITH, Ph.D., Assistant Prof. of Chemistry in the Towne Scientific School, Univ. of Penna. In one handsome royal 12mo. volume, of 324 pages, with illustrations; cloth, $2 00. (*Lately Issued.*)

It is probably the best manual of an elementary nature extant, inasmuch as its methods are the best. It teaches by examples, commencing with single determinations, followed by separations, and then advancing to the analysis of minerals and such products as are met with in applied chemistry. It is an indispensable book for students in chemistry.—*Boston Journ. of Chemistry*, Oct. 1878.

GALLOWAY (ROBERT), F.C.S.,

Prof. of Applied Chemistry in the Royal College of Science for Ireland, etc.

A MANUAL OF QUALITATIVE ANALYSIS. From the Fifth London Edition.

In one neat royal 12mo. volume, with illustrations; cloth, $2 75.

REMSEN (IRA), M.D., Ph.D.,

Professor of Chemistry in the Johns Hopkins University, Baltimore.

PRINCIPLES OF THEORETICAL CHEMISTRY, with special reference

to the Constitution of Chemical Compounds. In one handsome royal 12mo. vol. of over 232 pages: cloth, $1 50.

BOWMAN'S INTRODUCTION TO PRACTICAL CHEMISTRY, INCLUDING ANALYSIS. Sixth Amer can, from the Sixth and revised London edition. With numerous illustrations. In one neat vol., royal 12mo., cloth, $2 25.

WÖHLER AND FITTIG'S OUTLINES OF ORGANIC CHEMISTRY. Translated, with additions, from the Eighth German Edition. By IRA REMSEN, M.D., Ph.D., Prof. of Chemistry and Physics in Williams College, Mass. In one volume, royal 12mo. of 560 pp., cloth, $3.

FOWNES (GEORGE), Ph.D.

A MANUAL OF ELEMENTARY CHEMISTRY; Theoretical and Practical.

Revised and corrected by HENRY WATTS, B.A., F.R.S., author of "A Dictionary of Chemistry," etc. With a colored plate, and one hundred and seventy-seven illustrations. A new American, from the Twelfth and enlarged London edition. Edited by ROBERT BRIDGES, M.D. In one large royal 12mo. volume, of over 1000 pages; cloth, $2 75; leather, $3 25. (*Lately Issued.*)

This work, inorganic and organic, is complete in one convenient volume. In its earliest editions it was fully up to the latest advancements and theories of that time. In its present form, it presents, in a remarkably convenient and satisfactory manner, the principles and leading facts of the chemistry of *to-day*. Concerning the manner in which the various subjects are treated, much deserves to be said, and mostly, too, in praise of the book. A review of such a work as *Fownes's Chemistry* within the limits of a book-notice for a medical weekly is simply out of the question.—*Cincinnati Lancet and Clinic*, Dec. 14, 1878.

When we state that, in our opinion, the present edition sustains in every respect the high reputation which its predecessors have acquired and enjoyed, we express therewith our full belief in its intrinsic value as a text-book and work of reference.—*Am. Journ. of Pharm.*, Aug. 1878.

The conscientious care which has been bestowed upon it by the American and English editors renders it still, perhaps, the best book for the student and the practitioner who would keep alive the acquisitions of his student days. It has, indeed, reached a somewhat formidable magnitude with its more than a thousand pages, but with less than this no fair representation of chemistry as it now is can be given. The type is small but very clear, and the sections are very lucidly arranged to facilitate study and reference.—*Med and Surg. Reporter*, Aug 3, 1878.

The work is too well known to American students to need any extended notice; suffice it to say that the revision by the English editor has been faithfully done, and that Professor Bridges has added some fresh and valuable matter, especially in the inorganic chemistry. The book has always been a favorite in this country, and in its new shape bids fair to retain all its former *prestige*.—*Boston Jour. of Chemistry*, Aug. 1878.

It will be entirely unnecessary for us to make any remarks relating to the general character of Fownes' Manual. For over twenty years it has held *the* foremost place as a text-book, and the elaborate and thorough revisions which have been made from time to time leave little chance for any wide awake rival to step before it.—*Canadian Pharm. Jour.*, Aug. 1878.

As a manual of chemistry it is without a superior in the language.—*Md. Med. Jour.*, Aug. 1878.

BLOXAM (C. L.),

Professor of Chemistry in King's College, London.

CHEMISTRY, INORGANIC AND ORGANIC.

From the Second London Edition. In one very handsome octavo volume, of 700 pages, with about 300 illustrations. Cloth, $4 00; leather, $5 00.

We have in this work a complete and most excellent text-book for the use of schools, and can heartily recommend it as such.—*Boston Med. and Surg. Journ.*, May 28, 1874.

The above is the title of a work which we can most conscientiously recommend to students of chemistry. It is as easy as a work on chemistry could be made, at the same time that it presents a full account of that science as it now stands. We have spoken of the work as admirably adapted to the wants of students; it is quite as well suited to the requirements of practitioners who wish to review their chemistry, or have occasion to refresh their memories on any point relating to it. In a word, it is a book to be read by all who wish to know what is the chemistry of the present day.—*American Practitioner*, Nov. 1873.

It would be difficult for a practical chemist and teacher to find any material fault with this most admirable treatise. The author has given us almost a cyclopædia within the limits of a convenient volume, and has done so without penning the *useless* paragraphs too commonly making up a great part of the bulk of many cumbrous works. The progressive scientist is not disappointed when he looks for the record of new and valuable processes and discoveries; while the cautious conservative does not find its pages monopolized by uncertain theories and speculations. A peculiar point of excellence is the crystallized form of expression in which great truths are expressed in very short paragraphs. One is surprised at the brief space allotted to an important topic, and yet, after reading it, he feels that little, if any more should have been said. Altogether, it is seldom you see a text-book so nearly faultless.—*Cincinnati Lancet*, Nov. 1873.

CLOWES (FRANK), D.Sc., London.

Senior Science-Master at the High School, Newcastle-under-Lyme, etc.

AN ELEMENTARY TREATISE ON PRACTICAL CHEMISTRY AND QUALITATIVE INORGANIC ANALYSIS.

Specially adapted for Use in the Laboratories of Schools and Colleges and by Beginners. Second American from the Third and Revised English Edition. In one very handsome royal 12mo. volume of 372 pages, with 47 illustrations. Cloth, $2 50. (*Just Ready.*)

This is a valuable work for those about to commence chemistry, the more so as by its use they are simultaneously acquainted with the manipulation of chemical analysis, a method which is the most valuable to impart a thorough knowledge of chemistry. It is a very good little book, and will make for itself many warm friends and supporters. It treats the subject well and the tables are very clear and valuable.—*St. Louis Med. and Surg. Journ.*, Mar. 1881.

This work is not only well adapted for use as a text-book in medical colleges, but is also one of the best that a practitioner can have for convenient reference and instruction in his library. As a rule, such volumes are too technical and abstruse for study without some didactic aid, but the volume presented is easy of comprehension, and will be of great value to college students and busy practitioners.—*N. Y. Am. Med. Bi-Weekly*, April 9, 1881.

The tables particularly demand praise, for they are admirably formed, both for convenience of reference and fulness of information. In short, we do not remember to have met with a book which could better serve the student as a guide to the systematic study of inorganic chemistry.—*Louisville Med. News*, March 12, 1881.

KNAPP'S TECHNOLOGY; or Chemistry Applied to the Arts and to Manufactures. With American additions by Prof. WALTER R. JOHNSON. In two very handsome octavo volumes, with 500 wood engravings, cloth, $6 00.

HOFFMAN (FRED.), Ph.D. and, POWER (FRED. B.), Ph.D.,

Prof. of Anal. Chem. in Phil. Coll. of Pharmacy.

MANUAL OF CHEMICAL ANALYSIS, as Applied to the Examination of Medical Chemicals and their Preparations.

Being a Guide for the Determination of their Identity and Quality, and for the Detection of Impurities and Adulterations. For the Use of Pharmacists, Physicians, Druggists and Manufacturing Chemists, and Pharmaceutical and Medical Students. Third edition, entirely rewritten and much enlarged. In one very handsome octavo volume, fully illustrated. (*Preparing.*)

PARRISH (EDWARD),

Late Professor of Materia Medica in the Philadelphia College of Pharmacy.

A TREATISE ON PHARMACY.

Designed as a Text-Book for the Student, and as a Guide for the Physician and Pharmaceutist. With many Formulæ and Prescriptions. Fourth Edition, thoroughly revised, by THOMAS S. WIEGAND. In one handsome octavo volume of 977 pages, with 280 illustrations; cloth, $5 50; leather, $6 50; half Russia, $7

Of Dr. Parrish's great work on pharmacy it only remains to be said that the editor has accomplished his work so well as to maintain, in this fourth edition, the high standard of excellence which it had attained in previous editions, under the editorship of its accomplished author. This has not been accomplished without much labor, and many additions and improvements, involving changes in the arrangement of the several parts of the work, and the addition of much new matter. With the modifications thus effected it constitutes, as now presented, a compendium of the science and art indispensable to the pharmacist, and of the utmost value to every practitioner of medicine desirous of familiarizing himself with the pharmaceutical preparation of the articles which he prescribes for his patients.—*Chicago Med. Journ.*, July, 1874.

The work is eminently practical, and has the rare merit of being readable and interesting, while it preserves a strictly scientific character. The whole work reflects the greatest credit on author, editor and publisher. It will convey some idea of the liberality which has been bestowed upon its production when we mention that there are no less than 280 carefully executed illustrations. In conclusion, we heartily recommend the work, not only to pharmacists, but also to the multitude of medical practitioners who are obliged to compound their own medicines. It will ever hold an honored place on our own bookshelves.—*Dublin Med. Press and Circular*, Aug. 12, 1874.

Perhaps one, if not the most important book upon pharmacy which has appeared in the English language has emanated from the transatlantic press. "Parrish's Pharmacy" is a well-known work on this side of the water, and the fact shows us that a really useful work never becomes merely local in its fame. Thanks to the judicious editing of Mr. Wiegand, the posthumous edition of "Parrish" has been saved to the public with all the mature experience of its author, and perhaps none the worse for a dash of new blood.—*Lond. Pharm. Journal*, Oct. 17, 1874.

GRIFFITH (ROBERT E.), M.D.

A UNIVERSAL FORMULARY, Containing the Methods of Preparing and Administering Officinal and other Medicines.

The whole adapted to Physicians and Pharmaceutists. Third edition, thoroughly revised, with numerous additions, by JOHN M. MAISCH, Professor of Materia Medica in the Philadelphia College of Pharmacy. In one large and handsome octavo volume of about 800 pages. Cloth, $4 50; leather, $5 50.

A more complete formulary than it is in its present form the pharmacist or physician could hardly desire. To the first some such work is indispensable, and it is hardly less essential to the practitioner who compounds his own medicines. Much of what is contained in the introduction ought to be committed to memory by every student of medicine. As a help to physicians it will be found invaluable, and doubtless will make its way into libraries not already supplied with a standard work of the kind.—*The American Practitioner*, Louisville, July, '74.

FARQUHARSON (ROBERT), M.D.,

Lecturer on Materia Medica at St. Mary's Hospital Medical School.

A GUIDE TO THERAPEUTICS AND MATERIA MEDICA.

Second American edition, revised by the Author. Enlarged and adapted to the U. S. Pharmacopœia. By FRANK WOODBURY, M.D. In one neat royal 12mo. volume of 498 pages: cloth, $2.25. (*Lately Issued.*)

The appearance of a new edition of this convenient and handy book in less than two years may certainly be taken as an indication of its usefulness. Its convenient arrangement, and its terseness, and, at the same time, completeness of the information given, make it a handy book of reference.—*Am. Journ. of Pharmacy*, June, 1879.

This work contains in moderate compass such well-digested facts concerning the physiological and therapeutical action of remedies as are reasonably established up to the present time. By a convenient arrangement the corresponding effects of each article in health and disease are presented in parallel columns, not only rendering reference easier, but also impressing the facts more strongly upon the mind of the reader. The book has been adapted to the wants of the American student, and copious notes have been introduced, embodying the latest revision of the Pharmacopœia, together with the antidotes to the more prominent poisons, and such of the newer remedial agents as seemed necessary to the completeness of the work. Tables of weights and measures, and a good alphabetical index end the volume.—*Druggists' Circular and Chemical Gazette*, June, 1879.

It is a pleasure to think that the rapidity with which a second edition is demanded may be taken as an indication that the sense of appreciation of the value of reliable information regarding the use of remedies is not entirely overwhelmed in the cultivation of pathological studies, characteristic of the present day. This work certainly merits the success it has so quickly achieved.—*New Remedies*, July, '79.

CHRISTISON'S DISPENSATORY. With copious additions, and 213 large wood engravings. By R. EGLESFELD GRIFFITH, M.D. One vol. 8vo., pp. 1000, cloth, $4 00.

CARPENTER'S PRIZE ESSAY ON THE USE OF ALCOHOLIC LIQUORS IN HEALTH AND DISEASE. New edition, with a Preface by D. F. CONDIE, M.D., and explanations of scientific words. In one neat 18mo. volume, pp. 178, cloth, 60 cents.

STILLÉ (*ALFRED*), *M. D., LL.D., and* MAISCH (*JOHN M.*), *Ph.D.*,
Prof. of Theory and Practice of Medicine and of Clinical Med. in Univ. of Pa. — *Prof. of Mat. Med. and Hot. in Phila. Coll. Pharmacy, Secy. to the American Pharmaceutical Association.*

THE NATIONAL DISPENSATORY: Containing the Natural History, Chemistry, Pharmacy, Actions and Uses of Medicines, including those recognised in the Pharmacopœias of the United States, Great Britain and Germany, with numerous references to the French Codex. Second edition, thoroughly revised, with numerous additions. In one very handsome octavo volume of 1692 pages, with 239 illustrations. Extra cloth, $6 75; leather, raised bands, $7 50; half Russia, raised bands and open back, $8 25. (*Now Ready.*)

PREFACE TO THE SECOND EDITION.

The demand which has exhausted in a few months an unusually large edition of the National Dispensatory is doubly gratifying to the authors, as showing that they were correct in thinking that the want of such a work was felt by the medical and pharmaceutical professions, and that their efforts to supply that want have been acceptable. This appreciation of their labors has stimulated them in the revision to render the volume more worthy of the very marked favor with which it has been received. The first edition of a work of such magnitude must necessarily be more or less imperfect; and though but little that is new and important has been brought to light in the short interval since its publication, yet the length of time during which it was passing through the press rendered the earlier portions more in arrears than the later. The opportunity for a revision has enabled the authors to scrutinize the work as a whole, and to introduce alterations and additions wherever there has seemed to be occasion for improvement or greater completeness. The principal changes to be noted are the introduction of several drugs under separate headings, and of a large number of drugs, chemicals and pharmaceutical preparations classified as allied drugs and preparations under the heading of more important or better known articles; these additions comprise in part nearly the entire German Pharmacopœia and numerous articles from the French Codex. All new investigations which came to the authors' notice up to the time of publication have received due consideration.

The series of illustrations has undergone a corresponding thorough revision. A number have been added, and still more have been substituted for such as were deemed less satisfactory.

The new matter embraced in the text is equal to nearly one hundred pages of the first edition. Considerable as are these changes as a whole, they have been accommodated by an enlargement of the page without increasing unduly the size of the volume.

While numerous additions have been made to the sections which relate to the physiological action of medicines and their use in the treatment of disease, great care has been taken to make them as concise as was possible without rendering them incomplete or obscure. The doses have been expressed in the terms both of troy weight and of the metrical system, for the purpose of making those who employ the Dispensatory familiar with the latter, and paving the way for its introduction into general use.

The Therapeutical Index has been extended by about 2250 new references, making the total number in the present edition about 6000.

The articles there enumerated as remedies for particular diseases are not only those which, in the authors' opinion, are curative, or even beneficial, but those also which have at any time been employed on the ground of popular belief or professional authority. It is often of as much consequence to be acquainted with the worthlessness of certain medicines or with the narrow limits of their power, as to know the well attested virtues of others and the conditions under which they are displayed. An additional value possessed by such an Index is, that it contains the elements of a natural classification of medicines, founded upon an analysis of the results of experience, which is the only safe guide in the treatment of disease.

This evidence of success, seldom paralleled, shows clearly how well the authors have met the existing needs of the pharmaceutical and medical professions. Gratifying as it must be to them, they have embraced the opportunity offered for a thorough revision of the whole work, striving to embrace within it all that might have been omitted in the former edition, and all that has newly appeared of sufficient importance during the time of its collaboration, and the short interval elapsed since the previous publication. After having gone carefully through the volume we must admit that the authors have labored faithfully, and with success, in maintaining the high character of their work as a compendium meeting the requirements of the day, to which one can safely turn in quest of the latest information concerning everything worthy of notice in connection with Pharmacy, Materia Medica, and Therapeutics.—*Am. Jour. of Pharmacy*, Nov. 1879.

It is with great pleasure that we announce to our readers the appearance of a *second* edition of the National Dispensatory. The total exhaustion of the first edition in the short space of six months, is a sufficient testimony to the value placed upon the work by the profession. It appears that the rapid sale of the first edition must have induced both the editors and the publisher to make preparations for a new edition immediately after the first had been issued, for we find a large amount of new matter added and a good deal of the previous text altered and improved, which proves that the authors do not intend to let the grass grow under their feet, but to keep the work up to the time.—*New Remedies*, Nov. 1879.

This is a great work by two of the ablest writers on materia medica in America. The authors have produced a work which, for accuracy and comprehensiveness, is unsurpassed by any work on the subject. There is no book in the English language which contains so much valuable information on the various articles of the materia medica. The work has cost the authors years of laborious study, but they have succeeded in producing a dispensatory which is not only *national*, but will be a lasting memorial of the learning and ability of the authors who produced it.—*Edinburgh Medical Journal*, Nov. 1879.

It is by far more international or universal than any other book of the kind in our language, and more comprehensive in every sense.—*Pacific Med. and Surg. Journ.*, Oct. 1879.

The National Dispensatory is beyond dispute the very best authority. It is throughout complete in all the necessary details, clear and lucid in its explanations, and replete with references to the most recent writings, where further particulars can be obtained, if desired. Its value is greatly enhanced by the extensive indices—a general index of materia medica, etc., and also an index of therapeutics. It would be a work of supererogation to say more about this well-known work. No practising physician can afford to be without the National Dispensatory.—*Canada Med. and Surg. Journ.*, Feb. 1880.

MAISCH (JOHN M.), Phar. D.,

Prof. of Materia Medica and Botany in the Phila. Coll. of Pharmacy.

A MANUAL OF ORGANIC MATERIA MEDICA.

Being a Guide to Materia Medica of the Vegetable and Animal Kingdoms. For the use of Students, Druggists, Pharmacists and Physicians. In one handsome 12mo. volume, with numerous illustrations on wood. (*Preparing.*)

EXTRACT FROM THE AUTHOR'S PREFACE.

When in 1866 the author was called to the chair of Materia Medica in the institution named (the Philadelphia College of Pharmacy), he seriously felt the need of a suitable text book which could be used in connection with his lectures, and made preparations for the publication of such a work at an early date To elaborate a system of classification, which should be without difficulty comprehended and readily applied by those for whom it was intended, was by no means an easy task, and the author found occasion, almost every year, to either remodel that previously selected, or to make what in his opinion seemed to be desirable improvements. The publication of the "National Dispensatory" in a measure supplied the want felt, at least as far as a work of reference is concerned but owing to its local arrangement, it is not adapted to systematic instruction. However, its publication rendered a modification of the original plan for a treatise on Materia Medica desirable, and it is now presented in a form giving an outline of the substance of the lectures and embracing what are considered the essential physical, histological, and chemical characters of the organic drug, so as to render the work also a useful and reliable guide in business transactions. Regarding the classification, the author is conscious of its imperfections, but he believes it to be convenient and capable of practical application.

In reference to the scope of the work, the main aim has been to embrace all the drugs recognized by the U. S. Pharmacopœia, together with the old, but now unofficinal ones, and such others, the use of which has been recently revived or suggested, and which seem to deserve attention. The medical properties and doses of the various drugs are merely briefly stated as subjects of general important information; the present work is not intended for giving instruction in the therapeutic application of drugs.

STILLÉ (ALFRED), M. D.,

Professor of Theory and Practice of Medicine in the University of Penna.

THERAPEUTICS AND MATERIA MEDICA; a Systematic Treatise

on the Action and Uses of Medicinal Agents, including their Description and History. Fourth edition, revised and enlarged. In two large and handsome 8vo. vols. of about 2000 pages. Cloth, $10; leather, $12; half Russia, $13.

It is unnecessary to do much more than to announce the appearance of the fourth edition of this well known and excellent work.—*Brit. and For. Med.-Chir. Review*, Oct 1875.

For all who desire a complete work on therapeutics and materia medica for reference, in cases involving medico-legal questions, as well as for information concerning remedial agents. Dr Stillé's is "*par excellence*" the work Being out of print, by the exhaustion of former editions, the author has laid the profession under renewed obligations, by the careful revision, important additions, and timely reissuing a work not exactly supplemented by any other in the English language, if in any language. The mechanical execution handsomely sustains the well-known skill and good taste of the publisher.—*St. Louis Med. and Surg. Journal*, Dec 1874.

From the publication of the first edition "Stillé's Therapeutics" has been one of the classics; its absence from our libraries would create a vacuum which could be filled by no other work in the language, and its presence supplies, in the two volumes of the present edition, a whole cyclopædia of therapeutics.—*Chicago Medical Journal*, Feb. 1875.

The rapid exhaustion of three editions and the universal favor with which the work has been received by the medical profession, are sufficient proof of its excellence as a repertory of practical and useful information for the physician. The edition before us fully sustains this verdict, as the work has been carefully revised and in some portions rewritten, bringing it up to the present time by the admission of chloral and croton chloral nitrite of amyl, bichloride of methylene, methylic ether, lithium compounds, gelseminum, and other remedies.—*Am. Journ of Pharmacy*, Feb. 1875.

We can hardly admit that it has a rival in the multitude of its citations and the fulness of its research into clinical histories, and we must assign it a place in the physician's library; not, indeed, as fully representing the present state of knowledge in pharmacodynamics, but as by far the most complete treatise upon the clinical and practical side of the question.—*Boston Med. and Surg. Journal*, Nov. 5, 1874.

CORNIL (V.), Prof. in the Faculty of Med., Paris AND RANVIER (L.), Prof. in the College of France.

MANUAL OF PATHOLOGICAL HISTOLOGY.

Translated, with Notes and Additions, by E. O. SHAKESPEARE, M.D., Pathologist and Ophthalmic Surgeon to Philada Hospital, Lecturer on Refraction and Operative Ophthalmic Surgery in Univ. of Penna., and by HENRY C. SIMES M.D., Demonstrator of Pathological Histology in the Univ. of Pa. In one very handsome octavo volume of over 700 pages, with over 350 illustrations. Cloth, $5 50; leather, $6 50; half Russia, $7. (*Just Ready.*)

We have no hesitation in cordially recommending the English translation of Cornil & Ranvier's "Pathological Histology" as the best work of the kind in any language, and as giving to its readers a trustworthy guide in obtaining a broad and solid basis for the appreciation of the practical bearings of pathological anatomy.—*Am. Journ. of Med. Sciences*, April, 1870.

This important work, in its American dress, is a welcome offering to all students of the subjects which it treats. The great mass of material is arranged naturally and comprehensively. The classification of tumors is clear and full, so far as the subject admits of definition, and this one chapter is worth the price of the book The illustrations are copious and well chosen. Without the slightest hesitation, the translators deserve honest thanks for placing this indispensable work in the hands of American students.—*Phila. Med. Times*, April 24, 1870

This volume we cordially commend to the profession. It will prove a valuable, almost necessary, addition to the libraries of students who are to be physicians, and to the libraries of students who are physicians.—*American Practitioner*, June, 1870.

FENWICK (SAMUEL), M.D.,
Assistant Physician to the London Hospital.

THE STUDENT'S GUIDE TO MEDICAL DIAGNOSIS.

From the Third Revised and Enlarged English Edition. With eighty-four illustrations on wood. In one very handsome volume, royal 12mo., cloth, $2 25. (*Lately Issued.*)

GREEN (T. HENRY), M.D.,
Lecturer on Pathology and Morbid Anatomy at Charing-Cross Hospital Medical School, etc.

PATHOLOGY AND MORBID ANATOMY.

Fourth American, from the Fifth Enlarged and Revised English Edition. In one very handsome octavo volume of about 350 pages, with 138 fine engravings; cloth, $2 25. (*Just Ready.*)

EXTRACT FROM THE AUTHOR'S PREFACE.

In preparing the fifth edition of my Text-book on Pathology and Morbid Anatomy, I have again added much new matter, with the object of making the work a more complete guide for the student. All the chapters have been carefully revised, some alterations have been made in the arrangement of the work, and an addition has been made to the number of wood-cuts. The new wood-cuts, as in previous editions, have been drawn by Mr. Collings from my own microscopical preparations.

We have long considered this the best guide yet presented to the student for the identification of various morbid tissues. We have found it more satisfactory than any other. The present edition has been thoroughly revised, and much new matter has been added. To the physician as a guide in diagnosis, we recommend this volume.—*Physician and Surgeon*, May, 1881.

BRISTOWE (JOHN SYER), M.D., F.R.C.P.,
Physician and Joint Lecturer on Medicine, St. Thomas's Hospital.

A TREATISE ON THE PRACTICE OF MEDICINE.

Second American edition, revised by the Author. Edited, with Additions, by JAMES H. HUTCHINSON, M.D., Physician to the Penna. Hospital. In one handsome octavo volume of nearly 1200 pages. With illustrations. Cloth, $5 00; leather, $6 00; half Russia, $6 50. (*Now Ready.*)

The second edition of this excellent work, like the first, has received the benefit of Dr. Hutchinson's annotations, by which the phases of disease which are peculiar to this country are indicated, and thus a treatise which was intended for British practitioners and students is made more practically useful on this side of the water. We see no reason to modify the high opinion previously expressed with regard to Dr. Bristowe's work, except by adding our appreciation of the careful labors of the author in following the lateral growth of medical science.—*Boston Medical and Surgical Journal*, February, 1880.

What we said of the first edition, we can, with increased emphasis, repeat concerning this: "Every page is characterized by the utterances of a thoughtful man. What has been well said, has been well said, and the book is a fair reflex of all that is *certainly known* on the subjects considered."—*Ohio Med Recorder*, Jan. 7, 1880.

The views of the author are expressed with precision and sufficient promptness to impress the student with the weight of his authority; and should the medical professor differ on any subject from his doctrine, he will need to find strong arguments to carry his class to the opposite conclusion.—*N. O. Med. and Surg. Journ.*, Feb. 1880.

The reader will find every conceivable subject connected with the practice of medicine ably presented, in a style at once clear, interesting, and concise. The additions made by Dr. Hutchinson are appropriate and practical, and greatly add to its usefulness to American readers.—*Buffalo Med. and Surg. Journ.*, March, 1880.

We regard it as an excellent work for students and for practitioners. It is clearly written, the author's style is attractive, and it is especially to be commended for its excellent exposition of the pathology and clinical phenomena of disease.—*St. Louis Clin. Record*, Feb. 1880.

HABERSHON (S. O.), M.D.
Senior Physician to, and late Lecturer on the Principles and Practice of Medicine at, Guy's Hospital, etc.

ON THE DISEASES OF THE ABDOMEN, COMPRISING THOSE

of the Stomach, and other parts of the Alimentary Canal, Œsophagus, Cæcum, Intestines and Peritoneum. Second American, from the Third enlarged and revised English edition. With illustrations. In one handsome octavo volume of over 500 pages. Cloth, $3 50. (*Lately Issued.*)

This valuable treatise on diseases of the stomach and abdomen has been out of print for several years, and is therefore not so well known to the profession as it deserves to be. It will be found a cyclopædia of information, systematically arranged, on all diseases of the alimentary tract, from the mouth to the rectum. A fair proportion of each chapter is devoted to symptoms, pathology, and therapeutics. The present edition is fuller than former ones in many particulars, and has been thoroughly revised and amended by the author. Several new chapters have been added, bringing the work fully up to the times, and making it a volume of interest to the practitioner in every field of medicine and surgery. Perverted nutrition is in some form associated with all diseases we have to combat, and we need all the light that can be obtained on a subject so broad and general. Dr Habershon's work is one that every practitioner should read and study for himself.—*N. Y. Med. Journ.*, April, 1879.

GLUGE'S ATLAS OF PATHOLOGICAL HISTOLOGY. Translated, with Notes and Additions, by JOSEPH LEIDY, M. D. In one volume, very large imperial quarto, with 320 copper-plate figures, plain and colored, cloth. $4 00

LA ROCHE ON YELLOW FEVER, considered in its Historical, Pathological, Etiological and Therapeutical Relations. In two large and handsome octavo volumes of nearly 1500 pp., cloth. $7 00.

STOKES' LECTURES ON FEVER. Edited by JOHN WILLIAM MOORE, M.D., Assistant Physician to the Cork Street Fever Hospital. In one neat 8vo volume cloth, $2 00.

PAVY'S TREATISE ON THE FUNCTION OF DIGESTION: its Disorders and their Treatment. From the Second London edition. In one handsome volume, small octavo, cloth, $2 00.

HOLLAND'S MEDICAL NOTES AND REFLECTIONS. 1 vol. 8vo., pp. 500, cloth. $3 50

BARLOW'S MANUAL OF THE PRACTICE OF MEDICINE. With Additions by D. F. CONDIE, M.D. 1 vol. 8vo., pp. 600, cloth. $3 50

TODD'S CLINICAL LECTURES ON CERTAIN ACUTE DISEASES. In one neat octavo volume, of 320 pp. cloth. $2 50.

FLINT (AUSTIN), M.D.,

Professor of the Principles and Practice of Medicine in Bellevue Med. College, N. Y.

A TREATISE ON THE PRINCIPLES AND PRACTICE OF MEDICINE; designed for the use of Students and Practitioners of Medicine. Fifth edition, entirely rewritten and much improved. In one large and closely printed octavo volume of 1153 pp. Cloth, $5 50; leather, $6 50; very handsome half Russia, raised bands, $7. (*Just Ready.*)

This work has been so long and favorably known, and has obtained so high a position amongst modern treatises on medicine, that it is hardly necessary to do more than announce the publication of this fifth edition. All who peruse it must be struck by the extensive research which has been undertaken in the revision of this edition, combined with much original thought. There is hardly a subject which does not receive fresh illustration and discussion, opening up new lines of inquiry which had not been thought of when the previous edition appeared. We cannot conclude this notice without expressing our admiration of this volume, which is certainly one of the standard text-books on medicine, and we may safely affirm that, taken altogether, it exhibits a fuller and wider acquaintance with recent pathological inquiry than any similar work with which we are acquainted, whilst at the same time it shows its author to be possessed of the rare faculties of clear exposition, thoughtful discrimination, and sound judgment.—*London Lancet*, July 23, 1881.

Practically, this edition is a new work; for so many additions and changes have been made that one well acquainted with previous editions would hardly recognize this as an old friend. The size of the volume is somewhat increased. An entire new section and several new chapters have been added. It is universally conceded that no text book upon this subject was ever published in this country that can at all compare with it. It has long been at the very head of American text-book literature, and there can be no doubt but that it will be many years before it yields the place to others.—*Nashville Journ. of Med. and Surg.*, Feb. 1881.

"Flint's Practice" is recognized to be a standard treatise of high rank upon the principles and the practice of medicine wherever the English language is read. The opinions everywhere reveal the man of extensive experience, diligent study, calm judgment, and unbiassed criticism. The work should be in the hands of every practitioner.—*New York Med. Record*, Feb. 26, 1881.

The style and character of this work are too well known to the profession to require an introduction. For a number of years this volume has occupied a leading position as a text-book in the majority of medical schools, and the high position accorded to it in the past is a guarantee of a hearty welcome in this new edition. The book may be said to represent the present state of the science of medicine as now understood and taught. It is a safe guide to students and practitioners of medicine.—*Maryland Medical Journal*, March 1, 1881.

The author has, in this edition, revised and rewritten a great part and made it accord with the more advanced ideas which have been developed within the past few years. He is the more fitted to do so, as he is actively engaged in his profession, and can make deductions, not from the work of others, but from his own labors. It is a treatise which every American physician should have upon his table, and which he should consult on occasions when his leisure permits him to do so.—*St. Louis Med. and Surg. Journal*, March, 1881.

BY THE SAME AUTHOR.

CLINICAL MEDICINE; a Systematic Treatise on the Diagnosis and Treatment of Diseases. Designed for Students and Practitioners of Medicine. In one large and handsome octavo volume of 795 pages; cloth, $4 50; leather, $5 50; half Russia, $6. (*Now Ready*)

The eminent teacher who has written the volume under consideration has recognized the needs of the American profession, and the result is all that we could wish. The style in which it is written is peculiarly the author's; it is clear and forcible, and marked by those characteristics which have rendered him one of the best writers and teachers this country has ever produced. We have not space for so full a consideration of this remarkable work as we would desire.—*St. Louis Clin. Record*, Oct. 1879.

It is here that the skill and learning of the great clinician are displayed. He has given us a storehouse of medical knowledge, excellent for the student, convenient for the practitioner, the result of a long life of the most faithful clinical work, collected by an energy as vigilant and systematic as untiring, and weighed by a judgment no less clear than his observation is close.—*Archives of Medicine*, Dec. 1879.

To give an adequate and useful conspectus of the extensive field of modern clinical medicine is a task of no ordinary difficulty; but to accomplish this consistently, with brevity and clearness, the different subjects and their several parts receiving the attention which, relatively to their importance, medical opinion claims for them, is still more difficult. This task we feel bound to say has been executed with more than partial success by Dr Flint, whose name is already familiar to students of advanced medicine in this country as that of the author of two works of great merit on special subjects, and of numerous papers, exhibiting much originality and extensive research.—*The Dublin Journal*, Dec. 1879.

There is every reason to believe that this book will be well received. The active practitioner is frequently in need of some work that will enable him to obtain information in the diagnosis and treatment of cases with comparatively little labor. Dr. Flint has the faculty of expressing himself clearly, and at the same time so concisely as to enable the searcher to traverse the entire ground of his search, and at the same time obtain all that is essential, without plodding through an interminable space.—*N. Y. Med. Journ.*, Nov. 1879.

The great object is to place before the reader the latest observations and experience in diagnosis and treatment. Such a work is especially valuable to students. It is complete in its special design, and yet so condensed, that he can by its aid, keep up with the lectures on practice without neglecting other branches. It will not escape the notice of the practitioner that such a work is most valuable in culling points in diagnosis and treatment in the intervals between the daily rounds of visits, since he can in a few minutes refresh his memory, or learn the latest advance in the treatment of diseases which demand his instant attention.—*Cincinnati Lancet and Clinic*, Oct. 25, 1879.

PREVENTIVE MEDICINE. In one octavo volume of about 500 pages. (*Shortly.*)

HARTSHORNE (HENRY), M.D.,
Professor of Hygiene in the University of Pennsylvania

ESSENTIALS OF THE PRINCIPLES AND PRACTICE OF MEDICINE. A handy book for Students and Practitioners Fifth edition, thoroughly revised and rewritten. With 140 illustrations. In one handsome royal 12mo. volume, of about 600 pages. (*In Press.*)

The very great success which has exhausted four large editions of this work shows that the author has succeeded in supplying a want felt by a large portion of the profession. It has also enabled him in successive revisions to perfect the details of his plan, and to render the work still more worthy of the favor with which it has been received. In the present edition several hundred brief additions have been made, a number of new subjects have been written upon, especially in connection with the Pathology of the Nervous System, the illustrations have been considerably increased, and a large number of new and carefully selected formulæ for the administration of medicines have been introduced. An account is given, also, in this edition for the first time, of the method of prescribing according to the metrical system, and a section is added upon Eyesight, its Examination and Correction. In presenting this edition, therefore, the publishers feel that it is in every way worthy a continuance of the favor hitherto accorded this work.

WOODBURY (FRANK), M.D.,
Physician to the German Hospital, Philadelphia, late Chief Assist. to Med. Clinic, Jeff. College Hospital, etc.

A HANDBOOK OF THE PRINCIPLES AND PRACTICE OF Medicine; for the use of Students and Practitioners. In one neat volume, royal 12mo., with illustrations. (*In Press.*)

FOTHERGILL (J. MILNER), M.D. Edin., M.R.C.P. Lond.,
Asst. Phys. to the West Lond. Hosp.: Asst. Phys. to the City of Lond. Hosp., etc.

THE PRACTITIONER'S HANDBOOK OF TREATMENT; Or, the Principles of Therapeutics. Second edition, revised and enlarged. In one very neat octavo volume of about 650 pages. Cloth, $4 00; very handsome half Russia, $5 50. (*Just Ready.*)

The junior members of the profession will find in it a work that should not only be read, but carefully studied It will assist them in the proper selection and combination of therapeutical agents best adapted to each case and condition, and enable them to prescribe intelligently and successfully. To do full justice to a work of this scope and character will be impossible in a review of this kind. The book itself must be read to be fully appreciated —*St. Louis Courier of Medicine*, Nov 1880.

The author merits the thanks of every well-educated physician for his efforts toward rationalizing the treatment of diseases upon the scientific basis of physiology. Every chapter, every line, has the impress of a master hand, and while the work is thoroughly scientific in every particular, it presents to the thought ful reader all the charms and beauties of a well-written novel. No physician can well afford to be without this valuable work, for its originality makes it fill a niche in medical literature hitherto vacant.—*Nashville Journ. of Med. and Surg.*, Oct. 1880.

FINLAYSON (JAMES), M.D.,
Physician and Lecturer on Clinical Medicine in the Glasgow Western Infirmary, etc.

CLINICAL DIAGNOSIS; A Handbook for Students and Practitioners of Medicine. In one handsome 12mo. volume, of 546 pages, with 85 illustrations. Cloth, $2 63. (*Lately Issued.*)

The book is an excellent one, clear, concise, convenient, practical It is replete with the very knowledge the student needs when he quits the lecture-room and the laboratory for the ward and sick-room, and does not lack in information that will meet the wants of experienced and older men.—*Phila. Med. Times*, Jan. 4, 1879.

This is one of the really useful books. It is attractive from preface to the final page, and ought to be given a place on every office table, because it contains in a condensed form all that is valuable in semeiology and diagnostics to be found in bulkier volumes, and because in its arrangement and complete index, it is unusually convenient for quick reference in any emergency that may come upon the busy practitioner. —*N. O. Med. Journ.*, Jan. 1879.

WATSON (THOMAS), M.D., &c.

LECTURES ON THE PRINCIPLES AND PRACTICE OF PHYSIC. Delivered at King's College, London. A new American, from the Fifth revised and enlarged English edition. Edited, with additions, and several hundred illustrations, by HENRY HARTSHORNE, M.D., Professor of Hygiene in the University of Pennsylvania. In two large and handsome 8vo. vols. Cloth, $9 00; leather, $11 00.

WILLIAMS'S PULMONARY CONSUMPTION; its Nature, Varieties and Treatment. With an Analysis of One Thousand Cases to exemplify its duration. In one neat octavo volume of about 360 pages; cloth, $2 50.

SLADE ON DIPHTHERIA; its Nature and Treatment, with an account of the History of its Prevalence in various Countries Second and revised edition. In one neat royal 12mo. volume, cloth, $1 25.

WALSHE ON THE DISEASES OF THE HEART AND GREAT VESSELS. Third American Edition. In 1 vol. 8vo., 420 pp., cloth, $3 00.

SMITH ON CONSUMPTION; ITS EARLY AND REMEDIABLE STAGES. 1 vol. 8vo., pp. 264 $2 25.

FULLER ON DISEASES OF THE LUNGS AND AIR-PASSAGES. Their Pathology, Physical Diagnosis, Symptoms and Treatment. From the Second and revised English edition. In one handsome octavo volume of about 500 pages: cloth, $3 50.

REYNOLDS (J. RUSSELL). M.D.,

Prof. of the Principles and Practice of Medicine in Univ. College, London.

A SYSTEM OF MEDICINE WITH NOTES AND ADDITIONS BY HENRY HARTSHORNE, M.D., late Professor of Hygiene in the University of Penna. In three large and handsome octavo volumes, containing 3052 closely printed double-columned pages, with numerous illustrations. *Sold only by subscription.* Price per vol., in cloth, $5 00; in sheep, $6.00: half Russia, raised bands, $6.50. Per set in cloth, $15; sheep, $18; half Russia, $19.50

VOLUME I. (*just ready*) contains GENERAL DISEASES and DISEASES OF THE NERVOUS SYSTEM.
VOLUME II. (*just ready*) contains DISEASES OF RESPIRATORY and CIRCULATORY SYSTEMS.
VOLUME III. (*just ready*) contains DISEASES OF THE DIGESTIVE and BLOOD GLANDULAR SYSTEMS, OF THE URINARY ORGANS, OF THE FEMALE REPRODUCTIVE SYSTEM, and OF THE CUTANEOUS SYSTEM.

Reynolds's SYSTEM OF MEDICINE, recently completed, has acquired, since the first appearance of the first volume, the well-deserved reputation of being the work in which modern British medicine is presented in its fullest and most practical form. This could scarce be otherwise in view of the fact that it is the result of the collaboration of the leading minds of the profession, each subject being treated by some gentleman who is regarded as its highest authority—as for instance, Diseases of the Bladder by Sir HENRY THOMPSON, Malpositions of the Uterus by GRAILY HEWITT, Insanity by HENRY MAUDSLEY, Consumption by J. HUGHES BENNET, Diseases of the Spine by CHARLES BLAND RADCLIFFE, Pericarditis by FRANCIS SIBSON, Alcoholism by FRANCIS E. ANSTIE, Renal Affections by WILLIAM ROBERTS, Asthma by HYDE SALTER, Cerebral Affections by H CHARLTON BASTIAN, Gout and Rheumatism by ALFRED BARING GARROD, Constitutional Syphilis by JONATHAN HUTCHINSON, Diseases of the Stomach by WILSON FOX, Diseases of the Skin by BALMANNO SQUIRE, Affections of the Larynx by MORELL MACKENZIE, Diseases of the Rectum by BLIZARD CURLING, Diabetes by LAUDER BRUNTON, Intestinal Diseases by JOHN SYER BRISTOWE, Catalepsy and Somnambulism by THOMAS KING CHAMBERS, Apoplexy by J. HUGHLINGS JACKSON, Angina Pectoris by Professor GAIRDNER, Emphysema of the Lungs by Sir WILLIAM JENNER, etc etc. All the leading schools in Great Britain have contributed their best men in generous rivalry, to build up this monument of medical science. St. Bartholomew's, Guy's, St Thomas's, University College, St. Mary's, in London, while the Edinburgh, Glasgow, and Manchester schools are equally well represented, the Army Medical School at Netley, the military and naval services, and the public health boards. That a work conceived in such a spirit, and carried out under such auspices should prove an indispensable treasury of facts and experience, suited to the daily wants of the practitioner, was inevitable, and the success which it has enjoyed in England, and the reputation which it has acquired on this side of the Atlantic, have sealed it with the approbation of the two pre-eminently practical nations.

Its large size and high price having kept it beyond the reach of many practitioners in this country who desire to possess it, a demand has arisen for an edition at a price which shall render it accessible to all. To meet this demand the present edition has been undertaken. The five volumes and five thousand pages of the original have by the use of a smaller type and double columns, been compressed into three volumes of over three thousand pages, clearly and handsomely printed, and offered at a price which renders it one of the cheapest works ever presented to the American profession.

But not only is the American edition more convenient and lower priced than the English; it is also better and more complete. Some years having elapsed since the appearance of a portion of the work, additions are required to bring up the subjects to the existing condition of science. Some diseases, also, which are comparatively unimportant in England, require more elaborate treatment to adapt the articles devoted to them to the wants of the American physician; and there are points on which the received practice in this country differs from that adopted abroad. The supplying of these deficiencies has been undertaken by HENRY HARTSHORNE, M.D., late Professor of Hygiene in the University of Pennsylvania, who has endeavored to render the work fully up to the day, and as useful to the American physician as it has proved to be to his English brethren. The number of illustrations has also been largely increased, and no effort spared to render the typographical execution unexceptionable in every respect.

Really too much praise can scarcely be given to this noble book. It is a cyclopædia of medicine written by some of the best men of Europe. It is full of useful information such as one finds frequent need of in one's daily work. As a book of reference it is invaluable. It is up with the times. It is clear and concentrated in style, and its form is worthy of its famous publisher.—*Louisville Med. News*, Jan. 31, 1880.

"Reynolds' System of Medicine" is justly considered the most popular work on the principles and practice of medicine in the English language. The contributors to this work are gentlemen of well-known reputation on both sides of the Atlantic. Each gentleman has striven to make his part of the work as practical as possible, and the information contained is such as is needed by the busy practitioner.—*St. Louis Med. and Surg. Journ.*, Jan. '80.

Dr. Hartshorne has made ample additions and revisions, all of which give increased value to the volume, and render it more useful to the American practitioner. There is no volume in English medical literature more valuable, and every purchaser will, on becoming familiar with it, congratulate himself on the possession of this vast storehouse of information, in regard to so many of the subjects with which he should be familiar.—*Gaillard's Med. Journ.*, Feb. 1880.

There is no medical work which we have in times past more frequently and fully consulted when perplexed by doubts as to treatment, or by having unusual or apparently inexplicable symptoms presented to us than "Reynolds' System of Medicine." Among its contributors are gentlemen who are as well known by reputation upon this side of the Atlantic as in Great Britain, and whose right to speak with authority upon the subjects about which they have written, is recognized the world over. They have evidently striven to make their essays as practical as possible, and while these are sufficiently full to entitle them to the name of monographs, they are not loaded down with such an amount of detail as to render them wearisome to the general reader. In a word, they contain just that kind of information which the busy practitioner frequently finds himself in need of. In order that any deficiencies may be supplied, the publishers have committed the preparation of the book for the press to Dr. Henry Hartshorne, whose judicious notes distributed throughout the volume afford abundant evidence of the thoroughness of the revision to which he has subjected it.—*Am. Jour. Med. Sciences*, Jan. 1880.

BARTHOLOW (ROBERTS), A.M., M.D. LL.D.

Prof. of Materia Medica and General Therapeutics in the Jeff. Med. Coll. of Phila., &c.

A PRACTICAL TREATISE ON ELECTRICITY IN ITS APPLICATION TO MEDICINE.

In one very handsome 8vo. volume of about 270 pages, with 98 illustrations. Cloth, $2 50. (*Just ready.*)

EXTRACT FROM THE AUTHOR'S PREFACE.

I have attempted in the preparation of this work to avoid these errors; to prepare one so simple in statement that a student without previous acquaintance with the subject, may readily master the essentials; so complete as to embrace the whole subject of medical electricity, and so condensed as to be complete in a moderate compass. I have endeavored to keep constantly in view the needs of the two classes for whom the work is prepared—students and practitioners. I have assumed an entire unacquaintance with the elements of the subject as the point of departure—for I am addressing those who have either failed to acquire this preliminary knowledge, or having acquired it, find that after the lapse of years, it has become misty and confused. In the accounts of electrical phenomena I have adhered to the modes of expression with which the medical electrical text-books have made us familiar.

This book, then, must be regarded as the exposition of electricity as a remedial agent, made by a medical practitioner for the use of medical practitioners. No claim is made on the ground of pure science. It is believed, however, that the work makes an adequate presentation of the subject, regarding electricity as a remedial agent—as one of the means employed for the treatment and cure of disease.

So far as we know, the need of a clear, simple, untechnical, reliable, concise, and modern treatise upon the subject of medical electricity is only supplied by the volume under consideration. It is not too much to say that, if availed of, it will render accessible to a vast number of members of the profession a therapeutic agent of the greatest value, but which has heretofore been practically of no use whatever to them.—*Maryland Med. Journal*, June 1, 1881.

We have not yet come across a book that can compare with this in clearness and simplicity of statement. We have for a long time needed a text-book on medical electricity, condensed and yet complete, and this want has been well supplied by the distinguished author. The illustrations are elegant, and the book as a whole is a valuable addition to the collection of any student or practitioner.—*Buffalo Med. and Surg. Journal*, June, 1881.

As a whole, the book must be looked upon as an exposition of electricity for remedial purposes, written by a medical practitioner for the use of medical practitioners. From this standpoint the work is worthy of the careful study of all who desire to investigate this subject for purely practical purposes. This work meets a want of very many students and medical practitioners. We greatly err if it be not gladly welcomed by them. The author, from his long experience as a practitioner, is admirably fitted to perform the task of writing a work of this kind for this special class of men.—*Detroit Lancet*, June, 1881.

This book is expressive of careful research and a nice discrimination in the selection of such matter from that at the author's command as is best adapted for the guidance and instruction of the physician whose interest in electricity is proportionate to its practical bearing on diagnosis and treatment. It is thorough, it is accurate, it is readable, and above all is essentially utilizable, if we may use the word, and renders easy of access to the general practitioner the *modus operandi* of employing this very valuable therapeutic agent.—*N. Y. Medical Gaz.*, June 11, 1881.

MITCHELL (S. WEIR), M.D.,

Phys. to Orthopædic Hospital and the Infirmary for Dis. of the Nervous System, Phila., &c. &c.

LECTURES ON DISEASES OF THE NERVOUS SYSTEM, ESPECIALLY IN WOMEN.

In one very handsome 12mo volume of about 250 pages, with five lithographic plates. Cloth, $1 75 (*Just Ready*)

The life-long devotion of the author to the subjects discussed in this volume has rendered it eminently desirable that the results of his labors should be embodied for the benefit of those who may experience the difficulties connected with the treatment of this class of disease. Many of these lectures are fresh studies of hysterical affections; others treat of the modifications his views have undergone in regard to certain forms of treatment, while, throughout the whole work, he has been careful to keep in view the practical lessons of his cases.

It is a record of a number of very remarkable cases, with acute analyses and discussions, clinical, physiological, and therapeutical. It is a book to which the physician meeting with a new hysterical experience, or in doubt whether his new experience is hysterical, may well turn with a well-grounded hope of finding a parallelism; it will be a new experience, indeed, if no similar one is here recorded —*Phila. Med. Times*, June 4, 1881.

The name of the author is sufficient guarantee that these topics are ably and appreciatively discussed; suffice it to say that the principles of treatment, both hygienic and therapeutic, are clearly indicated. The articles being in the form of clinical lectures, abound in illustrative cases, and are much easier reading than a systematic treatise on the same topics.—*College and Clinical Record*, May 15, 1881.

It is needless to say that these lectures are extraordinarily rich in acute observation and sound instruction. The reputation of the author is a guarantee of that, and no reader will be disappointed. Nor can too much be said in praise of the admirable style of his medical writings, and each of these lectures reads with the finished grace of a polished essay. Indeed, the book throughout is so fascinating a one that it could not fail to be read entire by every one who begins its pages. —*Phila. Med. and Surg. Reporter*, May 7, 1881.

The book throughout is not only intensely entertaining, but it contains a large amount of rare and valuable information. Dr Mitchell has recorded not only the results of his most careful observation, but has added to the knowledge of the subjects treated by his original investigation and practical study. The book is one we can commend to all of our readers —*Maryland Med. Journal*, May 1, 1881.

HAMILTON (ALLAN McLANE), M.D.,

Attending Physician at the Hospital for Epileptics and Paralytics, Blackwell's Island, N.Y., and at the Out-Patients' Department of the New York Hospital.

NERVOUS DISEASES; THEIR DESCRIPTION AND TREATMENT.

Second edition, thoroughly revised and rewritten. In one handsome octavo volume of about 600 pages, with numerous illustrations. (*In Press.*)

MORRIS (MALCOLM), M.D.,
Joint Lecturer on Dermatology, St. Mary's Hospital Med. School.

SKIN DISEASES, Including their Definitions, Symptoms, Diagnosis, Prognosis, Morbid Anatomy and Treatment. A Manual for Students and Practitioners. In one 12mo. volume of over 300 pages. With illustrations. Cloth, $1 75. (*Now Ready.*)

To physicians who would like to know something about skin diseases, so that when a patient presents himself for relief they can make a correct diagnosis and prescribe a rational treatment, we unhesitatingly recommend this little book of Dr. Morris. The affections of the skin are described in a terse, lucid manner, and their several characteristics so plainly set forth that diagnosis will be easy. The treatment in each case is such as the experience of the most eminent dermatologists advise.—*Cincinnati Medical News*, April, 1880.

This is emphatically a learner's book; for we can safely say, so far as our judgment goes, that in the whole range of medical literature of a like scope there is no book which for clearness of expression and methodical arrangement is better adapted to promote a rational conception of dermatology, a branch confessedly difficult and perplexing to the beginner.—*St. Louis Courier of Medicine*, April, 1880.

The author of this manual has evidently a full and intimate acquaintance with the literature of dermatology, and with the most recent developments and appliances of cutaneous medicine. He has produced a plain, practical book, by aid of which, who so chooses may train his eye to the recognition of light but significant differences. The descriptions are neither too vague nor over-refined; the directions for treatment are clear and succinct.—*London Brain*, April, 1880.

The author's task has been well done and has produced one of the best recent works upon the difficult subject of which it treats; there is no work published which gives a better view of the elementary facts and principles of dermatology.—*New Orleans Medical and Surgical Journal*, April, 1880.

FOX (TILBURY), M.D., F.R.C.P., and T. C. FOX, B.A., M.R.C.S.,
Physician to the Department for Skin Diseases, University College Hospital.

EPITOME OF SKIN DISEASES. WITH FORMULÆ. FOR STUDENTS AND PRACTITIONERS. Second edition, thoroughly revised and greatly enlarged. In one very handsome 12mo. volume of 216 pages. Cloth, $1 38.

FLINT (AUSTIN), M.D.,
Professor of the Principles and Practice of Medicine in Bellevue Hospital Med. College, N. Y.

A MANUAL OF PERCUSSION AND AUSCULTATION; of the Physical Diagnosis of Diseases of the Lungs and Heart, and of Thoracic Aneurism. Second edition. In one handsome royal 12mo. volume: cloth, $1 63. (*Just Ready.*)

The little work before us has already become a standard one, and has become extensively adopted as a text-book. There is certainly none better. It contains the substance of the lessons which the author has for many years given, in connection with practical instruction in auscultation and percussion, to private classes, composed of medical students and practitioners.—*Cincinnati Med. News*, Feb. 1880.

BY THE SAME AUTHOR.

PHTHISIS: ITS MORBID ANATOMY, ETIOLOGY, SYMPTOMATIC EVENTS AND COMPLICATIONS, FATALITY AND PROGNOSIS, TREATMENT AND PHYSICAL DIAGNOSIS; in a series of Clinical Studies. By AUSTIN FLINT, M.D., Prof. of the Principles and Practice of Medicine in Bellevue Hospital Med. College, New York. In one handsome octavo volume: $3 50.

BY THE SAME AUTHOR.

A PRACTICAL TREATISE ON THE DIAGNOSIS, PATHOLOGY, AND TREATMENT OF DISEASES OF THE HEART. Second revised and enlarged edition. In one octavo volume of 550 pages, with a plate, cloth, $4.

BY THE SAME AUTHOR.

A PRACTICAL TREATISE ON THE PHYSICAL EXPLORATION OF THE CHEST AND THE DIAGNOSIS OF DISEASES AFFECTING THE RESPIRATORY ORGANS. Second and revised edition. In one handsome octavo volume of 595 pages, cloth, $4 50.

BROWN (LENNOX), F.R.C.S. Ed.,
Senior Surgeon to the Central London Throat and Ear Hospital, etc.

THE THROAT AND ITS DISEASES. Second American, from the Second English Edition, thoroughly revised. With one hundred Typical Illustrations in colors, and fifty wood engravings, designed and executed by the author. In one very handsome imperial octavo volume of over 350 pages. (*Preparing.*)

SEILER (CARL), M.D.,
Lecturer on Laryngoscopy at the Univ. of Penna., Chief of the Throat Dispensary at the Univ. Hospital, Phila., etc.

HANDBOOK OF DIAGNOSIS AND TREATMENT OF DISEASES OF THE THROAT AND NASAL CAVITIES. In one handsome royal 12mo. volume, of 156 pages, with 35 illustrations; cloth, $1. (*Lately Issued.*)

We most heartily commend this book as showing sound judgment in practice, and perfect familiarity with the literature of the specialty it so ably epitomises.—*Philada. Med. Times*, July 5, 1879.

A convenient little handbook, clear, concise, and accurate in its method, and admirably fulfilling its purpose of bringing the subject of which it treats within the comprehension of the general practitioner.—*N. O. Med. Jour.*, June, 1879.

CLINICAL OBSERVATIONS ON FUNCTIONAL NERVOUS DISORDERS By C. HANDFIELD JONES, M.D., Physician to St. Mary's Hospital, &c. Second American Edition. In one handsome octavo volume of 348 pages, cloth, $3 25.

HILLIER'S HANDBOOK OF SKIN DISEASES, for Students and Practitioners. Second Am. Ed. In one royal 12mo. vol. of 358 pp. With illustrations. Cloth, $2 25.

BUMSTEAD (FREEMAN J.), M.D., LL.D.,

Late Professor of Venereal Diseases at the Col. of Phys. and Surg., New York, &c.

THE PATHOLOGY AND TREATMENT OF VENEREAL DISEASES.

Including the results of recent investigations upon the subject. Fourth Edition, revised and largely rewritten with the co-operation of R. W. Taylor, M.D., of New York, Prof. of Dermatology in the Univ. of Vt. In one large and handsome octavo volume of 835 pages, with 138 illustrations. Cloth, $4 75; leather, $5 75; half Russia, $6 25. (*Now Ready.*)

We have to congratulate our countrymen upon the truly valuable addition which they have made to American literature. The careful estimate of the value of the volume, which we have made, justifies us in declaring that this is the best treatise on venereal diseases in the English language, and we might add, if there is a better in any other tongue we cannot name it; there are certainly no books in which the student or the general practitioner can find such an excellent *résumé* of the literature of any topic, and such practical suggestions regarding the treatment of the various complications of every venereal disease. We take pleasure in repeating that we believe this to be the best treatise on venereal disease in the English language, and we congratulate the authors upon their brilliant addition to American medical literature.—*Chicago Med. Journal and Examiner*, February, 1880.

It is, without exception, the most valuable single work on all branches of the subject of which it treats in any language. The pathology is sound, the work is, at the same time, in the highest degree practical, and the hints that he will get from it for the management of any one case, at all obscure or obstinate, will more than repay him for the outlay.—*Archives of Medicine*, April, 1880.

This new classical work on venereal disease comes to us in its fourth edition rewritten, enlarged, and materially improved in every way. Dr. Taylor, as we had every reason to expect, has performed this part of his work with unusual excellence. We feel that what has been written has done but scanty justice to the merits of this truly great treatise.—*St. Louis Courier of Medicine*, Feb. 1880

We find that we have here practically a new book—that the statement of the title page, as to the fact that it has been largely rewritten, is a sufficiently modest announcement for the important changes in the text. After a thorough examination of the present edition, we can assert confidently that the enormous labor we have described has been here most faithfully and conscientiously performed.—*Amer. Journ. Med. Sci.*, Jan. 1880.

It is one of the best general treatises on venereal diseases with which we are acquainted, and is especially to be recommended as a guide to the treatment of syphilis.—*London Practitioner*, March, 1880.

GROSS (SAMUEL W.), A.M., M.D.,

Lecturer on Genito-Urinary and Venereal Diseases in the Jefferson Medical College, Phila.

A PRACTICAL TREATISE ON IMPOTENCE, STERILITY AND ALLIED DISORDERS OF THE MALE SEXUAL ORGANS.

In one very handsome octavo volume of 174 pages, with 16 illustrations. Cloth, $1 50. (*Just Ready.*)

EXTRACT FROM THE AUTHOR'S PREFACE.

"**My aim has been to supply, in a compact form, practical and strictly scientific information, especially adapted to the wants of the general practitioner, in regard to a class of common and grave disorders, upon the correction of which so much of human happiness depends. In the chapter on Sterility, the abnormal conditions of the semen and the causes which deprive it of its fecundating properties are fully considered—a portion of the work intended to supplement the subject of sterility in the female. From answers to letters addressed to many of the most prominent writers in this country on gynæcology, I find that, with few exceptions, the woman alone commands attention in unfruitful marriages. The importance of examining the husband before subjecting the wife to operation will be best appreciated when I state that he is, as a rule, at fault in at least one example in every six.**"

CULLERIER (A.), Surgeon to the Hôpital du Midi. and *BUMSTEAD (FREEMAN J.), Professor of Venereal Diseases in the College of Physicians and Surgeons, N. Y.*

AN ATLAS OF VENEREAL DISEASES. Translated and Edited by FREEMAN J. BUMSTEAD.

In one large imperial 4to. volume of 328 pages, double-columns, with 26 plates, containing about 150 figures, beautifully colored, many of them the size of life; strongly bound in cloth, $17 00; also, in five parts, stout wrappers, at $3 per part.

Anticipating a very large sale for this work, it is offered at the very low price of THREE DOLLARS a Part, thus placing it within the reach of all who are interested in this department of practice. Gentlemen desiring early impressions of the plates would do well to order it without delay. A specimen of the plates and text sent free by mail, on receipt of 25 cents.

LEE'S LECTURES ON SYPHILIS AND SOME FORMS OF LOCAL DISEASE AFFECTING PRINCIPALLY THE ORGANS OF GENERATION. In one handsome octavo volume; cloth, $2 25.

CONDIE'S PRACTICAL TREATISE ON THE DISEASES OF CHILDREN. Sixth edition, revised and augmented. In one large octavo volume of nearly 800 closely-printed pages, cloth, $5 25; leather $6 25

WILSON'S STUDENT'S BOOK OF CUTANEOUS MEDICINE and DISEASES OF THE SKIN. In one very handsome royal 12mo volume. $3 50

CHAMBERS'S MANUAL OF DIET AND REGIMEN IN HEALTH AND SICKNESS. In one handsome octavo volume. Cloth, $2 75

BASHAM ON RENAL DISEASES: a Clinical Guide to their Diagnosis and Treatment. With Illustrations. In one 12mo. vol. of 304 pages, cloth, $2 00.

LECTURES ON THE STUDY OF FEVER. By A. HUDSON, M.D., M.R.I.A.; Physician to the Meath Hospital. In one vol 8vo., cloth, $2 50.

A TREATISE ON FEVER. By ROBERT D. LYONS, K.C.C. In one octavo volume of 362 pages, cloth $2 25.

HILL ON SYPHILIS AND LOCAL CONTAGIOUS DISORDERS. In one handsome octavo volume; cloth $3 25.

SMITH'S PRACTICAL TREATISE ON THE WASTING DISEASES OF INFANCY AND CHILDHOOD. Second American, from the Second revised and enlarged English edition. In one handsome octavo volume, cloth, $2 50.

LA ROCHE ON PNEUMONIA. 1 vol. 8vo., cloth, of 500 pages. Price, $3 00.

SMITH (*J. LEWIS*), *M.D.*,

Clinical Professor of Diseases of Children in the Bellevue Hospital Med. College, N. Y.

A COMPLETE PRACTICAL TREATISE ON THE DISEASES OF CHILDREN. Fifth Edition, thoroughly revised and rewritten. In one handsome octavo volume of 836 pages, with illustrations. Cloth, $4 50; leather, $5 50; very handsome half Russia, raised bands, $6. (*Just Ready.*)

The opportunity afforded the author by the call for a new edition of his treatise on the Diseases of Children has been taken advantage of to render the volume in every respect worthy a continuance of the profession's confidence with which it has been favored in the past. Many portions of the work have been entirely rewritten, several additional diseases treated of, and much new matter introduced; but by the employment of a more condensed style of letter, the size of the work has not been materially enlarged. It will be observed that the very moderate price of the previous edition has not been increased.

KEATING (*JOHN M.*), *M.D.*,

Lecturer on the Diseases of Children at the University of Pennsylvania, etc.

THE MOTHER'S GUIDE IN THE MANAGEMENT AND FEEDING OF INFANTS. In one handsome 12mo. vol. of 118 pages. Cloth, $1 00. (*Now Ready.*)

The title of this little book is well chosen, and Dr. Keating has written a work which should be read, and its precepts followed by every intelligent mother in this country. It is free from all technical terms, the language is clear and distinct, and so carefully written that it cannot fail to become popular. It has always been a mooted question how far it is well to instruct the public, but works like this one will aid the physician immensely, for it saves the time he is constantly giving his patients in instructing them on the subjects here dwelt so thoroughly and practically upon. Dr. Keating has written a practical book, has carefully avoided unnecessary repetition, and I think, successfully instructed the mother in such details of the treatment of her child as devolve upon her; he has studiously omitted giving prescriptions, and instructs the mother when to call upon the doctor, as his duties are totally distinct from hers.—*American Journal of Obstetrics*, October, 1881.

WEST (*CHARLES*), *M.D.*,

Physician to the Hospital for Sick Children, London, &c.

LECTURES ON THE DISEASES OF INFANCY AND CHILDHOOD. Fifth American from the Sixth revised and enlarged English edition. In one large and handsome octavo volume of 678 pages. Cloth, $4 50; leather, $5 50.

BY THE SAME AUTHOR. (*Lately Issued.*)

ON SOME DISORDERS OF THE NERVOUS SYSTEM IN CHILDHOOD; being the Lumleian Lectures delivered at the Royal College of Physicians of London, in March, 1871. In one volume small 12mo., cloth, $1 00.

BY THE SAME AUTHOR.

LECTURES ON THE DISEASES OF WOMEN. Third American, from the Third London edition. In one neat octavo volume of about 550 pages, cloth, $3 75; leather, $4 75.

SWAYNE (*JOSEPH GRIFFITHS*), *M.D.*,

Physician-Accoucheur to the British General Hospital, &c.

OBSTETRIC APHORISMS FOR THE USE OF STUDENTS COMMENCING MIDWIFERY PRACTICE. Second American, from the Fifth and Revised London Edition with Additions by E. R. HUTCHINS, M.D. With Illustrations. In one neat 12mo. volume. Cloth, $1 25.

CHURCHILL ON THE PUERPERAL FEVER AND OTHER DISEASES PECULIAR TO WOMEN. 1 vol. 8vo., pp 450, cloth $2 50.

DEWEES'S TREATISE ON THE DISEASES OF FEMALES. With illustrations. Eleventh Edition, with the Author's last improvements and corrections. In one octavo volume of 536 pages, with plates, cloth. $3 00.

MEIGS ON THE NATURE, SIGNS AND TREATMENT OF CHILDBED FEVER 1 vol. 8vo., pp. 365, cloth. $2 00.

ASHWELL'S PRACTICAL TREATISE ON THE DISEASES PECULIAR TO WOMEN. Third American, from the Third and revised London edition. 1 vol. 8vo., pp. 528, cloth. $3 50.

WINCKEL (*F.*),

Professor and Director of the Gynæcological Clinic in the University of Rostock.

A COMPLETE TREATISE ON THE PATHOLOGY AND TREATMENT OF CHILDBED, for Students and Practitioners. Translated, with the consent of the author, from the Second German Edition, by JAMES READ CHADWICK, M.D. In one octavo volume. Cloth, $4 00.

MONTGOMERY'S EXPOSITION OF THE SIGNS AND SYMPTOMS OF PREGNANCY. With two exquisite colored plates, and numerous wood-cuts. In 1 vol. 8vo., of nearly 600 pp., cloth, $3 75.

RIGBY'S SYSTEM OF MIDWIFERY. With notes and Additional Illustrations. Second American edition. One volume octavo, cloth, 422 pages, $2 50.

THOMAS (*T. GAILLARD*), *M.D.*,

Professor of Obstetrics, &c., in the College of Physicians and Surgeons, N. Y., &c

A PRACTICAL TREATISE ON THE DISEASES OF WOMEN. Fifth Edition, thoroughly revised and rewritten. In one large and handsome octavo volume of over 800 pages, with 266 illustrations. Cloth, $5; leather, $6; very handsome half Russia, raised bands, $6 50. (*Just Ready.*)

The author has taken advantage of the opportunity afforded by the call for a new edition of this work to render it worthy a continuance of the very remarkable favor with which it has been received. Every portion of the work has been carefully revised, very much of it has been rewritten, and additions and alterations introduced wherever the advance of science and the increased experience of the author have shown them desirable. At the same time special care has been exercised to avoid undue increase in the size of the volume. To accommodate the numerous additions a more condensed but very clear letter has been used, notwithstanding which, the number of pages has been increased by more than fifty. The series of illustrations has been extensively changed; many which seemed to be superfluous have been omitted, and a large number of new and superior drawings have been inserted. In its improved form, therefore, it is hoped that the volume will maintain the character it has acquired of a standard authority on every detail of its important subject.

An examination of the work will satisfy that it is one of great merit. It is not a mere compilation from other works, but is the fruit of the ripe thought, sound judgment, and critical observations of a learned, scientific man. It is a treasury of knowledge of the department of medicine to which it is devoted In its present revised state it certainly holds a foremost position as a gynæcological work, and will continue to be regarded as a standard authority —*Cincinnati Med. News*, Dec. 1880.

This work needs no introduction to any of the civilized nations of the world. The edition before us adds to the strength of former volumes. With the wisdom of a master teacher he here gives the results that, in his judgment, are most trustworthy at the present time. In its own place it has no rival, because the author is the best teacher on this subject to the masses of the profession As hitherto this work will be the text-book on diseases of women We only wish that in other branches of medicine as capable teachers could be found to write our text-books.—*Detroit Lancet*, Jan. 1881.

Since its first appearance, twelve years ago, until the present day, it has held a position of high regard, and is generally conceded to be one of the most practical and trustworthy volumes yet presented to the physician and student in the department of gynæcology The work embodies not only its author's large experience, but reflects his careful study among other authorities in this branch, both at home and abroad Dr. Thomas is an able and conscientious teacher. His writings convey his meaning in the same practical and instructive manner. The last edition of this work is fresh from his pen, with decided changes and improvements over former editions. His book presents generally accepted facts, and as a guide to the student is more useful and reliable than any work in the language on diseases of women. This last edition will add new laurels to those already won. — *Md. Med. Journ.*, Nov. 15, 1880

It has been enlarged and carefully revised. The author has brought it fully abreast with the times, and as the wave of gynæcological progression has been widespread and rapid during the twelve years that have elapsed since the issue of the first edition, one can conceive of the great improvement this edition must be upon the earlier. It is a condensed encyclopædia of gynæcological medicine. The style of arrangement, the masterly manner in which each subject is treated, and the honest convictions derived from probably the largest clinical experience in that specialty of any in this country, all serve to commend it in the highest terms to the practitioner. —*Nashville Journ. of Med. and Surg.*, Jan. 1881.

EDIS (*ARTHUR W.*), *M.D. Lond., F.R.C.P., M.R.C.S.*

Assist. Obstetric Physician to Middlesex Hospital, late Physician to British Lying-in Hospital.

THE DISEASES OF WOMEN. Including their Pathology, Causation, Symptoms, Diagnosis, and Treatment. A manual for Students and Practitioners. In one handsome octavo volume with 149 illustrations. (*Shortly.*)

BARNES (*ROBERT*), *M.D., F.R.C.P.*,

Obstetric Physician to St. Thomas's Hospital, &c.

A CLINICAL EXPOSITION OF THE MEDICAL AND SURGICAL DISEASES OF WOMEN. Second American, from the Second Enlarged and Revised English Edition. In one handsome octavo volume, of 784 pages, with 181 illustrations. Cloth, $4 50; leather, $5 50; half Russia, $6. (*Lately Issued.*)

Dr. Barnes stands at the head of his profession in the old country, and it requires but scant scrutiny of his book to show that it has been sketched by a master. It is plain, practical common sense; shows very deep research without being pedantic; is eminently calculated to inspire enthusiasm without inculcating rashness; points out the dangers to be avoided as well as the success to be achieved in the various operations connected with this branch of medicine; and will do much to smooth the rugged path of the young gynæcologist and relieve the perplexity of the man of mature years. — *Canadian Journ. of Med. Science*, Nov. 1878.

Dr. Barnes's work is one of a practical character, largely illustrated from cases in his own experience, but by no means confined to such, as will be learned from the fact that he quotes from no less than 628 medical authors in numerous countries. Coming from such an author, it is not necessary to say that the work is a valuable one, and should be largely consulted by the profession.—*Am. Supp. Obstetrical Journ. Gt. Britain and Ireland*, Oct. 1878.

HODGE (*HUGH L.*), *M.D.*,

Emeritus Professor of Obstetrics, &c., in the University of Pennsylvania.

ON DISEASES PECULIAR TO WOMEN; including Displacements of the Uterus. With original illustrations. Second edition, revised and enlarged. In one beautifully printed octavo volume of 531 pages, cloth, $4 50.

EMMET (*THOMAS ADDIS*), *M.D.*,

Surgeon to the Woman's Hospital, New York, etc.

THE PRINCIPLES AND PRACTICE OF GYNÆCOLOGY, for the use of Students and Practitioners of Medicine. Second Edition. Thoroughly Revised. In one large and very handsome octavo volume of 875 pages, with 133 illustrations. Cloth, $5; leather, $6; half Russia, raised bands, $6 50. (*Just Ready.*)

PREFACE TO THE SECOND EDITION.

The unusually rapid exhaustion of a large edition of this work, while flattering to the author as an evidence that his labors have proved acceptable, has in a great measure heightened his sense of responsibility. He has therefore endeavored to take full advantage of the opportunity afforded to him for its revision. Every page has received his earnest scrutiny; the criticisms of his reviewers have been carefully weighed; and while no marked increase has been made in the size of the volume, several portions have been rewritten, and much new matter has been added. In this minute and thorough revision, the labor involved has been much greater than is perhaps apparent in the results, but it has been cheerfully expended in the hope of rendering the work more worthy of the favor which has been accorded to it by the profession.

In no country of the world has gynæcology received more attention than in America. It is, then, with a feeling of pleasure that we welcome a work on diseases of women from so eminent a gynæcologist as Dr. Emmet, and the work is essentially clinical, and leaves a strong impress of the author's individuality. To criticize, with the care it merits, the book throughout, would demand far more space than is at our command. In parting, we can say that the work teems with original ideas, fresh and valuable methods of practice, and is written in a clear and elegant style, worthy of the literary reputation of the country of Longfellow and Oliver Wendell Holmes.—*Brit. Med. Journ.* Feb. 21, 1880.

No gynæcological treatise has appeared which contains an equal amount of original and useful matter; nor does the medical and surgical history of America include a book more novel and useful. The tabular and statistical information which it contains is marvellous, both in quantity and accuracy, and cannot be otherwise than invaluable to future investigators. It is a work which demands not careless reading but profound study. Its value as a contribution to gynæcology is, perhaps, greater than that of all previous literature on the subject combined.—*Chicago Med Gaz.*, April 5, 1880

The wide reputation of the author makes its publication an event in the gynæcological world; and a glance through its pages shows that it is a work to be studied with care. . . . It must always be a work to be carefully studied and frequently consulted by those who practise this branch of our profession.—*Lond. Med. Times and Gaz.*, Jan. 10, 1880.

The character of the work is too well known to require extended notice—suffice it to say that no recent work upon any subject has attained such great popularity so rapidly. As a work of general reference upon the subject of Diseases of Women it is invaluable. As a record of the largest clinical experience and observation it has no equal. No physician who pretends to keep up with the advances of this department of medicine can afford to be without it.—*Nashville Journ. of Medicine and Surgery*, May, 1880.

DUNCAN (*J. MATTHEWS*), *M.D., LL.D., F.R.S.E., etc.*

CLINICAL LECTURES ON THE DISEASES OF WOMEN, Delivered in Saint Bartholomew's Hospital. In one very neat octavo volume of 173 pages. Cloth, $1 50. (*Just Ready.*)

They are in every way worthy of their author; indeed, we look upon them as among the most valuable of his contributions They are all upon matters of great interest to the general practitioner Some of them deal with subjects that are not, as a rule, adequately handled in the text-books; others of them, while bearing upon topics that are usually treated of at length in such works, yet bear such a stamp of individuality that, if widely read, as they certainly deserve to be, they cannot fail to exert a wholesome restraint upon the undue eagerness with which many young physicians seem bent upon following the wild teachings which so infest the gynæcology of the present day.—*N. Y. Med. Journ.*, March, 1880.

The author is a remarkably clear lecturer, and his discussion of symptoms and treatment is full and suggestive. It will be a work which will not fail to be read with benefit by practitioners as well as by students.—*Phila. Med. and Surg. Reporter*, Feb. 7, 1880.

We have read this book with a great deal of pleasure. It is full of good things. The hints on pathology and treatment scattered through the book are sound, trustworthy, and of great value. A healthy scepticism, a large experience, and a clear judgment are everywhere manifest. Instead of bristling with advice of doubtful value and unsound character, the book is in every respect a safe guide.—*The London Lancet*, Jan. 21, 1880.

RAMSBOTHAM (*FRANCIS H.*), *M.D.*

THE PRINCIPLES AND PRACTICE OF OBSTETRIC MEDICINE AND SURGERY, in reference to the Process of Parturition. A new and enlarged edition, thoroughly revised by the author. With additions by W. V. KEATING, M. D., Professor of Obstetrics, &c., in the Jefferson Medical College, Philadelphia. In one large and handsome imperial octavo volume of 650 pages, strongly bound in leather, with raised bands; with sixty-four beautiful plates, and numerous wood-cuts in the text, containing in all nearly 200 large and beautiful figures. $7 00

PARRY (*JOHN S.*), *M.D.*,

Obstetrician to the Philadelphia Hospital, Vice-Pres. of the Obstet Society of Philadelphia.

EXTRA-UTERINE PREGNANCY: ITS CLINICAL HISTORY, DIAGNOSIS, PROGNOSIS AND TREATMENT. In one handsome octavo volume. Cloth, $2 50.

TANNER (*THOMAS H.*), *M.D.*

ON THE SIGNS AND DISEASES OF PREGNANCY. First American from the Second and Enlarged English Edition. With four colored plates and illustrations on wood. In one handsome octavo volume of about 500 pages, cloth, $4 25.

LEISHMAN (*WILLIAM*), *M.D.*,

Regius Professor of Midwifery in the University of Glasgow, &c.

A SYSTEM OF MIDWIFERY, INCLUDING THE DISEASES OF PREGNANCY AND THE PUERPERAL STATE.

Third American edition, revised by the Author, with additions by JOHN S. PARRY, M.D., Obstetrician to the Philadelphia Hospital, &c. In one large and very handsome octavo volume, of 733 pages, with over two hundred illustrations. Cloth, $4 50; leather, $5 50; half Russia, $6. (*Just Ready*)

Few works on this subject have met with as great a demand as this one appears to have. To judge by the frequency with which its author's views are quoted, and its statements referred to in obstetrical literature, one would judge that there are few physicians devoting much attention to obstetrics who are without it. The author is evidently a man of ripe experience and conservative views, and in no branch of medicine are these more valuable than in this.—*New Remedies*, Jan. 1880.

We gladly welcome the new edition of this excellent text book of midwifery. The former editions have been most favorably received by the profession on both sides of the Atlantic In the preparation of the present edition the author has made such alterations as the progress of obstetrical science seems to require, and we cannot but admire the ability with which the task has been performed. We consider it an admirable text-book for students during their attendance upon lectures, and have great pleasure in recommending it. As an exponent of the midwifery of the present day it has no superior in the English language.—*Canada Lancet*, Jan. 1880.

To the American student the work before us must prove admirably adapted, complete in all its parts, essentially modern in its teachings and with demonstrations noted for clearness and precision, it will gain in favor and be recognized as a work of standard merit The work cannot fail to be popular, and is cordially recommended.—*N. O. Med. and Surg. Journ.*, March, 1880.

PLAYFAIR (*W. S.*), *M.D.*, *F.R.C.P.*,

Professor of Obstetric Medicine in King's College, etc. etc.

A TREATISE ON THE SCIENCE AND PRACTICE OF MIDWIFERY.

Third American edition, revised by the author. Edited, with additions, by ROBERT P. HARRIS, M.D. In one handsome octavo volume of about 700 pages, with nearly 200 illustrations. Cloth, $4; leather, $5; half Russia, $5 50. (*Just Ready*)

The medical profession has now the opportunity of adding to their stock of standard medical works one of the best volumes on midwifery ever published. The subject is taken up with a master hand. The part devoted to laborin all its various presentations, the management and results, is admirably arranged, and the views entertained will be found essentially modern, and the opinions expressed trustworthy The work abounds with plates, illustrating various obstetrical positions; they are admirably wrought, and afford great assistance to the student.—*N. O. Med. and Surg. Journ.*, March, 1880.

If inquired of by a medical student what work on obstetrics we should recommend for him, as *par excellence* we would n doubtedly advise him to choose Playfair's. It is of convenient size, but what is of chief importance, its treatment of the various subjects is concise and plain. While the discussions and descriptions are sufficiently elaborate to render a very intelligent idea of them, yet all details not necessary for a full understanding of the subject are omitted.—*Cincinnati Med. News*, Jan. 1880.

The rapidity with which one edition of this work follows another is proof alike of its excellence and of the estimate that the profession has formed of it. It is indeed so well known and so highly valued that nothing need be said of it as a whole. All things considered, we regard this treatise as the very best on Midwifery in the English language.—*N. Y. Medical Journal*, May, 1880

It certainly is an admirable exposition of the Science and Practice of Midwifery. Of course the additions made by the American editor, Dr. R. P. Harris, who never utters an idle word, and whose studious researches in some special departments of obstetrics are so well known to the profession, are of great value.—*The American Practitioner*, April, 1880

BARNES (*FANCOURT*), *M.D.*,

Physician to the General Lying-in Hospital, London.

A MANUAL OF MIDWIFERY FOR MIDWIVES AND MEDICAL STUDENTS.

With 50 illustrations. In one neat royal 12mo. volume of 200 pages; cloth, $1 25. (*Now Ready.*)

PARVIN (*THEOPHILUS*), *M.D.*,

Prof. of Obstetrics and of the Med. and Surg. Diseases of Women in the Med. Coll. of Indiana.

A TREATISE ON MIDWIFERY.

In one very handsome octavo volume of about 550 pages, with numerous illustrations. (*Preparing.*)

HODGE (*HUGH L.*), *M.D.*,

Emeritus Professor of Midwifery, &c., in the University of Pennsylvania, &c.

THE PRINCIPLES AND PRACTICE OF OBSTETRICS.

Illustrated with large lithographic plates containing one hundred and fifty-nine figures from original photographs, and with numerous wood-cuts. In one large and beautifully printed quarto volume of 550 double-columned pages, strongly bound in cloth, $14.

The work of Dr. Hodge is something more than a simple presentation of his particular views in the department of Obstetrics; it is something more than an ordinary treatise on midwifery; it is, in fact, a cyclopædia of midwifery. He has aimed to embody in a single volume the whole science and art of Obstetrics. An elaborate text is combined with accurate and varied pictorial illustrations, so that no fact or principle is left unstated or unexplained. —*Am. Med. Times*, Sept. 3, 1864.

*** Specimens of the plates and letter-press will be forwarded to any address, free by mail, on receipt of six cents in postage stamps.

CHADWICK (*JAMES R.*), *A.M.*, *M.D.*

A MANUAL OF THE DISEASES PECULIAR TO WOMEN.

In one neat volume, royal 12mo., with illustrations. (*Preparing.*)

HAMILTON (FRANK H.) M.D., LL.D.,

Surgeon to the Bellevue Hospital, New York.

A PRACTICAL TREATISE ON FRACTURES AND DISLOCATIONS

Sixth Edition, thoroughly revised, and much improved. In one very handsome octavo volume of over 900 pages, with 352 illustrations. Cloth, $5 50; leather, $6 50; half Russia, raised bands, $7 00. (*Just Ready.*)

So many kind expressions of welcome have been showered upon each successive edition of this valuable treatise, that scarcely anything remains for us to do but to extend the customary cordial greeting. It is the only complete work on the subject of Fractures in the English language. We congratulate the accomplished author on the deserved success of his work, and hope that he may live to have many succeeding editions pass under his skilled supervision.—*Phila. Coll. and Clin. Record*, Nov. 15, 1880.

Universal verdict has pronounced it, humanly speaking, a perfect treatise upon this subject. As it is the only complete and illustrated work in any language treating of fractures and dislocations, it is safe to affirm that every wide-awake surgeon and general practitioner will regard it as indispensable to the safe and pleasant conduct of their professional work.—*Detroit Lancet*, Nov. 15, 1880.

Dr Hamilton has devoted great labor to the study of these subjects. His large experience, extended research, and patient investigation have made him one of the highest authorities among living writers in this branch of surgery. This work is systematic and practical in its arrangement, and presents its subject matter clearly and forcibly to the reader or student.—*Maryland Medical Journal*, Nov. 15, 1880.

The only complete work on its subject in the English tongue, and, indeed, may now be said to be the only work of its kind in any tongue. It would require an exceedingly critical examination to detect in it any particulars in which it might be improved. The work is a monument to American surgery, and will long serve to keep green the memory of its venerable author.—*Michigan Med. News*, Nov. 10, 1851.

ASHHURST (JOHN, Jr.), M.D.,

Prof. of Clinical Surgery, Univ. of Pa., Surgeon to the Episcopal Hospital, Philadelphia.

THE PRINCIPLES AND PRACTICE OF SURGERY.

Second Edition, enlarged and revised. In one very large and handsome octavo volume of over 1000 pages, with 542 illustrations. Cloth, $6; leather, $7; half Russia, $7 50. (*Just Issued.*)

Conscientiousness and thoroughness are two very marked traits of character in the author of this book. Out of these traits largely has grown the success of his mental fruit in the past, and the present offer seems in no wise an exception to what has gone before. The general arrangement of the volume is the same as in the first edition, but every part has been carefully revised, and much new matter added.—*Phila. Med. Times*, Feb. 1, 1879.

The favorable reception of the first edition is a guarantee of the popularity of this edition, which is fresh from the editor's hands with many enlargements and improvements. The author of this work is deservedly popular as an editor and writer, and his contributions to the literature of surgery have gained for him wide reputation. The volume now offered the profession will add new laurels to those already won by previous contributions. We can only add that the work is well arranged, filled with practical matter, and contains in brief and clear language all that is necessary to be learned by the student of surgery whilst in attendance upon lectures, or the general practitioner in his daily routine practice.—*Md. Med. Journal*, Jan. 1879.

The fact that this work has reached a second edition so very soon after the publication of the first one, speaks more highly of its merits than anything we might say in the way of commendation. It seems to have immediately gained the favor of students and physicians.—*Cincin. Med. News*, Jan. '79.

We have previously spoken of Dr. Ashhurst's work in terms of praise. We wish to reiterate those terms here, and to add that no more satisfactory representation of modern surgery has yet fallen from the press. In point of judicial fairness, of power of condensation, of accuracy and conciseness of expression and thoroughly good English, Prof. Ashhurst has no superior among the surgical writers in America.—*Am. Practitioner*, Jan. 1879.

STIMSON (LEWIS A.), A.M., M.D.,

Surgeon to the Presbyterian Hospital.

A MANUAL OF OPERATIVE SURGERY.

In one very handsome royal 12mo. volume of about 500 pages, with 332 illustrations; cloth, $2 50.

The work before us is a well printed, profusely illustrated manual of over four hundred and seventy pages. The novice, by a perusal of the work, will gain a good idea of the general domain of operative surgery, while the practical surgeon has presented to him within a very concise and intelligible form the latest and most approved selections of operative procedure. The precision and conciseness with which the different operations are described enable the author to compress an immense amount of practical information in a very small compass.—*N. Y. Medical Record*, Aug. 3, 1878.

This volume is devoted entirely to operative surgery, and is intended to familiarize the student with the details of operations and the different modes of performing them. The work is handsomely illustrated, and the descriptions are clear and well drawn. It is a clever and useful volume; every student should possess one. The preparation of this work does away with the necessity of pondering over larger works on surgery for descriptions of operations, as it presents in a nut-shell just what is wanted by the surgeon without an elaborate search to find it.—*Md. Med Journal*, Aug. 1878.

The author's conciseness and the repleteness of the work with valuable illustrations entitle it to be classed with the text-books for students of operative surgery, and as one of reference to the practitioner. —*Cincinnati Lancet and Clinic*, July 27, 1878.

SKEY'S OPERATIVE SURGERY. In 1 vol. 8vo. cl., of 650 pages; with about 100 wood-cuts. $3 25.

COOPER'S LECTURES ON THE PRINCIPLES AND PRACTICE OF SURGERY. In 1 vol. 8vo. cl'h, 750 p. $2.

GIBSON'S INSTITUTES AND PRACTICE OF SURGERY. Eighth edit'n, improved and altered. With thirty-four plates. In two handsome octavo volumes, about 1000 pp., leather, raised bands. $6 50.

THE PRINCIPLES AND PRACTICE OF SURGERY. By WILLIAM PIRRIE, F.R.S.E., Professor of Surgery in the University of Aberdeen. Edited by JOHN NEILL, M.D., Professor of Surgery in the Penna. Medical College, Surg'n to the Pennsylvania Hospital, &c. In one very handsome octavo vol. of 780 pages, with 316 illustrations, cloth, $3 75.

MILLER'S PRINCIPLES OF SURGERY. Fourth American, from the Third Edinburgh Edition. In one large 8vo. vol. of 700 pages, with 340 illustrations, cloth, $3 75.

MILLER'S PRACTICE OF SURGERY. Fourth American, from the last Edinburgh Edition. Revised by the American editor. In one large 8vo. vol. of nearly 700 pages, with 364 illustrations: cloth, $3 75.

GROSS (*SAMUEL D.*), *M.D.*,

Professor of Surgery in the Jefferson Medical College of Philadelphia.

A SYSTEM OF SURGERY: Pathological, Diagnostic, Therapeutic and Operative.

Illustrated by upwards of Fourteen Hundred Engravings. Fifth edition, carefully revised and improved. In two large and beautifully printed imperial octavo volumes of about 2300 pp., strongly bound in leather, with raised bands, $15; half Russia, raised bands, $16.

We have seldom read a work with the practical value of which we have been more impressed. Every chapter is so concisely put together, that the busy practitioner, when in difficulty, can at once find the information he requires. His work is cosmopolitan, the surgery of the world being fully represented in it. The work, in fact, is so historically unprejudiced, and so eminently practical, that it is almost a false compliment to say that we believe it to be destined to occupy a foremost place as a work of reference, while a system of surgery like the present system of surgery is the practice of surgeons. The printing and binding of the work is unexceptionable; indeed, it contrasts, in the latter respect, remarkably with English medical and surgical cloth-bound publications, which are generally so wretchedly stitched as to require re-binding before they are any time in use.—*Dub. Journ. of Med. Sci.*, March, 1874.

Dr. Gross's Surgery, a great work, has become still greater, both in size and merit, in its most recent form. The difference in actual number of pages is not more than 130, but the size of the page having been increased to what we believe is technically termed "elephant," there has been room for considerable additions, which, together with the alterations, are improvements.—*Lond. Lancet*, Nov. 16, 1872.

It combines, as perfectly as possible, the qualities of a text-book and work of reference. We think this last edition of Gross's "Surgery," will confirm his title of "*Primus inter Pares.*" It is learned, scholar-like, methodical, precise, and exhaustive. We scarcely think any living man could write so complete and faultless a treatise, or comprehend more solid, instructive matter in the given number of pages. The labor must have been immense, and the work gives evidence of great powers of mind, and the highest order of intellectual discipline and methodical disposition and arrangement of acquired knowledge and personal experience.—*N.Y. Med. Journ.*, Feb. 1873.

As a whole, we regard the work as the representative "System of Surgery" in the English language.—*St. Louis Medical and Surg. Journ.*, Oct. 1872.

The two magnificent volumes before us afford a very complete view of the surgical knowledge of the day. Some years ago we had the pleasure of presenting the first edition of Gross's Surgery to the profession as a work of unrivalled excellence; and now we have the result of years of experience, labor, and study, all condensed upon the great work before us. And to students or practitioners desirous of enriching their library with a treasure of reference, we can simply commend the purchase of these two volumes of immense research.—*Cincinnati Lancet and Observer*, Sept. 1872.

A complete system of surgery—not a mere text-book of operations, but a scientific account of surgical theory and practice in all its departments.—*Brit. and For. Med Chir. Rev.*, Jan. 1873.

BY THE SAME AUTHOR.

A PRACTICAL TREATISE ON THE DISEASES, INJURIES and Malformations of the Urinary Bladder, the Prostate Gland and the Urethra.

Third Edition, thoroughly Revised and Condensed, by SAMUEL W. GROSS, M.D., Surgeon to the Philadelphia Hospital. In one handsome octavo volume of 574 pages, with 170 illustrations: cloth, $4 50.

For reference and general information, the physician or surgeon can find no work that meets their necessities more thoroughly than this, a revised edition of an excellent treatise, and no medical library should be without it. Replete with handsome illustrations and good ideas, it has the unusual advantage of being easily comprehended, by the reasonable and practical manner in which the various subjects are systematized and arranged. We heartily recommend it to the profession as a valuable addition to the important literature of diseases of the urinary organs.—*Atlanta Med. Journ.*, Oct. 1876.

It is with pleasure we now again take up this old work in a decidedly new dress. Indeed, it must be regarded as a new book in very many of its parts. The chapters on "Diseases of the Bladder," "Prostate Body," and "Lithotomy," are splendid specimens of descriptive writing; while the chapter on "Stricture" is one of the most concise and clear that we have ever read.—*New York Med. Journ.*, Nov. 1876.

BY THE SAME AUTHOR.

A PRACTICAL TREATISE ON FOREIGN BODIES IN THE AIR-PASSAGES.

In 1 vol. 8vo., with Illustrations, pp. 468, cloth, $2 75.

COLEMAN (*ALFRED*), *L.R.C.P., F.R.C.S., L.D.S., etc.*

Senior Dental Surgeon and Lecturer on Dental Surgery to St. Bartholomew's Hospital and the Dental College of London.

A MANUAL OF DENTAL SURGERY AND PATHOLOGY.

Thoroughly revised and adapted to the use of American students, by Thomas C. Stellwagen, M.A., M.D., D.D.S., Professor of Physiology at the Philadelphia Dental College. In one handsome volume with about 450 illustrations. (*In Press.*)

DRUITT (*ROBERT*), *M.R.C.S., &c.*

THE PRINCIPLES AND PRACTICE OF MODERN SURGERY.

A new and revised American, from the Eighth enlarged and improved London edition. Illustrated with four hundred and thirty-two wood engravings. In one very handsome octavo volume, of nearly 700 large and closely printed pages, cloth, $4 00; leather, $5 00.

In Mr. Druitt's book, though containing only some seven hundred pages, both the principles and the practice of surgery are treated, and so clearly and perspicuously, as to elucidate every important topic. We have examined the book most thoroughly, and can say that this success is well merited. His book, moreover, possesses the inestimable advantages of having the subjects perfectly well arranged and classified and of being written in a style at once clear and succinct.—*Am. Journal of Med. Science*

ASHTON ON THE DISEASES, INJURIES, AND MALFORMATIONS OF THE RECTUM AND ANUS: with remarks on Habitual Constipation. Second American, from the Fourth and enlarged London Edition. With Illustrations. In one 8vo. vol. of 287 pages, cloth, $3 25.

SARGENT ON BANDAGING AND OTHER OPERATIONS OF MINOR SURGERY. New edition, with an additional chapter on Military Surgery. One 12mo. vol. of 383 pages with 184 wood-cuts Cloth, $1 75.

HOLMES (TIMOTHY), M. A.,

Surgeon and Lecturer on Surgery at St. George's Hospital, London.

A SYSTEM OF SURGERY; THEORETICAL AND PRACTICAL.

IN TREATISES BY VARIOUS AUTHORS. AMERICAN EDITION, THOROUGHLY REVISED AND REWRITTEN by JOHN H PACKARD, M.D., Surgeon to the Episcopal and St. Joseph's Hospitals, Philadelphia, assisted by a large corps of the most eminent American surgeons. In three large and very handsome imperial octavo volumes of about 1000 pages each, with over 1000 illustrations on wood and thirteen lithographic plates, beautifully colored. (*Sold only by subscription.*) Price per volume, in cloth, $6 00; in leather, $7 00; in half Russia, $7 50. Per set, in cloth, $18 00; in leather, $21 00; in half Russia, $22 50.

VOLUME I. (*now ready*) contains GENERAL PATHOLOGY, MORBID PROCESSES, INJURIES IN GENERAL, COMPLICATIONS OF INJURIES AND INJURIES OF REGIONS.

VOLUME II. (*nearly ready*) contains DISEASES OF ORGANS OF SPECIAL SENSE, CIRCULATORY SYSTEM, DIGESTIVE TRACT AND GENITO-URINARY ORGANS.

VOLUME III. (*shortly*) contains DISEASES OF THE RESPIRATORY ORGANS, JOINTS, BONES, AND MUSCLES, OPERATIVE AND MINOR SURGERY, GUNSHOT WOUNDS, HOSPITALS AND MISCELLANEOUS SUBJECTS.

This great work, issued some years since in England, has won such universal confidence wherever the language is spoken, that its republication here, in a form more thoroughly adapted to the wants of the American practitioner, has seemed to be a duty owing to the profession.

To accomplish this, the aid has been invited of thirty-three of the most distinguished gentlemen, in every part of the country, and for more than a year they have been assiduously engaged upon the task. Though the original work presents the combined labor of the most eminent members of all the most prominent schools of England, yet the lapse of time since the appearance of the last edition, the progress of science, and the peculiarities of American practice, have rendered necessary a most careful, thorough, and searching revision. Each article has been placed in the hands of a gentleman specially competent to treat its subject, and no labor has been spared to bring each one up to the foremost level of the times, and to adapt it thoroughly to the practice of the country. In certain cases, this has rendered necessary the substitution of an entirely new essay for the original, as in the case of the articles on Skin Diseases, and on Diseases of the Absorbent System, where the views of the authors have been superseded by the advance of medical science, and new articles have therefore been prepared by Drs. ARTHUR VAN HARLINGEN and S. C. BUSEY, respectively. So also in the case of Anæsthetics, in the use of which American practice differs from that of England, the original has been supplemented with a new essay by J. C. REEVE, M.D., treating not only of the employment of ether and chloroform, but of the other anæsthetic agents of more recent discovery. The same careful and conscientious revision has been pursued throughout, leading to an increase of nearly one-fourth in matter, while the series of illustrations has been more than doubled, and the whole is presented as a complete exponent of British and American Surgery, adapted to the daily needs of the working practitioner.

In order to bring it within the reach of every member of the profession, the five volumes of the original have been compressed into three, by employing a double-columned imperial octavo page, and in this improved form it is offered at less than one half the price of the original. It is beautifully printed on handsome laid paper and forms a worthy companion to REYNOLDS'S "SYSTEM OF MEDICINE," which has met with so much favor in every section of the country.

The work will be sold by subscription only, and in due time every member of the profession will be called upon and offered an opportunity to subscribe.

The few notices appended will serve to indicate the hearty approval accorded to the unrevised edition on its appearance some years since:—

There is so much that is instructive, even to the experienced practitioner, in their practical and discriminating manner of dealing with mooted questions, none of which seem to be neglected; their abundant illustrations, drawn at once from an unlimited field of hospital experience, and their candid and sensible mode of handling the whole subject, that these particular portions of the work possess a value which places them far above any publication on the same topics yet issued in the language.—*Am. Journ. Med. Sciences.*

The enumeration of the treatises, and the names of the surgical writers from whose pens they proceed, suffice to show that this is no ordinary book, and that in the thousand pages of this goodly volume lies a store of information such as no other surgical work in the language can pretend to offer. Those who are acquainted with the special researches and publications of the respective authors will not fail to notice that by a judicious exercise of editorial discretion, each subject has been entrusted, as far as possible, to a surgeon of the hospitals who is known to have given especial attention to it, and to possess facilities for summing up with authority the accepted opinions of the day, and adding original matter to the stock.—*London Lancet.*

The work must be considered a very complete account of everything connected with the science and practice of surgery. In conclusion we can cordially recommend this work as a valuable addition to the library of the surgeon.—*Edinburgh Medical Journal.*

It is a cyclopædia of surgery of the most complete and extensive character; and we may justly state that its design and execution do great honor to those concerned, and that the large number and high standing of the authors selected for the various monographs render this "System" what it no doubt was intended to be, representative of the actual state of surgical science and art in the country.—*London Lancet.*

In conclusion, we will add that we can most conscientiously recommend the book to every medical practitioner. In recommending the "*System of Surgery*" to our friends who have to deal in surgical cases, we by no means wish to confine our recommendation to them alone. Every practitioner of medicine may cull something worthy of note from a perusal of this volume.—*The British Med. Journal.*

The four volumes remain a monument to the surgical genius of our day. The great majority of metropolitan surgeons of eminence and proved ability are represented in them; and for many years to come, whoever wishes to know the most authoritative words of English Surgical science on most subjects in the domain of surgery must turn to these pages to read what there is set forth. But taken as a whole it is the most important surgical work which has ever issued from the English press.—*London Lancet.*

BRYANT (*THOMAS*), *F.R.C.S.*,
Surgeon to Guy's Hospital.

THE PRACTICE OF SURGERY. Third American, from the Second and Revised English Edition. Thoroughly revised and much improved, by John B. Roberts, M.D. In one large and very handsome imperial octavo volume of over 1000 pages, with 672 illustrations. Cloth, $6 50; leather, $7 50; very handsome half Russia, raised bands, $8 00. (*Just Ready.*)

Mr. Bryant's work has long been a favorite one with surgeons. As its name indicates, it is of a thoroughly practical character. It is distinctly individual in that it gives the results of the author's large and varied experience as an operator and clinical teacher, and is on that account prized deservedly high as an original work. The style is necessarily condensed, the descriptions of surgical diseases brief and to the point. The illustrations are well chosen, and the typical cases of the author's experience are full of interest, and are of more than ordinary value to the working surgeon.—*N. Y. Medical Record*, March 5, 1881.

It is a work especially adapted to the wants of students and practitioners. While not prolix, it affords instruction in sufficient detail for a full understanding of surgical principles and the treatment of surgical diseases. It embraces in its scope all the diseases that are recognized as belonging to surgery, and all traumatic injuries. In discussing these it has seemed to be the aim of the author rather to present the student with practical information, and that alone, than to burden his memory with the views of different writers, however distinguished they might have been. In this edition the whole work has been carefully revised, much of it has been rewritten, important additions have been made to almost every chapter.—*Cincinnati Med. News*, Jan. 1881.

The English edition, from which this is printed, has been carefully revised and rewritten; almost every chapter has received additions, and nearly one hundred new cuts introduced. The labors of the American editor, Dr. John B Roberts, have very much increased the value of the book. He has introduced many new illustrations and much new material not found in the English edition. He has written too with great conciseness, which is a rare virtue in an American editor of an English work. If one could procure or wished only one surgery, this volume would certainly be selected. If he desired two, Erichsen's Surgery would be added, and if he wished a third, Gross's Surgery would justly be the work selected. As the great work of Gross is amply sufficient for the wants of any surgeon, the priority given to Erichsen, and above all others, to this work of Bryant, is no labored eulogy of the last volume but a simple and just statement of its demonstrable and pre-eminent merits.—*Am. Med. Bi-Weekly*, Feb. 26, 1881.

ERICHSEN (*JOHN E.*),
Professor of Surgery in University College, London, etc.

THE SCIENCE AND ART OF SURGERY; being a Treatise on Surgical Injuries, Diseases and Operations. Carefully revised by the Author from the Seventh and enlarged English Edition. Illustrated by eight hundred and sixty-two engravings on wood. In two large and beautiful octavo volumes of nearly 2000 pages: cloth, $8 50; leather, $10 50; half Russia, $11 50. (*Now Ready.*)

Of the many treatises on Surgery which it has been our task to study, or our pleasure to read, there is none which in all points has satisfied us so well as the classic treatise of Erichsen. His polished, clear style, his freedom from prejudice and hobbies, his unsurpassed grasp of his subject, and vast clinical experience, qualify him admirably to write a model text-book. When we wish, at the least cost of time, to learn the most of a topic in surgery, we turn, by preference, to his work. It is a pleasure, therefore, to see that the appreciation of it is general, and has led to the appearance of another edition.—*Med. and Surg. Reporter*, Feb. 2, 1878.

Notwithstanding the increase in size, we observe that much old matter has been omitted. The entire work has been thoroughly written up, and not merely amended by a few extra chapters. A great improvement has been made in the illustrations. One hundred and fifty new ones have been added, and many of the old ones have been redrawn. The author highly appreciates the favor with which his work has been received by American surgeons, and has endeavored to render his latest edition more than ever worthy of their approval. That he has succeeded admirably, must, we think, be the general opinion. We heartily recommend the book to both student and practitioner.—*N. Y. Med. Journal*, Feb. 1878.

The seventh edition is before the world as the last word of surgical science. There may be monographs which excel it upon certain points, but as a conspectus upon surgical principles and practice it is unrivalled. It will well reward practitioners to read it, for it has been a peculiar province of Mr. Erichsen to demonstrate the absolute interdependence of medical and surgical science. We need scarcely add, in conclusion, that we heartily commend the work to students that they may be grounded in a sound faith, and to practitioners as an invaluable guide at the bedside.—*Am. Practitioner*, April, 1878.

For the past twenty years Erichsen's Surgery has maintained its place as the leading text-book, not only in this country, but in Great Britain. That it is able to hold its ground, is abundantly proven by the thoroughness with which the present edition has been revised, and by the large amount of valuable material that has been added. Aside from this, one hundred and fifty new illustrations have been inserted, including quite a number of microscopical appearances of pathological processes. So marked is this change for the better, that the work almost appears as an entirely new one.—*Med. Record*, Feb. 23, 1878.

HOLMES (*TIMOTHY*), *M.D.*,
Surgeon to St. George's Hospital, London.

SURGERY, ITS PRINCIPLES AND PRACTICE. In one handsome octavo volume of nearly 1000 pages, with 411 illustrations. Cloth, $6; leather, $7; half Russia, $7 50.

This is a work which has been looked for on both sides of the Atlantic with much interest. Mr. Holmes is a surgeon of large and varied experience, and one of the best known, and perhaps the most brilliant writer upon surgical subjects in England. It is a book for students—and an admirable one—and for the busy general practitioner. It will give a student all the knowledge needed to pass a rigid examination. The book fairly justifies the high expectations that were formed of it. Its style is clear and forcible, even brilliant at times, and the conciseness needed to bring it within its proper limits has not impaired its force and distinctness.—*N. Y. Med. Record*, April 14, 1876.

It will be found a most excellent epitome of surgery by the general practitioner who has not the time to give attention to more minute and extended works, and to the medical student. In fact, we know of no one we can more cordially recommend. The author has succeeded well in giving a plain and practical account of each surgical injury and disease, and of the treatment which is most commonly advisable. It will no doubt become a popular work in the profession, and especially as a text-book.—*Cincinnati Med. News*, April, 1876.

WELLS (*J. SOELBERG*),

Professor of Ophthalmology in King's College Hospital, &c.

A TREATISE ON DISEASES OF THE EYE. Third American,

from the Third London Edition. Thoroughly revised, with copious additions, by Chas. S. Bull, M.D., Surgeon and Pathologist to the New York Eye and Ear Infirmary. Illustrated with about 250 engravings on wood, and six colored plates Together with selections from the Test-types of Jaeger and Snellen. In one large and very handsome octavo volume of 900 pages. Cloth, $5; leather, $6; half Russia, raised bands, $6 50. (*Just Ready.*)

The long-continued illness of the author, with its fatal termination, has kept this work for some time out of print, and has deprived it of the advantage of the revision which he sought to give it during the last years of his life. This edition has therefore been placed under the editorial supervision of Dr. Bull, who has labored earnestly to introduce in it all the advances which observation and experience have acquired for the theory and practice of ophthalmology since the appearance of the last revision. To accomplish this, considerable additions have been required, and the work is now presented in the confidence that it will fully deserve a continuance of the very marked favor with which it has hitherto been greeted as a complete, but concise, exposition of the principles and facts of its important department of medical science.

The additions made in the previous American editions by Dr. Hays have been retained, including the very full series of illustrations and the test-types of Jaeger and Snellen.

This new edition of Dr. Wells's great work on the eye will be welcomed by the profession at large as well as by the oculist It contains much new matter relating to treatment and pathology, and is brought thoroughly up with the present status of ophthalmology. Its chapter on refraction and accommodation—a subject much discussed of late years, and of great importance—is exceedingly complete.—*Louisville Med. News*, Nov. 13, 1880.

The merits of Wells's treatise on diseases of the eye have been so universally acknowledged, and are so familiar to all who profess to have given any attention to ophthalmic surgery, that any discussion of them at this late day will be a work of supererogation. Very little that is practically useful in recent ophthalmic literature has escaped the editor, and the third American edition is well up to the times. As a text-book on ophthalmic surgery for the English-speaking practitioner, it is without a rival.—*Am. Journ. of Med. Sc.*, Jan. 1881.

The work has justly held a high place in English ophthalmic literature, and at the time of its first appearance was the best treatise of its kind in the language. In the second edition, the author showed industrious research in adding new material from every quarter, and his spirit was eminently candid. A work thus built up by honest effort should not be suffered to die, and we are pleased to receive this third edition from the hands of Dr. Bull. His labor has been arduous, as the very great number of additions bracketed with his initial testify. Under the editorship which the third edition has enjoyed, the work is sure to sustain its good reputation, and to maintain its usefulness.—*N. Y. Med. Journ.*, Jan. 1881.

There is really no work which approaches it in adaptation to the wants of the general practitioner, while the most advanced specialist cannot rise from a perusal of its ample pages without having added to his knowledge. The American editor, Dr. Bull, won his spurs in ophthalmology some time back. His additions to the work of the lamented Wells are many, judicious, and timely, and in just so much have added to its value.—*Am. Practitioner*, Jan. 1881.

NETTLESHIP (*EDWARD*), *F.R.C.S.*,

Ophthalmic Surg. and Lect. on Ophth. Surg. at St. Thomas' Hospital, London.

MANUAL OF OPHTHALMIC MEDICINE. In one royal 12mo.

volume of over 350 pages, with 89 illustrations. Cloth, $2. (*Just Ready.*)

The author is to be congratulated upon the very successful manner in which he has accomplished his task; he has succeeded in being concise without sacrificing clearness, and, including the whole ground covered by more voluminous text-books, has given an excellent *résumé* of all the practical information they contain. We do not hesitate to pronounce Mr. Nettleship's book the best manual on ophthalmic surgery for the use of students and "busy practitioners" with which we are acquainted.—*Am. Jour. Med. Sciences*, April, 1880.

CARTER (*R. BRUDENELL*), *F.R.C.S.*,

Ophthalmic Surgeon to St. George's Hospital, etc.

A PRACTICAL TREATISE ON DISEASES OF THE EYE. Edited,

with test-types and Additions, by JOHN GREEN, M.D. (of St. Louis, Mo.). In one handsome octavo volume of about 500 pages, and 124 illustrations. Cloth, $3 75.

It is with great pleasure that we can endorse the work as a most valuable contribution to practical ophthalmology. Mr. Carter never deviates from the end he has in view, and presents the subject in a clear and concise manner, easy of comprehension, and hence the more valuable. We would especially commend, however, as worthy of high praise, the manner in which the therapeutics of disease of the eye is elaborated, for here the author is particularly clear and practical, where other writers are unfortunately too often deficient. The final chapter is devoted to a discussion of the uses and selection of spectacles, and is admirably compact, plain, and useful, especially the paragraphs on the treatment of presbyopia and myopia. In conclusion, our thanks are due the author for many useful hints in the great subject of ophthalmic surgery and therapeutics, a field where of late years we glean but a few grains of sound wheat from a mass of chaff.—*New York Medical Record*, Oct. 23, 1875.

BROWNE (*EDGAR A.*),

Surgeon to the Liverpool Eye and Ear Infirmary, and to the Dispensary for Skin Diseases.

HOW TO USE THE OPHTHALMOSCOPE. Being Elementary Instructions in Ophthalmoscopy, arranged for the Use of Students. With thirty-five illustrations. In one small volume royal 12mo. of 120 pages: cloth, $1.

LAURENCE'S HANDY-BOOK OF OPHTHALMIC SURGERY, for the use of Practitioners. Second edition, revised and enlarged With numerous illustrations. In one very handsome octavo volume, cloth, $2 75.

LAWSON'S INJURIES TO THE EYE, ORBIT AND EYELIDS: their Immediate and Remote Effects. With about one hundred illustrations. In one very handsome octavo volume, cloth, $3 50.

BURNETT (CHARLES H.), M.A., M.D.,

Aural Surg to the Presb. Hosp., Surgeon-in-charge of the Infir. for Dis. of the Ear, Phila.

THE EAR, ITS ANATOMY, PHYSIOLOGY AND DISEASES.

A Practical Treatise for the Use of Medical Students and Practitioners. In one handsome octavo volume of 615 pages, with eighty-seven illustrations: cloth, $4 50; leather, $5 50; half Russia, $6 00. (*Lately Issued.*)

Foremost among the numerous recent contributions to aural literature will be ranked this work of Dr. Burnett. It is impossible to do justice to this volume of over 600 pages in a necessarily brief notice. It must suffice to add that the book is profusely and accurately illustrated, the references are conscientiously acknowledged, while the result has been to produce a treatise which will henceforth rank with the classic writings of Wilde and Von Tröltsch.—*The Lond. Practitioner*, May, 1879.

On account of the great advances which have been made of late years in otology, and of the increased interest manifested in it, the medical profession will welcome this new work, which presents clearly and concisely its present aspect, whilst clearly indicating the direction in which further researches can be most profitably carried on. Dr. Burnett from his own matured experience, and availing himself of the observations and discoveries of others, has produced a work which, as a text-book, stands *facile princeps* in our language. We had marked several passages as well worthy of quotation and the attention of the general practitioner, but their number and the space at our command forbid. Perhaps it is better, as the book ought to be in the hands of every medical student, and its study will well repay the busy practitioner in the pleasure he will derive from the agreeable style in which many otherwise dry and mostly unknown subjects are treated. To the specialist the work is of the highest value, and his sense of gratitude to Dr. Burnett will we hope, be proportionate to the amount of benefit he can obtain from the careful study of the book, and a constant reference to its trustworthy pages.—*Edinburgh Med. Jour.*, Aug. 1878.

TAYLOR (ALFRED S.), M.D.,

Lecturer on Med. Jurisp. and Chemistry in Guy's Hospital.

A MANUAL OF MEDICAL JURISPRUDENCE. Eighth American edition.

Thoroughly revised and rewritten. Edited by JOHN J. REESE, M.D., Prof. of Med. Jurisp. and Toxicology in the Univ. of Penn. In one large octavo volume of 933 pages, with 70 illustrations. Cloth, $5; leather, $6; half Russia, raised bands, $6 50. (*Just Ready.*)

The American editions of this standard manual have for a long time laid claim to the attention of the profession in this country; and that the profession has recognized this claim with favor is proven by the call for frequent new editions of the work. This one, the eighth, comes before us as embodying the latest thoughts and emendations of Dr. Taylor, upon the subject to which he devoted his life, with an assiduity and success which made him *facile princeps* among English writers on medical jurisprudence. Both the author and the book have made a mark too deep to be affected by criticism, whether it be censure or praise. In this case, however, we should only have to seek for laudatory terms.—*Am. Journ. of Med Sci.*, Jan. 1881.

It is not very often that a medical book reaches its tenth edition, or that the last earthly labor is performed by the author in retouching the work that first came from his hand thirty-five years before. All this, however, has happened in the case of Dr. Taylor and his classical treatise. The pen dropped from the grasp only when the shadows of old age were rapidly deepening into the darkness of death. Under the circumstances, all the journalist has to do is to announce, not criticize the completed task. The value of the gem is too well known to require more than the telling that the master-hand has rebrightened its facets and polished its angles before leaving it as his legacy to his brethren in the profession.—*Phila Med. Times*, Dec. 4, 1880.

It will suffice to remark that this new edition shows the signs of judicious revision. A great number of illustrative medico-legal cases which have occurred since the last edition was published are cited in their proper connection, and add much to the interest and value of the work; they comprise the bulk of the additions to the text. As an indication of the freshness of the work, we notice numerous references to medico-legal experience that has transpired during the year just ended; among these is a comment by the American editor upon that midsummer madness, the Tanner fasting exploit of last August. In these features and in others there is ample evidence that this admirable book will maintain its high place as a standard authority concerning the matters of which it treats.—*Boston Med. and Surg. Journal*, Jan. 13, 1881.

BY THE SAME AUTHOR.

THE PRINCIPLES AND PRACTICE OF MEDICAL JURISPRUDENCE.

Second Edition, Revised, with numerous Illustrations. In two large octavo volumes, cloth, $10 00; leather, $12 00

This great work is now recognized in England as the fullest and most authoritative treatise on every department of its important subject. In laying it, in its improved form, before the American profession, the publishers trust that it will assume the same position in this country.

BY THE SAME AUTHOR.

POISONS IN RELATION TO MEDICAL JURISPRUDENCE AND MEDICINE.

Third American, from the Third and Revised English Edition. In one large octavo volume of 850 pages; cloth, $5 50; leather, $6 50.

The present is based upon the two previous editions; "but the complete revision rendered necessary by time has converted it into a new work." This statement from the preface contains all that it is desired to know in reference to the new edition. The works of this author are already in the library of every physician who is liable to be called upon for medico-legal testimony (and what one is not?), so that all that is required to be known about the present book is that the author has kept it abreast with the times. What makes it now, as always, especially valuable to the practitioner is its conciseness and practical character, only those poisonous substances being described which give rise to legal investigations.—*The Clinic*, Nov. 6, 1875.

Dr. Taylor has brought to bear on the compilation of this volume, stores of learning, experience, and practical acquaintance with his subject, probably far beyond what any other living authority on toxicology could have amassed or utilized. He has fully sustained his reputation by the consummate skill and legal acumen he has displayed in the arrangement of the subject-matter, and the result is a work on Poisons which will be indispensable to every student or practitioner in law and medicine.—*The Dublin Journ. of Med Sc.*, Oct. 1875.

ROBERTS (*WILLIAM*), *M.D.*,
Lecturer on Medicine in the Manchester School of Medicine, &c.

A PRACTICAL TREATISE ON URINARY AND RENAL DISEASES, including Urinary Deposits. Illustrated by numerous cases and engravings. Third American, from the Third Revised and Enlarged London Edition. In one large and handsome octavo volume of over 600 pages. Cloth, $4. (*Just Ready.*)

THOMPSON (*SIR HENRY*),
Surgeon and Professor of Clinical Surgery to University College Hospital.

LECTURES ON DISEASES OF THE URINARY ORGANS. With illustrations on wood. Second American from the Third English Edition. In one neat octavo volume. Cloth, $2 25.

BY THE SAME AUTHOR.

ON THE PATHOLOGY AND TREATMENT OF STRICTURE OF THE URETHRA AND URINARY FISTULÆ. With plates and wood-cuts. From the third and revised English edition. In one very handsome octavo volume, cloth, $3 50.

TUKE (*DANIEL HACK*), *M.D*,
Joint author of The Manual of Psychological Medicine, &c.

ILLUSTRATIONS OF THE INFLUENCE OF THE MIND UPON THE BODY IN HEALTH AND DISEASE. Designed to illustrate the Action of the Imagination. In one handsome octavo volume of 416 pages, cloth, $3 25.

BLANDFORD (*G. FIELDING*), *M.D., F.R.C.P.*,
Lecturer on Psychological Medicine at the School of St. George's Hospital, &c.

INSANITY AND ITS TREATMENT: Lectures on the Treatment, Medical and Legal, of Insane Patients. With a Summary of the Laws in force in the United States on the Confinement of the Insane. By ISAAC RAY, M. D. In one very handsome octavo volume of 471 pages; cloth, $3 25.

It satisfies a want which must have been sorely felt by the busy general practitioners of this country. It takes the form of a manual of clinical description of the various forms of insanity, with a description of the mode of examining persons suspected of insanity. We call particular attention to this feature of the book, as giving it a unique value to the general practitioner. If we pass from theoretical considerations to descriptions of the varieties of insanity as actually seen in practice and the appropriate treatment for them, we find in Dr. Blandford's work a considerable advance over previous writings on the subject. His pictures of the various forms of mental disease are so clear and good that no reader can fail to be struck with their superiority to those given in ordinary manuals in the English language or (so far as our own reading extends) in any other.—*London Practitioner*, Feb. 1871.

LEA (*HENRY C.*).

SUPERSTITION AND FORCE: ESSAYS ON THE WAGER OF LAW, THE WAGER OF BATTLE, THE ORDEAL AND TORTURE. Third Revised and Enlarged Edition. In one handsome royal 12mo. volume of 552 pages. Cloth, $2 50. (*Just Ready.*)

This valuable work is in reality a history of civilization as interpreted by the progress of jurisprudence. . . . In "Superstition and Force" we have a philosophic survey of the long period intervening between primitive barbarity and civilized enlightenment. There is not a chapter in the work that should not be most carefully studied, and however well versed the reader may be in the science of jurisprudence, he will find much in Mr. Lea's volume of which he was previously ignorant. The book is a valuable addition to the literature of social science.—*Westminster Review*, Jan. 1880.

The appearance of a new edition of Mr. Henry C. Lea's "Superstition and Force" is a sign that our highest scholarship is not without honor in its native country. Mr. Lea has met every fresh demand for his work with a careful revision of it, and the present edition is not only fuller and, if possible, more accurate than either of the preceding, but, from the thorough elaboration is more like a harmonious concert and less like a batch of studies.—*The Nation*, Aug. 1, 1878.

Many will be tempted to say that this, like the "Decline and Fall," is one of the uncriticizable books. Its facts are innumerable, its deductions simple and inevitable, and its *chevaux-de-frise* of references bristling and dense enough to make the keenest, stoutest, and best equipped assailant think twice before advancing. Nor is there anything controversial in it to provoke assault. The author is no polemic. Though he obviously feels and thinks strongly, he succeeds in attaining impartiality. Whether looked on as a picture or a mirror, a work such as this has a lasting value.—*Lippincott's Magazine*, Oct. 1878.

BY THE SAME AUTHOR.

STUDIES IN CHURCH HISTORY. THE RISE OF THE TEMPORAL POWER—BENEFIT OF CLERGY—EXCOMMUNICATION. In one large royal 12mo. volume of 516 pp.; cloth, $2 75. (*Lately Published.*)

The story was never told more calmly or with greater learning or wiser thought. We doubt, indeed, if any other study of this field can be compared with this for clearness, accuracy, and power.—*Chicago Examiner*, Dec. 1870.

Mr. Lea's latest work, "Studies in Church History," fully sustains the promise of the first. It deals with three subjects—the Temporal Power, Benefit of Clergy, and Excommunication, the record of which has a peculiar importance for the English student, and is a chapter on Ancient Law likely to be regarded as final. We can hardly pass from our mention of such works as these—with which that on "Sacerdotal Celibacy" should be included—without noting the literary phenomenon that the head of one of the first American houses is also the writer of some of its most original books.—*London Athenæum*, Jan. 7, 1871.
